Biopsy of the left pleura showed slight chronic inflammation in dense collagenous tissue. Ten days after the operation he had a chill, with a rapid pulse and a temperature of 102°F, followed by a dry painful cough and pain on deep inspiration. There was slight ankle edema. No tenderness was elicited in the thighs or calves. The serum protein was 5.8 gm per 100 cc, with an albumin of 2.4 gm and a globulin of 3.4 gm. The prothrombin time was 28 seconds (normal, 22 seconds). The febrile episode lasted three days. He was discharged on the twenty-eighth hospital day.

Fourth admission (four months later). Soon after discharge the nocturia gradually increased so that he urinated every two hours. There were dribbling and some incontinence, followed by dysuria. The prostate was symmetrically enlarged to twice its normal size. A transurethral resection for benign prostatic hyperplasia was performed. Postoperatively he had an immediate episode of nervousness and shaking accompanied by cyanosis but without a chilly sensation, dyspnea or pain. The temperature rose to 104°F. This lasted only a few hours. He was discharged on the fifth postoperative day.

Final admission (two years later). He was apparently well until three days before re-entry, when he developed cough, with malaise and increasing fever.

On physical examination the lips were moderately cyanotic and the skin was flushed and hot. He was breathing hard at a rate of 40 respirations per minute. The right lung over the midportion posteriorly was dull to percussion, with bronchial breathing and inconstant rales in this area. The left cardiac border was 11 cm to the left of the mid-sternal line. The rhythm was irregular, and the rate rapid.

The red-cell count was 5,450,000, and the hemoglobin 16.9 gm. The white-cell count was 16,400, with 92 per cent neutrophils, band forms predominating. The urine had a specific gravity of 1.018 and gave a ++ test for albumin. The sediment contained 25 white cells and a rare red cell per high-power field.

The temperature was 104°F, and the pulse 120. The blood pressure was 100 systolic, 60 diastolic.

X-ray films revealed an area of increased density in the right upper lung field, probably located in the dorsal division of the lower lobe. There was also an ill defined density in the left lower lung

field, with apparent decrease in the size of the left lower lobe and also a line of density extending along the lateral chest wall.

The patient was started on penicillin (32,000 units every two hours). On the day after admission the temperature had fallen to 100°F and the respirations to 25. The patient felt better but was coughing up bloody sputum and had a pulse of 116, despite 0.8 mg of Cedilanid intravenously and 0.4 mg of Purodigin over a twelve-hour period. There was less dullness posteriorly but there were increased fine rales throughout most of the right chest. Abundant Type 3 pneumococci were isolated from the throat.

Two days later the temperature was back to 102°F and he still had rales and was coughing up blood-streaked sputum. Sulfadiazine was started in addition to penicillin. On the seventh hospital day he developed a generalized itching erythematous rash. There was considerable exfoliation over the arms. The pharynx was normal. Sulfadiazine was stopped. Subsequently, the rash improved but the patient's condition continued to deteriorate. He remained cyanotic. He developed shifting dullness in the abdomen, and the liver was palpable two fingerbreadths below the ribs. Rales and rhonchi were constant in all lung fields.

On the eighteenth hospital day, just after he had been taken off the bed pan, he gasped, fell back on the pillow deeply cyanotic and died.

DIFFERENTIAL DIAGNOSIS

DR DONALD S. KING. Four organs were involved in this long story: they took out a benign prostate, and then there were three. The prostate explains satisfactorily the urinary symptoms. The remaining involved areas are the leg—with the fracture many years before and the infection recently occurring around the bone plate—and the lungs and the heart, both of which had given symptoms for four years, long before the recurrence of symptoms in the leg. Of course, the temptation, when one is presented with this story, is to try to combine all three systems in one diagnosis and say that the chest symptoms were embolic phenomena, with the source in the infected area in the leg. But as we shall see, such an explanation is not sufficient to cover all the findings.

So far as the pulmonary symptoms are concerned, there were episodes of fever, and it was real fever, sometimes with chills. At times the high temperature persisted for as long as six weeks. One assumes that the fever came from the lung or the pleura. There was a cough, which was dry except for occasional bloody sputum, nothing is said about pus, foul or otherwise. Then there were attacks of definite pleural pain, which changed to an ache and persisted. Then there was fluid that took a long time to disappear. At one time the fluid was bloody, otherwise it was clear.

pain and was markedly constipated. There was no blood in the stools. Three days before admission, poorly localized abdominal pain again appeared, with pain in the rectum. During this three-day period he had no bowel movements. A few hours before admission he vomited a small amount on three occasions.

The past history revealed that the patient had been constipated for many years, using a laxative daily to obtain a normal bowel movement. For several years he had complained of progressively severer frequency, nocturia and urgency. A year and a half before this admission the prostate was found to be moderately enlarged. A transurethral resection was done, from which he recovered uneventfully.

Physical examination revealed a well developed and nourished man. The skin was warm and moist. The pupils were normal. The heart was not enlarged, and there were no murmurs. There were a few coarse rales at both lung bases. The abdomen was soft, and there was slight tenderness in both lower quadrants. Peristalsis was normal. The prostate was small. The reflexes were normal.

Temperature was 100°F, the pulse 100, and the respirations 25. The blood pressure was 160 systolic, 85 diastolic.

The hemoglobin was 85 per cent. The white-cell count was 14,000. The urine was normal. The nonprotein nitrogen was 31 mg per 100 cc. The total serum protein was 5.8 gm per 100 cc, and the chloride 90 milliequiv per liter. The blood Hinton reaction was negative.

A flat film of the abdomen showed a large amount of gas and retained bowel contents in the large bowel without evidence of obstruction. Several loops of large bowel were dilated. The bones of the lumbar spine showed advanced hypertrophic changes.

A barium enema shortly after admission showed numerous diverticula of the sigmoid. No spasm was observed fluoroscopically. The bowel wall in this area was irregular. The terminal ileum was not visualized. Shortly after the barium enema had been given, the abdomen was noted to be tense and boardlike, with absent peristalsis, and tenderness became generalized.

About two hours later a plain film showed the greater portion of the barium to be retained in the large bowel. A film with the patient standing showed no evidence of air beneath the diaphragm.

An immediate exploratory laparotomy was done.

DIFFERENTIAL DIAGNOSIS

DR. FLORINDO A. SIMEONE. This is the case of a seventy-eight-year-old man who had a lesion which caused partial obstruction of the large intestine and developed a complication necessitating an emergency operation. There is no supporting evidence that the final episode of abdominal spasm and tenderness could have been due to "abdominal apo-

plexy" or to volvulus and strangulation. These possibilities are therefore dismissed, and I believe that it is reasonable to explain the present illness and the final episode on the basis of a single lesion.

One has to decide whether the lesion causing partial obstruction was intrinsic or extrinsic relative to the bowel. The patient had a history of mild urinary-tract obstruction, which might have been due to cancer of the prostate, but this was apparently cured by transurethral resection and there is no evidence of recurrence. Rectal examination on entry showed a normal prostate, and nothing is recorded to suggest a pelvic mass that could have caused obstruction of the large intestine from extrinsic pressure. The roentgenograph apparently did not suggest adynamic ileus, and the negative Hinton reaction rules out the adynamic ileus occasionally seen in *tabes dorsalis*.

We are thus left with a lesion that was probably intrinsic in the large intestine and certainly interfered mechanically with the normal emptying of the bowel. Five important lesions are to be considered in the differential diagnosis of large-bowel obstruction in a man of seventy-eight — malignant tumor, diverticulitis, hernia, volvulus and appendiceal abscess. The lack of signs in the right lower quadrant, the failure to demonstrate a mass and the localization of the nonspastic lesion in the sigmoid by roentgenograph are sufficient to rule out appendicitis with abscess formation. Physical examination and the x-ray findings rule out hernia and volvulus. It remains, therefore, to distinguish between diverticulitis and carcinoma of the sigmoid. Tumors of mesodermal origin in the wall of the large bowel are not considered because they are rare and because they do not lead to perforation without involving the mucosa. Granulomas — tuberculosis and actinomycosis — are also rare in this region and need not be discussed in the absence of more evidence suggesting them. Without more definite evidence concerning the nature of the mucosa in the region of the lesion, one can merely marshal the evidence and then make as good a guess as one can regarding the differentiation of carcinoma and diverticulitis.

The long history of constipation is characteristic of diverticulitis and diverticulosis but does not help us any more than does the demonstration of diverticula by roentgenograph. In fact, if the patient used daily catharsis for years, it is difficult to be sure he was really constipated. Some change took place in the bowel during the three days before admission, however, for then there were no bowel movements. I assume that the change was inflammatory.

The patient was seventy-eight years old. The ages most frequently encountered in diverticulitis are in the decade between fifty and sixty. When these figures are corrected for the incidence of ages in the general population, however, diverticulitis

enlargement of the cervical veins when he was admitted

DR KING He had everything else, I wish he had had that too

DR MALLORY It is obvious that at one period a malignant tumor was strongly considered. Such a possibility unquestionably underlay the biopsy of the pleura

DR KING I grant you that one has to think of malignant tumor in the differential diagnosis, which I did not mention because of time. But the story is too long in duration, and in addition, the patient had a two-year period when he was perfectly well

CLINICAL DIAGNOSES

Lobar pneumonia
Carcinoma of lung?
Arteriosclerotic heart disease
Congestive heart failure
Pulmonary embolism
Ventricular fibrillation?

DR KING'S DIAGNOSES

Tuberculous constrictive pericarditis
Tuberculous pleurisy
Pulmonary tuberculosis
Pneumococcal pneumonia (Type 3)
Pulmonary infarcts
Pulmonary embolus (fatal)
"Pseudo-cirrhosis of liver"

ANATOMICAL DIAGNOSES

Pericarditis, adhesive.
Pleuritis, fibrous left chest
Cirrhosis of liver, toxic
Hydrothorax, right
Infarcts of lung, multiple, recent
Pulmonary emboli, multiple
Bronchopneumonia, organized
Osteomyelitis, healed right fibula
Pancreatitis, chronic

PATHOLOGICAL DISCUSSION

DR MALLORY Dr King made a number of diagnoses, and I have to list a number of pathological findings. I do not believe I can tie mine together any more satisfactorily than he has

There was a constrictive pericarditis. The pericardium was densely fibrous, ranging from 3 to 5 mm in thickness, with no calcification at any spot. Microscopically the sections showed almost pure collagen, with only the smallest collections of lymphocytes and nothing to suggest tuberculosis. The left pleural cavity was also completely obliterated by old fibrous adhesions, and at the left base, between the lung and diaphragm, this fibrous tissue was 2 to 3 cm in thickness, being dense and practically cartilaginous in consistence. The right pleural cavity contained a liter of cloudy fluid, probably a terminal accumulation. The lungs showed two distinct types of lesions. There were a

large number of pulmonary infarcts — some quite fresh and others slightly older, none of them were very old, however. There were numerous pulmonary emboli to go with them, including a massive embolus, which apparently caused the sudden death. Also scattered irregularly throughout both lungs, but most marked in the right upper lobe, were areas of old completely organized pneumonia. It is quite clear that these were not infarcts, but it is impossible on the basis of the sections to guess how old the process was. There appeared to be nothing active about it in the terminal period, it might have been months or even years old.

Finally, there was a marked cirrhosis of the liver. This was the coarsely nodular type and, to my eye, did not resemble cardiac cirrhosis, which is so often seen in cases of adhesive pericarditis. It was probably a separate lesion of entirely different etiology. Another incidental finding, probably of no significance, was chronic interstitial pancreatitis of moderate severity.

DR KING And no tuberculosis?

DR MALLORY None anywhere

DR ALLAN G BRAILEY Do you think that the bloody pleural fluid was due to infarcts at various times?

DR MALLORY The fluid was found several years before the final entry, if I remember correctly. The old scars in the lung all look like those of organized pneumonia, not of infarcts. I think that is a distinction we can make with reasonable certainty because the scar of a healed infarct is rather characteristic.

DR KING Do these idiopathic processes usually produce as much fever? Have you had cases like this before with persistent temperature?

DR MALLORY I do not dare answer that

DR BLAND Did the pulmonary infarcts account for the peaks of temperature?

DR KING They might have, I suppose

DR MALLORY It is rather interesting that, despite the cirrhosis of the liver, the numerous pulmonary infarcts did not produce jaundice in the terminal period, as they commonly do with other types of cardiac disease.

DR BLAND Were the veins examined?

DR MALLORY There were thrombi in the leg veins

DR KING Was this a pneumococcal pneumonia?

DR MALLORY There was no acute pneumonia. I believe that all the fresh episodes were due to infarction.

CASE 32102

PRESENTATION OF CASE

A seventy-eight-year-old man entered the hospital complaining of abdominal pain.

During the few months before admission he had occasional bouts of intermittent lower abdominal

the wards essentially paralleled Dr Simeone's reasoning. Diverticulitis was considered the most probable diagnosis, and the sudden episode was interpreted as a perforation. An exploratory laparotomy was performed by Dr J G Scannell. He found a diffuse purulent peritonitis, most marked in the pelvis. The appendix was normal. A mass was found at the rectosigmoid junction that was thought to be inflammatory and secondary to a perforated diverticulum. A transverse colostomy was done, and the patient was put on the usual regime for peritonitis. His general condition steadily deteriorated, and he died on the fifth day after operation.

The post-mortem examination showed a severe diffuse peritonitis that involved all parts of the peritoneal cavity without any localized collection to suggest abscess formation. A mass could be felt at the junction of the sigmoid and rectum that constricted the bowel, reducing the lumen to a diameter

of 2 cm. On opening the bowel a characteristic ulcerative carcinoma was found, with a perforation in the center of the area of ulceration. The perforation was small, and no free fecal material was found in the peritoneal cavity. Although diverticula were present throughout the bowel none showed evidence of inflammation.

The other findings at autopsy were for the most part coincidental. There was massive collapse of the lower lobe of the right lung. The heart showed a hypertensive hypertrophy, and although the coronary arteries were sclerotic and narrowed, there was no evidence of infarction. The gall bladder was large and contained numerous large stones. The major portion of the prostate had been removed, and there was comparatively little regeneration.

Microscopical examination proved the tumor in the bowel to be a well differentiated adenocarcinoma. There were no implantations or metastases.

becomes about as common in occurrence in the older age groups as it is in the fifty-to-sixty group

Diverticulitis is more frequent among males than among females, but this point is of little help in differential diagnosis

Lack of blood in the stools is certainly in favor of diverticulitis, as opposed to carcinoma of the sigmoid. It is true, of course, that some patients with carcinoma do not have blood in the stools and that 10 to 20 per cent of those with diverticulitis do show this sign. Nevertheless, the lack of blood in the stools can be interpreted as strongly in favor of diverticulitis

A mass is felt more frequently with diverticulitis than with carcinoma. No definite statement is made that no mass was palpated, but it can be assumed that none was found. Absence of a mass, however, is not conclusive evidence against diverticulitis

Slight tenderness in both lower quadrants is consistent with diverticulitis. It is equally consistent, although less often elicited, with carcinoma complicated by penetration or perforation. Such a carcinoma, however, should have been demonstrated by obvious mucosal changes in the roentgenogram

The fever and leukocytosis suggest an inflammatory reaction. Although these signs favor diverticulitis, they do not exclude carcinoma, which, as already mentioned, may have an inflammatory reaction about it

Hypoproteinemia and hypochloremia are recorded as isolated occasions. These observations can be assumed to be accurate and are not extraordinary in an old man who has had chronic intestinal obstruction with recent vomiting. The patient may not actually have been as well nourished as he seemed

The roentgenographic finding of diverticula is strongly in favor of diverticulitis as the cause of the patient's symptoms. It does not exclude carcinoma, however, for cancer may coexist with diverticulitis and diverticulosis. The irregularity of the bowel wall is typical of diverticulitis. If we are justified in assuming that no abnormality was detected in the mucosa itself, this is strong evidence against carcinoma. The lack of spasm is against diverticulitis but does not rule it out. The degree to which the lumen was narrowed, if at all, is not stated. If there was little narrowing, the finding would favor diverticulitis

On weighing all the evidence, we find more in favor of diverticulitis than of carcinoma. The reference of pain about the rectum is more consistent with diverticulitis than with uncomplicated carcinoma. The final episode of generalized tenderness and boardlike spasm in the abdomen indicates a generalized peritonitis, which followed shortly after the administration of a barium enema. This is more readily explained on the basis of diverticulitis than on that of carcinoma. It may be

assumed that the manipulation or the pressure developed when unsuccessfully attempting to expel the enema caused perforation of a gangrenous diverticulum. This resulted in a spreading peritonitis. Such occurrences are rare but have been described. The same picture could have been produced by the rupture of an abscess about the area involved in the diverticulitis. This is suggested by the fact that no gas was found beneath the diaphragm by x-ray examination when the patient was examined in the standing position. Absence of demonstrable air beneath the diaphragm, however, does not rule out perforation of the bowel at the site of a diverticulitis. Perforation of a malignant lesion of the colon is not infrequent during proctoscopy or sigmoidoscopy, but I am not aware of such a complication following a barium enema.

The question arises whether perforation may have occurred in the bowel at a site other than that of the lesion itself. Rupture of the large intestine as the result of obstruction in the colon usually occurs in the cecum. Had this taken place in this patient, air beneath the diaphragm would have been expected and there should have been evidence of severer bowel obstruction beforehand than there apparently was

In summary, the patient's long history of constipation, the low abdominal pain and tenderness, the pain in the rectum, the mild fever and leukocytosis, the evidence of incomplete large-bowel obstruction by history and roentgenograph, the x-ray evidence of a partially obstructing lesion in the sigmoid with diverticula nearby and without obvious destruction of the mucosa and the absence of blood in the stools suggest a diagnosis of diverticulitis. The episode that led to emergency surgery was a spreading peritonitis as the result of perforation of an involved diverticulum

CLINICAL DIAGNOSES

Peritonitis from perforated viscus
Hypertension
Arteriosclerosis

DR SIMEONE'S DIAGNOSES

Diverticulitis of colon, with perforation and generalized peritonitis
Diverticulosis of colon

ANATOMICAL DIAGNOSES

Adenocarcinoma of rectosigmoid, with perforation.
General peritonitis
Operative wound transverse colostomy
Cardiac hypertrophy, hypertensive type
Arteriosclerosis of coronary arteries, moderate
Arteriosclerosis of aorta, severe
Pulmonary atelectasis
Diverticulosis of colon
Prostatectomy, old, transurethral

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Clinical discussion on

the wards essentially paralleled Dr. Simeone's reasoning. Diverticulitis was considered the most probable diagnosis, and the sudden episode was interpreted as a perforation. An exploratory laparotomy was performed by Dr. J. G. Scannell. He found a diffuse purulent peritonitis, most marked in the pelvis. The appendix was normal. A mass was found at the rectosigmoid junction that was thought to be inflammatory and secondary to a perforated diverticulum. A transverse colostomy was done, and the patient was put on the usual regime for peritonitis. His general condition steadily deteriorated, and he died on the fifth day after operation.

The post-mortem examination showed a severe diffuse peritonitis that involved all parts of the peritoneal cavity without any localized collection to suggest abscess formation. A mass could be felt at the junction of the sigmoid and rectum that constricted the bowel, reducing the lumen to a diameter

of 2 cm. On opening the bowel a characteristic ulcerative carcinoma was found, with a perforation in the center of the area of ulceration. The perforation was small, and no free fecal material was found in the peritoneal cavity. Although diverticula were present throughout the bowel none showed evidence of inflammation.

The other findings at autopsy were for the most part coincidental. There was massive collapse of the lower lobe of the right lung. The heart showed a hypertensive hypertrophy, and although the coronary arteries were sclerotic and narrowed, there was no evidence of infarction. The gall bladder was large and contained numerous large stones. The major portion of the prostate had been removed, and there was comparatively little regeneration.

Microscopical examination proved the tumor in the bowel to be a well differentiated adenocarcinoma. There were no implantations or metastases.

CARDIAC MURMURS

A LETTER published elsewhere in this issue of the *Journal* criticizes the stand taken in a recent paper* regarding the significance of apical systolic murmurs. Undoubtedly, in the interpretation of heart murmurs the pendulum swung from one extreme to the other thirty years ago, when James Mackenzie urged the medical profession to disregard auscultatory cardiac findings, provided there was an adequate state of the circulatory function. That advice served a useful purpose—it did help win World War I by allowing many able-bodied men with heart murmurs to serve in the British forces. But the interpretation was too literal, and for many years British medicine suffered from its indiscriminate acceptance. One cardiologist states that

as long as ten years after the end of World War I he found cases of clear-cut and clinically significant aortic stenosis on the wards of Thomas Lewis that had been undiagnosed because of the scorn of stethoscopic findings. In other words, the pendulum was still at its extreme. During the last two decades, however, it has become the experience of most cardiologists who went through the earlier period that this casual attitude is not only unscientific but actually dangerous. There are three reasons for this.

In the first place, valvular disease produces a strain on the heart muscle, at times it is slight or moderate, but sometimes it is considerable, even though cardiac function and reserve may, for the moment, be adequate. In almost all cases trouble looms up ahead, and the more careful the patient is to avoid unnecessary strain, the longer is the postponement of trouble. Of course, the development of a crippling neurosis or valetudinarianism should be avoided, but so too should the unnecessary early induction of acute pulmonary edema by a disregard of the considerable strain resulting from a previously symptomless but easily diagnosed aortic stenosis. There is a happy mean in the conduct of such a person's life.

In the second place, a healthy young person with chronic valvular disease is a candidate for recurrent rheumatic fever if exposed to infection by the hemolytic streptococcus, as experience in World War II has so clearly demonstrated. Such a person obviously deserves some protection.

Finally, it is true that one of the most infallible guides to the presence of active rheumatic infection in a doubtful case is the development of a heart murmur *under observation*, especially the controversial apical systolic murmur not explained by anemia or other factors but due to left ventricular dilatation secondary to acute rheumatic myocarditis.

Any moderate or loud apical or aortic systolic murmur in a person *at rest* is best regarded as abnormal unless proved to the contrary. The cause may, of course, be extracardiac, but it should be looked for and diagnosed, whether intracardiac or extracardiac.

No brief should be held for the exaggeration of

*Wolfson, I. N. Cholecal and laboratory studies of 91 workers with apical systolic murmurs. *New Eng J Med* 233:757-761, 1945.

the importance of heart murmurs, in fact their neglect is the lesser of the two evils, but it is possible with care and experience to avoid both extreme points of view and to develop the use of the stethoscope as an extremely valuable medical tool in the diagnosis of heart disease

SCHOOL-HEALTH POLICIES

School health in its various aspects and the impact of school medical services on health education have received nearly their share of attention in the last decade. It is up to those who are interested in it, however, to see that school health does not fall too far into the category of Mark Twain's New England weather, about which so many have talked and so few have attempted any practical reforms.

The Strayer Report on the Boston Public Schools, published in 1944 in its various volumes, contained recommendations on school lunches and on physical and health education that were considered by a committee of the Boston Health League and, in the main, favorably reported on. The Division of Child Hygiene of the Massachusetts Department of Public Health has developed excellent procedures to be used as guides in the towns and cities of Massachusetts outside Boston, studies have been made jointly by the State Department of Health and the State Department of Education, and many other wise pronouncements the Nation over are available for those who wish to profit by them.

If there is any real reason why the country's schools do not have and do not follow the best and most progressive health policies, it is because of a public that is bent on other forms of whoopee or because of the inertia of municipal politics when applied to academic problems.

The American Academy of Pediatrics interested itself in the problem of school health soon after its organization in 1931 and formed a committee to study the subject. It has published various reports including a statement "Suggested School-Health Policies" produced jointly with the Child Hygiene Section of the American Public Health Association. A revision of this report has been currently made public by the National Conference for Co-operation

in Health Education,* and the pamphlet includes about all the advice that can be given to anyone interested in establishing school-health policies in any locality.

Particularly important with respect to these modern school-health policies is the necessity of raising school health and health education to the position of dignity and importance that belongs to them. Teachers should be prepared at teachers' colleges to assume their share of the health program, school nursing should be on a career level, the branch of public health that deals with school health and health education should be expected to furnish careers for an adequate number of trained physicians. The school should participate in community health education, and conversely, the community should interest itself in the health policies of its schools. Inside the school, the health council should be a representative body including students and parents, and this council should co-ordinate with the central school-health council and the community health council.

As with so many of life's obstacles, the problem lies not so much in finding a way to follow as in finding the will to follow the way.

MASSACHUSETTS MEDICAL SOCIETY

REVIEW LECTURE COURSE

The following is the detailed program of the Review Lecture Course from March 18 to April 15, inclusive.

March 18 GASTROINTESTINAL DISEASES Chairmen Sara M. Jordan and Franklin W. White

5:00-5:30 Diagnosis of Cancer of the Digestive Tract
Franz J. Ingelfinger, assistant professor of medicine, Boston University School of Medicine, gastroenterologist, Massachusetts Memorial Hospitals

5:30-6:00 Functional Diseases of the Digestive Tract
Sara M. Jordan, chief Department of Gastroenterology, Lahey Clinic, physician, New England Baptist and Deaconess hospitals

6:00-6:30 Ulcerative Colitis
Isaac R. Jankelson, assistant professor of medicine, Tufts College Medical School, junior visiting physician, Boston City Hospital

7:30-8:00 Epidemiology of Amebiasis and the Dysenteries
Vlado A. Getting, Commissioner of Public Health, Commonwealth of Massachusetts

8:00-8:30 Diseases of the Small Intestine
Katherine S. Andrews, surgeon, New England Hospital for Women and Children

8:30-9:00 Some Proctologic Problems
E. Parker Hayden, assistant in surgery, Harvard Medical School, assistant surgeon, Massachusetts General Hospital

*The American Academy of Pediatrics and the American Public Health Association. *Suggested School Health Policies*. Second edition revised 57 pp. 1945.

March 20 DISEASES OF THE LIVER, GALL BLADDER AND PANCREAS *Chairmen* Chester M Jones and Leland S McKittick

3 00-3 45 *Epidemiology of Hepatitis* Roy F Feemster director, Division of Local Health Administration, Massachusetts Department of Public Health

3 45-4 30 *Chronic Hepatic Disorders* Chester M Jones clinical professor of medicine, Harvard Medical School, physician, Massachusetts General Hospital

4 30-5 15 *Surgery of the Biliary Tract* Charles G Mixer surgeon-in-chief, Beth Israel Hospital

5 45-6 30 *Physiotherapy in the Treatment of Arthritis* Arthur Watkins chief of physical medicine, Massachusetts General Hospital, associate in medicine, Harvard Medical School

DISEASES OF THE BONES AND JOINTS *Chairmen* Frank R Ober and William A Rogers

7 30-8 15 *Lame Backs* William A Rogers instructor in orthopedic surgery, Harvard Medical School, visiting orthopedic surgeon, Massachusetts General Hospital

8 15-9 00 *Lame Shoulders* Frank R Ober John B and Buckminster Brown Clinical Professor of Orthopedic

The Journal lacks copies of the December 6, 1945 and January 3, 1946, issues. If any subscribers who do not bind their copies have the above-mentioned issues on hand, the Journal will gladly pay 15 cents for each copy left at or mailed to its office (8 Fenway, Boston 15).

5 15-6 00 *Diagnosis and Treatment of Carcinoma of the Pancreas* Richard B Cattell surgeon, Lahey Clinic, surgeon, New England Deaconess and Baptist hospitals

March 25 SURGERY *Chairmen* Edward D Churchill and John W Spellman

5 00-5 30 *Progress Report* F D Moore instructor in surgery, Harvard Medical School, assistant in surgery, Massachusetts General Hospital

5 30-6 00 *Military Surgery* E D Churchill John Homan Professor of Surgery, Harvard Medical School, chief of West Surgical Service, Massachusetts General Hospital

6 00-6 30 *Shock and Resuscitation* J E Dunphy associate in surgery, Harvard Medical School, senior associate in surgery, Peter Bent Brigham Hospital, visiting surgeon, St Elizabeth's Hospital

7 30-8 15 *Choice of the Anesthetic Agent* Morris J Nicholson anesthesiologist, Lahey Clinic and New England Baptist and Deaconess hospitals

8 15-9 00 *Head Injury* Donald Munro associate professor of neurosurgery, Boston University School of Medicine, assistant professor of neurological surgery, Harvard Medical School, surgeon-in-chief and head of Department of Neurosurgery, Boston City Hospital

March 27. SURGERY *Chairmen* Edward D Churchill and John W Spellman

3 00-3 45 *Thermal Burns* Charles C Lund assistant professor of surgery, Harvard Medical School, visiting surgeon, Boston City Hospital

3 45-4 30 *Phlebitis, Thrombosis and Embolism* Claude E Welch assistant in surgery, Harvard Medical School, assistant visiting surgeon, Massachusetts General Hospital

ARTHRITIS *Chairmen* Marian W Ropes and Howard K Thompson

4 30-5 15 *Problems in the Treatment of Various Types of Chronic Arthritis* Nathan Sidel chief of Arthritis Clinic, Beth Israel Hospital, assistant visiting physician, Boston City Hospital, assistant professor of medicine, Tufts College Medical School

5 15-6 00 *Newer Concepts in the Management of Rheumatoid Arthritis With Special Reference to Gold Salts* Theodore Bayles visiting physician, Robert Breck Brigham Hospital, junior associate in medicine, Peter Bent Brigham Hospital

April 1 ARTHRITIS *Chairmen* Marian W Ropes and Howard K Thompson

5 00-5 45 *Orthopedic Care of the Chronic Arthritis* John Kuhns instructor in orthopedic surgery, Harvard Medical School, visiting orthopedic surgeon, Robert Breck Brigham and Infants' hospitals

Surgery, Harvard Medical School, orthopedic surgeon, Peter Bent Brigham Hospital, chief of Orthopedic Department, Children's Hospital

April 3 FRACTURES *Chairmen* Frank R Ober and William A Rogers

3 00-3 45 *Colles Fracture* Henry C Marble assistant in surgery, Harvard Medical School, visiting surgeon, Massachusetts General Hospital, surgeon-in-chief, Chelsea Memorial Hospital

3 45-4 30 *Fractures of the Elbow* Carroll B Larson assistant in orthopedic surgery, Massachusetts General Hospital, assistant in surgery, Harvard Medical School

NEUROSURGERY OF CHILDHOOD *Chairmen* Franc D Ingraham and James B Campbell

4 30-6 00 *Congenital Anomalies, Injuries, Infections, Intracranial and Intraspinal Tumors, Jacksonian Epilepsy, and Lead Encephalitis* Franc D Ingraham surgeon-in-chief, Children's Hospital, assistant professor of surgery, Harvard Medical School James B Campbell junior attending surgeon in neurosurgery, Children's Hospital, assistant in surgery, Harvard Medical School

April 8 KIDNEY AND GENITOURINARY DISEASES *Chairmen* Laurence B Ellis and James P O'Hare

5 00-6 30 *Glomerular Nephritis and Nephrosis* Progress in etiology, pathology, physiology and clinical management. Stanley E Bradley instructor in medicine, Boston University School of Medicine, assistant physician, Evans Memorial, Massachusetts Memorial Hospitals W Richard Ohler assistant professor of medicine, Harvard Medical School, chief, Second Medical Service, Boston City Hospital

7 30-8 15 *Urinary-Tract Infections* E Granville Crabtree urologist, New England Baptist, Newton and Beth Israel hospitals

8 15-9 00 *The Female Bladder* Samuel N Vose professor of genitourinary surgery, Boston University School of Medicine, urologist, Massachusetts Memorial Hospitals

April 10 PEDIATRICS *Chairmen* James M Baty and Joseph Garland

3 00-3 45 *Care and Feeding of Newborn* Stewart H Clifford pediatrician, Boston Lyng-in Hospital, assistant visiting physician, Children's Hospital

recent requirements a fraud and a deceit that would subject the offender to disciplinary action

The court found that the delegation by the Legislature to the Regents of the authority to make such rules was proper and that, in the absence of action on the subject by the Legislature, the Regents could make the rule in question — (*Buhl v University of State of New York*, 52 N Y S [2d] 511, Dec 29, 1944)

CORRESPONDENCE

CARDIAC MURMURS

To the Editor In view of the enormous amount of unnecessary invalidism and psychic trauma caused by physicians who are unable to evaluate systolic murmurs, it seems unfortunate that Wolfson's communication, "Clinical and Laboratory Studies of Ninety-One Workers with Apical Systolic Murmurs," which appeared in the December 20, 1945, issue of the *Journal*, did not elicit at least a modifying editorial comment.

The author states, "A murmur was considered to be associated with a cardiovascular abnormality when the patient had a history of rheumatic fever [a doubtfully valid assumption], hypertension, roentgenologic evidence of cardiac enlargement, an abnormal electrocardiogram, or other disease that might be expected to produce a murmur [again, a doubtful assumption unless one considers the hemic murmur of anemia to be evidence of a cardiovascular abnormality]"

The author also states "In the youngest age group, below twenty-five, a history of rheumatic fever was obtainable in more than half the cases. From this it may be concluded that an apical systolic murmur in a young patient is likely to be associated with rheumatic fever." On going back to the author's criteria for a past history of rheumatic fever, however, one finds the following statement "Careful inquiries were made for a past history of rheumatic infection, and this was said to be positive only when it included at least one of the following: an illness characterized by swollen, painful, tender joints, an illness of several weeks' duration, diagnosed at the time by the attending physician as rheumatic fever, *prolonged bed rest recommended by a physician because of the discovery of a heart murmur* [italics mine], and St. Vitus's dance." It seems most unfortunate that the author accepts "prolonged bed rest recommended by a physician because of the discovery of a heart murmur" as evidence of rheumatic infection. I believe that this assumption is entirely unjustified and, as often as not, represents an incorrect diagnosis on the part of the attending physician.

Judging from personal experience in a small outpatient cardiac clinic (Cambridge Hospital) on the medical ward service of a large city hospital (Boston City Hospital) and in the internists' department at an induction center (First Service Command), I believe that the finding of an apical systolic murmur as the sole sign of a cardiac disorder in a person under twenty-five without hypertension, hyperthyroidism, tachycardia, fever, anemia or a clear-cut history of rheumatic fever is better ignored than studied.

This I believe, is still true even in the presence of organic heart disease. An apical systolic murmur in the absence of cardiac enlargement (by x-ray) or diminished exercise tolerance is no contraindication to normal physical activity, including strenuous sports, and should never be the reason for putting a person to bed for weeks or months.

The incidence of cardiac neuroses and unnecessary cardiac invalidism in young people with systolic murmurs is a most unfavorable commentary on the practicing physicians in this country. The stethoscope is a double-edged sword, and I still agree with MacKenzie that the physician would do well to throw away his stethoscope while evaluating cardiac murmurs.

DUDLEY MERRILL, M.D.

MEDICOLEGAL ABSTRACT

Regulation of Practice by Government Qualifications to Practice A man who had taken out life insurance from the defendant company died. The plaintiff was his beneficiary. The policy contained a clause which provided that, if the insured had received medical or surgical treatment within two years prior to his application for insurance and had not disclosed this fact on the application, the policy would be voidable. The deceased did receive treatments from a chiropractor within the period and did not disclose this fact.

The beneficiary brought suit to recover the proceeds of the policy, which the company refused to pay on the grounds that the treatment by the chiropractor was undisclosed medical or surgical treatment rendering the policy voidable. The trial court refused to direct a verdict for the defendant, and the defendant appealed. In reversing the judgment, the Supreme Court of New Jersey said that the Legislature had regulated the practice of chiropractic under "an act to regulate the practice of medicine and surgery" and that it was within the power of the Legislature to so classify it — (*Kahn v Metropolitan Life Insurance Company*, 41 Atl [2d] 329, March 1, 1945, New Jersey)

In New York, however, possession of a mere license to practice podiatry or chiropody, without more, does not confer on the licensee the right to call himself "doctor."

Originally the educational requirements to practice podiatry and chiropody were one year of college and three years of professional training. Subsequently they were increased, and graduates were admitted to the degree of doctor of podiatry or chiropody. This placed those who were licensed under the original requirements at a disadvantage, and they sought to call themselves "doctor" too. They therefore brought an action seeking to have rescinded a rule promulgated by the Regents of the State University declaring the use of the title "doctor" by those who had not fulfilled the more

NOTICES

ANNOUNCEMENTS

Dr William W Babson announces his return to the practice of surgery at 79 Prospect Street, Gloucester

Dr James R Corkery, having returned from military service, has resumed practice at 6 Hancock Street, Everett

Dr Sidney Derow, having been released from active duty with the United States Navy, has resumed his practice at 925 Centre Street, Newton Centre

Dr Clifford C Franseen announces his return from military service and the reopening of his offices at 1180 Beacon Street, Brookline, for the practice of surgery

Dr Irvin G Gahm announces his return from military service and resumption of practice at 414 Walnut Street, Newtonville

Dr Stuart N Gardner, having returned from service with the United States Navy, announces the reopening of his office at 24 Chestnut Street, Salem, for the practice of internal medicine

Dr A Gordon Gauld announces the reopening of his office for the practice of obstetrics and gynecology at 330 Dartmouth Street, Boston

Dr Richard J Gorman, having returned from service with the United States Navy, announces the opening of his office at 628 Centre Street, Jamaica Plain, for the general practice of medicine

Dr Lyman H Hoyt, having returned from service in the Medical Corps of the United States Navy, has resumed his practice at 51 Bay State Road, Boston

Dr Samuel W Joel announces his return from military service and the reopening of his office for the practice of psychiatry and neurology at 510 Commonwealth Avenue, Boston

Dr William E Ladd announces the removal of his office from the Children's Hospital to 330 Dartmouth Street, Boston

Dr William N Lanigan, recently released from military service, announces the reopening of his office at 187 Main Street, Medford, for the practice of orthopedic surgery

Dr Charles C Lund announces the removal of his office from 319 Longwood Avenue to 20 Gloucester Street, Boston

Dr Charles J McCarthy has been released from military service and has resumed the practice of medicine at 466 Medford Street, Somerville

Dr John D Shinberg, having returned from the armed services, announces the reopening of his office at 54 Merrimack Street, Haverhill

MEDICAL LIBRARY ASSOCIATION

The Medical Library Association will hold its postwar convention at the Yale Medical Library, New Haven, Connecticut, on March 25, 26 and 27. The program will include papers on the history of medicine in Connecticut by Drs Herbert Thoms and Harold S Burr and on the libraries of Yale University by Mr J T Babb, Dr John F Fulton and others. Dr Sanford V Larkey will speak on his experiences as medical historian of the European Theater. Miss Ethel Wigmore, of the National Institute for Medical Research, will discuss British and Continental medical libraries. There will also be reports on the organization of the Army Medical Library by members of its staff and general discussions on interlibrary and international co-operation. The training necessary for medical librarianship is the subject chosen for the presidential address by Miss Mary Louise Marshall. The speaker at the annual banquet will be Professor C-E A Winslow. Headquarters will be at the Hotel Taft. Further details may be obtained from the secretary—Miss Frida Pfeifle, 2000 Medical Arts Building, Minneapolis, Minnesota.

TRAUMA OF THE LOWER URINARY TRACT*

A Roentgenologic Study

H STEPHEN WEENS M.D. † J HAROLD NEWMAN M.D. ‡ AND THOMAS J FLORENCE M.D. §

ATLANTA, GEORGIA

INJURIES of the bladder and posterior urethra constitute surgical emergencies. Appropriate therapy instituted early, usually gives gratifying results, but delay in treatment causes a sharp increase in the morbidity and mortality. It is therefore important that there be available safe, simple and reliable diagnostic procedures.

The clinical history and physical examination may provide sufficient information to establish a diagnosis, but oftener they serve only to focus attention on the lower urinary tract without permitting a definite conclusion concerning the exact site and extent of the injury. The urinalysis may even be deceptive. Intraperitoneal rupture of the bladder can exist in the presence of grossly clear urine¹ and conversely, hematuria may occur in the absence of significant injury to the urinary tract.

Diagnostic procedures that utilize a catheter introduce a new element of trauma in urethral injuries. Urinary flow after introduction of a catheter does not exclude vesical rupture, since urine may be drained from the peritoneal cavity. For the same reason, recovery of measured quantities of fluid introduced into the bladder through a catheter does not permit exclusion of vesical injuries.

The value of cystoscopy in trauma of the lower urinary tract is the subject of much controversy. It constitutes a comparatively major procedure that may aggravate the injury and often fails to establish a diagnosis. The demonstration of injury to the urinary bladder by the intravesical injection of air has certain disadvantages. In the presence of pelvic trauma it is usually difficult to obtain the necessary roentgenograms with the patient in the upright and recumbent positions. Furthermore, the danger of air embolism cannot be lightly dismissed.²

Most recent authors³⁻⁵ agree that urethrography

and cystography with a radio-opaque medium represent the most satisfactory diagnostic procedures available. With these methods one should be able to demonstrate any injury that interrupts the continuity of the urethra or bladder. This may be accomplished with a minimum of manipulation, pain and trauma. Although much emphasis has been placed in the recent literature on the value of these diagnostic procedures, little attention has been given to their correct interpretation. Culp⁴ in an analysis of a large series of cases of ruptured urethra and bladder, states that retrograde cystograms showed extravasation in every case in which they were employed and that the chief difficulty encountered was failure to interpret accurately the extent of extravasation. Lewis⁵ cites a case of intraperitoneal rupture of the bladder in which cystography was performed but because of failure of interpretation the diagnosis was not made.

For these reasons it was thought worth while to report 7 cases of trauma of the lower urinary tract with emphasis on the salient roentgenologic features.

CASE 1. L. L. H. (A-57673) a 24-year-old woman was admitted 48 hours after having been injured in an automobile accident. She had not voided or had a desire to do so since the time of the injury. Shortly before admission a local physician had catheterized the patient and obtained 2000 cc of bloody urine. On examination the patient was markedly distended and had the classic signs of generalized peritonitis. An intravenous pyelogram demonstrated normal urinary passages, including a normal bladder (Fig. 1). A Foley catheter was introduced, and 200 cc of bloody urine was obtained. Since a bladder injury was still suspected, a retrograde cystogram was made. It revealed extensive intraperitoneal extravasation (Fig. 2). Therapy consisted of drainage of the bladder with a Foley catheter, chemotherapy, parenteral nutrition and intestinal decompression with a Miller-Abbott tube. The patient made an uneventful recovery and was discharged on the 19th hospital day.

Comment. This case illustrates the fact that recovery of large volumes of urine after catheterization does not exclude vesical injury. Apparently the large amount of urine obtained by catheterization was drained chiefly from the peritoneal cavity.

CASE 2. T. J., (A-85633), a 43-year-old man, was admitted in an intoxicated, disoriented condition shortly after an automobile accident. X-ray examination showed dislocation of the left sacroiliac joint and fractures of several ribs. The

left humerus and both pubic bones. The patient was unable to void, and 100 cc of grossly bloody urine was obtained by catheterization. Two hundred and fifty cubic centimeters of sterile water was injected into the bladder, and the same amount was recovered by aspiration. Since signs of peritonitis developed, an intravenous pyelogram was performed. This revealed no traumatic changes in the upper urinary tract. The urinary bladder was not visualized. A subsequent retrograde cystogram disclosed intraperitoneal extravasation (Fig 3). On exploratory laparotomy a stellate laceration

to No 30 Fr with graduated curved Van Buren sounds. A No 28 Fr Stern-McCarthy electrotome was introduced, and inspection preliminary to prostatic resection was performed. The field was obscured by blood, and a diminished quantity of the irrigating fluid seemed to return. The bladder could not be sufficiently distended to visualize its interior satisfactorily. As the anesthetic reached the level of the umbilicus, the patient began to complain of epigastric pain. Rupture of the bladder was suspected, and a cystogram was performed. It revealed intraperitoneal extravasation (Fig 4).

FIGURE 1 Case 1

This is a normal excretory cystogram in a patient with intraperitoneal rupture of the urinary bladder

of the bladder dome 2 cm. in width was found and repaired. The peritoneum was closed, and a cystostomy was performed. The patient died of peritonitis on the 4th postoperative day.

Comment. This case demonstrates that injection and recovery of measured quantities of fluid is not a reliable procedure in the detection of rupture of the bladder.

CASE 3 G W M (A-110617), a 69-year-old man was admitted with acute urinary retention resulting from fibrous contracture of the vesical neck, which was relieved by inserting a small urethral catheter. He was given a spinal anesthetic on the 6th hospital day, and the urethra was dilated

Exploratory laparotomy disclosed a small rent in the bladder dome. This was sutured, and cystostomy was performed. Recovery was uneventful.

Comment. Even though cystoscopy was facilitated by spinal anesthesia in this case, it was impossible to visualize the rent in the bladder.

CASE 4 W J (A-110131) a 23-year-old woman, was admitted shortly after an automobile accident in which she sustained fractures of the left femur, the right clavicle and both pubic bones. A specimen of urine obtained by catheterization was grossly bloody. After insertion of a Foley

catheter a cystogram was made. This disclosed extensive diffusion of the contrast medium into the pelvic tissues (Fig 5). Exploratory laparotomy revealed no injury of any intraperitoneal structure. After closure of the peritoneum the retroperitoneal space was investigated and laceration of the bladder wall 3 cm in length was found. Suprapubic cystos-

CASE 5 V V (A-115043), a 40-year-old woman, was admitted after an automobile accident, she was suffering from dyspnea and complaining of pain on respiration. Roentgenologic examination disclosed multiple rib fractures and emphysema of the chest wall. There were bilateral fractures of the pubic rami and a linear fracture of the sacrum. Equivo-

Exploratory laparotomy disclosed a small rent in the bladder dome. This was sutured, and cystostomy was performed. Recovery was uneventful.

Comment Even though cystoscopy was facilitated by spinal anesthesia in this case, it was impossible to visualize the rent in the bladder.

CASE 4 W J (A-110131) a 25-year-old woman was admitted shortly after an automobile accident in which she sustained fractures of the left femur, the right clavicle and both pubic bones. A specimen of urine obtained by catheterization was grossly bloody. After insertion of a Foley

intrapertoneal injury was present. After closure of the peritoneum a laceration of the anterior bladder wall 5 cm in length was found. Treatment consisted of suprapubic cystos-

tomized with fractures of both pubic bones and the left wing of the sacrum, sustained in an automobile accident. Shortly after admission he voided 500 cc of bloody urine with con-

FIGURE 5 Case 4

This retrograde cystogram shows the findings in a case of extraperitoneal rupture of the urinary bladder. There is extensive diffusion of the contrast medium into the pelvic tissues producing a sunburst-like appearance. Note the absence of filling defects caused by the intestinal loops. There is no pooling of the contrast medium in the dependent portions of the peritoneal cavity, such as occurs in intraperitoneal rupture.

tomy with drainage of the space of Retzius. The patient made a satisfactory recovery.

Comment: In this case laparotomy confirmed the roent-

genetic diagnosis of an exclusively extraperitoneal bladder injury. Examination revealed no tumefaction in the hypogastrium, perineum or rectum. Retrograde urethro-

cystograms showed extravasation in the region of the bladder

FIGURE 6 Case 5

This is a retrograde cystogram in another case of extraperitoneal extravasation. The contrast medium has penetrated into the tissues of the pelvic floor and pre-sacral space. Note the pyriform contour and displacement of the urinary bladder.

genologic diagnosis of an exclusively extraperitoneal bladder injury.

CASE 6 J. W. (A-111627), a 38-year-old man, was ad-

mitted with fractures of both pubic bones and the left wing of the sacrum, sustained in an automobile accident. Shortly after admission he voided 500 cc of bloody urine with con-

neck (Fig. 7). The bladder had a smooth, elongated pyriform contour. The initial therapy consisted only of drainage with a Foley catheter and chemotherapy. A septic course ensued

FIGURE 3 Case 2

This retrograde cystogram shows intraperitoneal extravasation, with accumulation of the contrast medium between the intestinal loops (a) Note the contrast medium in the paracolic recess (b)

FIGURE 4 Case 3

This is another retrograde cystogram showing intraperitoneal extravasation. Note the characteristic filling defects in the extravasated contrast medium produced by the intestinal loops

frequently distended with gas cast characteristic filling defects in the extravasated contrast medium. These defects are round or cylindrical and are recognized without difficulty (Figs 2, 3 and 4). A second and most significant roentgenologic sign is produced by the accumulation of contrast medium as a band-like or linear density along the peritoneal reflection of the flanks (paracolic recesses) (Figs 2 and

FIGURE 8 Case 7

This is a normal retrograde cystogram after the injection of contrast medium through the catheter

3) The radio-opaque medium, even in a low concentration or in small amounts, is easily visible because of the sharp contrast furnished by the subperitoneal layer of fat. Likewise, the haustral markings of the colon and loops of small intestine may produce a scalloped impression along the inner aspect of these bands of increased density (Figs 2 and 3). For these reasons, film studies made in cases of suspected intraperitoneal rupture should include the entire abdomen and its walls.

In contrast, posterior urethral and extraperitoneal vesical ruptures are characterized by more or less diffuse penetration of the contrast medium into the tissues of the pelvic floor and prevesical space. In massive extravasations the medium may assume a sunburstlike appearance (Fig 5). Smaller extravasations are represented by streaks and feathery bands extending from the urinary bladder toward the surrounding soft-tissue structures (Figs 6 and 7). The urinary bladder is frequently deformed in extraperitoneal extravasations. It may assume an elongated pear-shaped appearance or may be dislocated in any direction (Fig 7). Such a deformity

should be considered only as a presumptive sign, since similar changes in the configuration of the bladder may be caused by large pelvic hematomas and abscesses.

The combination of intraperitoneal and extraperitoneal rupture of the urinary bladder was not encountered in this small series. The roentgenologic features of both conditions may be expected in such a combination. The signs of intraperitoneal rupture are likely to be predominant, since the peritoneal cavity probably offers less resistance to extravasating fluids than do the paravesical tissue spaces.

It should be emphasized that intravenous pyelography may produce a seemingly satisfactory

FIGURE 9 Case 7

This is a retrograde urethrocytogram in the same patient as shown in Figure 8. Note the extensive extravasation in the region of the posterior urethra

cystogram but is highly unreliable in the diagnosis of trauma of the lower urinary tract. It may fail to demonstrate extravasation because of insufficient density of the medium or because the bladder is not filled under sufficient pressure to produce leakage. This fact is illustrated by Case 1, in which the excretory cystogram showed a well filled bladder with the contrast medium in good concentration (Fig 1) but failed to demonstrate the extravasation that was subsequently discovered by a retrograde cystogram (Fig 2). Suprapubic pressure or straining by the patient may make it possible to demonstrate extravasation in cases in which an adequate excretory urogram has been obtained.

It is also important to note that normal cystograms may be obtained in urethral injuries when a catheter has been passed over the urethral rent into

but responded to suprapubic cystostomy and free drainage of the extravasated area

Comment In this case it was impossible to determine from the urethrocytogram whether the injury involved the bladder base or the prostatic urethra. An intraperitoneal rupture, however, could be excluded with certainty

CASE 7 C D (A-107554), a 36-year-old man, was admitted shortly after an automobile accident. X-ray examination disclosed fractures of both pubic bones. Because of difficult urination and gross hematuria, a catheter was intro-

duced into the bladder and a cystogram was made. In females, a catheter is preferable, since it may be introduced with ease and facilitates the injection of the contrast medium. Vaginal palpation with the catheter in place usually permits adequate examination of the urethra.

The volume of contrast medium* introduced should be individualized. A preliminary roent-

FIGURE 7 Case 6

This is a retrograde cystogram in a case of extraperitoneal extravasation following trauma of the posterior urethra or bladder neck. Note the elongated pyriform contour of the bladder.

duced into the bladder and a cystogram was made. The bladder had a normal contour, and no extravasation was demonstrated (Fig 8). The catheter was left in place but accidentally came out after 2 days. At that time retrograde urethrocytograms were obtained, which demonstrated extravasation of the contrast medium in the region of the posterior urethra (Fig 9). Perineal and rectal palpation failed to reveal evidence of extravasation at any time. The catheter was reinserted, and recovery ensued without further treatment.

Comment This case illustrates the fact that a cystogram performed after the introduction of a catheter into the bladder may fail to demonstrate an injury of the posterior urethra.

DISCUSSION

The technic of urethrocytography and the appearance of the normal urethrocytogram have been described by several authors^{6, 7} and will not be discussed herein. Various mechanical devices have been advocated for these procedures, and they are undoubtedly of high value. Nevertheless, adequate studies may be obtained without special instruments. An Asepto syringe suffices to introduce the contrast medium. In males, injection of the contrast medium through the urethra permits adequate

visualization of the entire urethra and bladder. In females, a catheter is preferable, since it may be introduced with ease and facilitates the injection of the contrast medium. Vaginal palpation with the catheter in place usually permits adequate examination of the urethra.

The roentgenologic diagnosis of rupture of the bladder and posterior urethra depends on the demonstration of extravasated contrast medium. Although the exact site of leakage is often obscured, it is possible by the pattern and distribution of the contrast medium to distinguish posterior urethral and extraperitoneal vesical injuries from those occurring on the peritoneal surface of the bladder.

In intraperitoneal rupture of the bladder, the opaque medium has a tendency to accumulate and penetrate into the more dependent portions of the pelvic peritoneal cavity when the patient assumes a supine position. The intestinal loops, which are

*In these studies a 20 per cent solution of Skiodan was used.

episodes of meningococcal meningitis separated by an interval of fourteen months, during which several infections of the upper respiratory tract and two severe attacks of tonsillitis occurred. Some doubt as to the source of the new infection was raised by this author, however, since at the time of his second attack there were several other cases of the disease in the area where the patient lived. Only 1 case in which subacute bacterial endocarditis due to *N meningitidis* may have been the site of origin of a recurrent attack of meningococcal meningitis has been reported in the literature (Lemierre, Laporte, Reilly and Laplane⁹). This patient had two attacks, preceded by bacteremia, one hundred and nine days apart. In the interval, he was apparently completely well. He recovered from the second episode, returned to work on a farm and was in apparent good health until seventeen months later, when he died shortly after having developed a hemiplegia. Post-mortem examination revealed an endocarditis of the aortic valve, with new and old vegetations, and a recent septal infarct of the brain.

The purpose of reporting the case presented below is to describe a true recurrence of meningococcal meningitis in a patient who was in the nephrotic phase of chronic diffuse glomerulonephritis. This patient had two episodes of meningitis and one of lobar pneumonia within a period of sixteen months. The possible relation of the nephrosis to the obviously decreased resistance to bacterial disease is an interesting subject for speculation, since the nephrotic state resulted from a chronic glomerulonephritis and was not of the so-called "lipoid" variety, in which great susceptibility to infection, particularly by a pneumococcus, is the rule.

CASE REPORT

C. C., a 22-year-old, unmarried woman, was admitted to the Haynes Memorial Hospital on November 14, 1944, with a diagnosis of meningitis. The family history was irrelevant. In 1941, generalized edema and "cloudy" urine had developed after a sore throat. A diagnosis of diffuse glomerulonephritis was made at that time, and the patient remained under medical observation for the next 3½ years, during which time she had varying degrees of edema, headache and hematuria but no hypertension. On March 26, 1944, she was admitted to the Newton Hospital because of pain in the fingers, nausea, vomiting, malaise, shaking chills, severe pain in the lower back and hips and transient periods of delirium of 24 hours' duration.

The temperature on this admission was 102°F, the pulse 100, the respirations 30, and the blood pressure 132/90. The skin was covered with petechiae, all the deep reflexes were hyperactive, the neck was stiff, and the Kernig and Brudzinski signs were strongly positive. Lumbar puncture revealed the spinal fluid to be under increased pressure and to contain 2400 cells, of a type not stated. The protein and glucose levels were 300 mg and 57 mg per 100 cc, respectively. A gram stain of the spinal fluid revealed many gram-negative diplococci in pairs. A blood culture was positive for meningococci. Treatment with sulfadiazine, instituted shortly after admission, resulted in a rapid fall in the temperature and clearing of the signs of meningeal infection, and the patient was discharged completely cured 37 days after admission.

She remained in a fair state of health, with recurring edema of the face and ankles, occasional slight headaches and per-

sistent anemia, hematuria and albuminuria, for the next 7 months, and carried out her duties as a salesgirl.

On November 14, 1944, or 237 days after the onset of the first attack of meningitis, the patient was admitted to the Haynes Memorial Hospital. During the previous 2 weeks she had developed a "head cold" with associated headache. During that time, the temperature ranged from 99 to 101°F and there were mild migratory joint pains involving the wrists, knees and elbows. Three days prior to entry, the patient noted some "red spots" on her legs, but had no further difficulty until the afternoon of the day of admission, when she had a sudden onset of a hard, shaking chill and a severe headache, with a rise in temperature to 104°F and delirium.

Physical examination on admission revealed a well developed, well nourished girl, appearing acutely ill and markedly delirious. The temperature was 100.4°F, the pulse 130, the respirations 24, and the blood pressure 130/70. There were a few pink macular areas scattered over the skin of the back and abdomen. The head was essentially normal. The pupils were round, regular and equal and reacted to light. There was a moderate degree of papilledema of both optic disks. The neck was markedly stiff. The lungs were clear on percussion and auscultation. Examination of the heart revealed no enlargement on percussion, the sounds were of good quality and the rhythm was regular. A Grade II systolic murmur was heard with greatest intensity over the mitral area but was not transmitted toward the axilla. The aortic second sound was greater than the pulmonic. The abdomen revealed no masses, spasm or detectable tenderness. The liver, spleen and kidneys were not palpable. The Kernig and Brudzinski signs were strongly positive bilaterally, and all the superficial and deep reflexes were markedly hyperactive but equal.

The urine on admission had a specific gravity of 1.020 and gave a +++ test for albumin; the sediment contained innumerable white cells and 40 to 100 red cells per high-power field. The white-cell count was 18,000, with 82 per cent neutrophils, of which 21 per cent were band forms, 12 per cent lymphocytes, 5 per cent monocytes and 1 per cent eosinophils. Lumbar puncture carried out immediately after admission revealed an initial pressure equivalent to 350 mm of water, with a normal rise and fall on jugular and abdominal compression. The spinal fluid contained 3230 cells per cubic millimeter, 95 per cent of which were polymorphonuclear leukocytes, and 21 mg of sugar, 97 mg of protein and 691 mg of chloride per 100 cc. A gram stain revealed many intracellular gram-negative biscuit-shaped diplococci, and a culture yielded organisms that were identified as *N meningitidis*, Type 1. Several blood cultures were sterile.

Because of the presence of moderately severe chronic renal disease and the risk of drug intoxication, the patient was treated with penicillin instead of one of the sulfonamides, being given 15,000 units intramuscularly every 3 hours for 10 days. In addition, 20,000 units was administered intrathecally on the 1st day and 40,000 units by the same route on the 2nd day. The temperature fell rapidly and reached a normal level on the 6th hospital day, at which time there was no evidence of delirium but signs of meningeal irritation were still present. Recovery was rapid, and on the 9th hospital day the cerebrospinal fluid contained only 57 lymphocytes per cubic millimeter and normal quantities of sugar, protein and chloride. A culture was negative.

Numerous examinations of the urine and studies of the chemical constituents of the blood established a diagnosis of chronic glomerulonephritis without azotemia or hypertension but with persistent hematuria, albuminuria and hypoproteinemia. The patient was kept in the hospital for 7 weeks after she had completely recovered from the meningitis for further investigation of the renal disease. There was no sign of reinfection of the meninges during this period. There was no evidence of an exacerbation of the glomerulonephritis during the course of the meningococcal infection.

On July 9, 1945, the patient was readmitted after having had a sore throat and fever for 2 days and four shaking chills with an elevation of temperature to 101°F on the day prior to entry. Physical examination revealed diminished resonance to percussion over the right upper lobe posteriorly, where there were heard many fine, moist rales. X-ray examination of the lungs revealed pneumonia of the right upper lobe.

The patient was treated with 120,000 units of penicillin a day for 8 days and made an uneventful recovery. Throat cultures revealed the presence of *N meningitidis*, Type 1.

the bladder (Fig 8) In pelvic trauma the bladder may be spared and the injury may be confined to the urethra (Fig 9)

From the foregoing, it is concluded that retrograde urethrocytography is an extremely accurate procedure if simple precautions are taken to avoid sources of error For these reasons, this should be a routine procedure in cases of suspected trauma of the lower urinary tract in which a definite diagnosis cannot be established by clinical examination

SUMMARY AND CONCLUSIONS

Seven cases of traumatic rupture of the bladder and posterior urethra are described

The diagnosis in these cases was established by retrograde urethrography and cystography with a radio-opaque contrast medium

A number of roentgenologic signs are described

that permit the differential diagnosis of intra peritoneal and extraperitoneal injuries

Certain fallacies of excretory and retrograde cystograms are pointed out

It is concluded that retrograde urethrocytography is a simple, safe and accurate method in the detection of trauma of the lower urinary tract

RECURRENT MENINGOCOCCAL MENINGITIS*

Report of a Case

LOUIS WEINSTEIN, M D,† AND EDITH D STANLEY, M D ‡

BOSTON

THE incidence of relapse in the course of meningococcal meningitis before the use of the sulfonamides in its treatment was about 50 per cent Since the universal adoption of this group of drugs as the therapeutic measure of choice, the relapse rate has dropped to only 8 per cent¹ True recurrence of this disease, on the other hand, is a rare phenomenon

For the purpose of discussion, it is important to differentiate a relapse from a true recurrence The former is defined in *Gould's Medical Dictionary*² as "a return of an attack of a disease shortly after the beginning of convalescence" The latter has been characterized by Schaffer and Freeman³ as "a fresh infection, a second attack, a repetition of the whole disease syndrome" Thus, a recurrence presupposes the passage of an appreciable period of time during which the patient is free of all symptoms of the original disease and, in many cases, has returned to normal activity By definition, it can occur only after the convalescent period has ended

Only a few well substantiated recurrences of meningococcal meningitis have been reported in the literature In 1919, Herrick and Dannenberg⁴ studied 4 patients who, after apparently having made a complete recovery from a first attack of this

disease, were victims of a second infection with the same organism after intervals of twenty-four, forty-three, one hundred and four and one hundred and forty-three days, respectively Bacteremia was present in each case during the second episode Rémond and Colombiès⁵ have described the case of a twenty-year-old medical student who had two attacks of meningococcal meningitis separated by a symptom-free period of eight months and completely recovered from each of them A case of recurrence seven months after the initial episode of infection of the meninges with *Neisseria meningitidis* has been reported by Christie⁶

A second attack of meningococcal meningitis may be due to invasion by the same serologic type as the one that was responsible for the first episode or a different one The source of the organisms causing the new infection may be a carrier or the patient himself, in the latter instance, the bacteria may be present in the pharynx or on damaged heart valves for long periods of time without producing any symptoms An example of a recurrence resulting from contact with a carrier of *N meningitidis* has been reported by Brewis,⁷ who described a patient who made good recoveries after two attacks of meningococcal meningitis separated by a period of four years, the second illness was treated with sulfonamides A possible case of a second attack in which the pharynx of the patient himself appeared to be the source of the infecting organisms was studied by Räuber⁸ This patient suffered two

Blood cultures were sterile. The patient was discharged completely recovered from the pneumonia 16 days after admission. The status of the renal disease was not altered by the pulmonary infection.

Bacteriologic examination of the pharynx on two occasions after the last discharge did not reveal the presence of meningococci.

DISCUSSION

This patient had chronic diffuse glomerulonephritis in the nephrotic stage and suffered two attacks of meningococcal meningitis during a period of seven months. The source of the bacteria that produced the two episodes of disease is unknown. Meningococcal meningitis was epidemic at the time of the first attack, in the spring of 1944, but only rare cases of this disease were occurring in this area at the time of the recurrence, in November, 1944. It is interesting, however, that the two episodes of meningitis occurred in the early spring and late fall, when the incidence of meningococcus carriers is apt to be high, and it is likely that a carrier was the source of infection. It does not appear probable that the recurrence was due to organisms present in the pharynx during the symptom-free period of seven months, since these organisms were not isolated from the throat during the second attack. The discovery of meningococci in the pharynx many months after recovery from the second episode of meningeal infection suggests a chronic carrier state. It is possible that these bacteria were present in extremely small numbers while the patient was well, increased during the bout of pneumonia and again disappeared.

The question of the relation of the nephrotic stage of the chronic diffuse glomerulonephritis to the increased susceptibility to bacterial infection is an interesting one, but no concrete evidence for a causal

connection between the two is at hand. Whether an analogy can be drawn between lipid nephrosis and the nephrotic state of chronic glomerulonephritis with respect to decreased resistance to infection is difficult to say. The repeated bacterial infections produced no exacerbation of the chronic renal disease.

SUMMARY

True recurrences of meningococcal meningitis are rare.

A case of chronic glomerulonephritis in which there were two attacks of meningococcal meningitis in seven months is described.

The question of the role of the nephrotic phase of chronic glomerulonephritis in increasing susceptibility to bacterial infection is raised.

Three episodes of severe bacterial infection exerted no noticeable effect on the course of chronic glomerulonephritis in the case reported.

complicated by the introduction of modified forms of insulin, such as protamine-zinc insulin, zinc insulin crystals and globin insulin. The introduction of a new technic for administering insulin mixtures has still further aggravated the problem.

It may be of interest to enumerate the variety of syringes that are sold to diabetic patients for the administration of insulin. They are as follows: a 1-cc syringe graduated in units, for use with U 10 and U 20 insulin, a 1-cc syringe graduated in units, for use with U 20 and U 40 insulin (Fig 1A), a 1-cc syringe graduated in units, for use with U 40 and U 80 insulin (Fig 1B), a 2-cc syringe graduated to 80 units, for use with U 40 protamine-zinc insulin (Fig 1C), a 2-cc syringe graduated to 80 and 160 units, for use with U 40 and U 80 protamine-zinc insulin, a 2-cc syringe graduated in tenths of a cubic centimeter and minims (Fig 1D), a 1-cc tuberculin-type syringe graduated in hundredths of a cubic centimeter (Fig 1E), and a 1-cc tuberculin-type syringe graduated in tenths of a cubic centimeter.

Insulin is generally administered either by the patient himself or by some member of his family, a neighbor, a practical nurse or a registered nurse. Only occasionally is it given by the physician. Although the latter can adapt himself to the use of a syringe of any type, it is difficult to avoid confusion in dosage when such a large variety of syringes is easily available to anyone else giving the injection, including the trained nurse. This statement is made as the result of practical experience and observation of the errors that have been made in the administration of insulin.

We know of patients using U 40 insulin who read their dose on the U 20 scale of a U 20-40 syringe. Thus, although the physician might have ordered the injection of 15 units of insulin, it is readily seen that the taking up of U 40 insulin to the "15" mark on the U 20 scale would actually result in a dose of 30 units. This happens to be the most frequent type of error. It appears that the reason for it is that the graduations on the U 20 scale are wider and the figures are larger than those on the U 40 scale, thus making them more easily seen, especially by a patient whose vision is not particularly good.

One of the most dangerous errors in the administration of insulin occurs when a patient uses an ordinary hypodermic syringe graduated in cubic centimeters and minims (Fig 1D). We recall a patient who appeared for the first time with the chief complaint of frequent insulin reactions. She had been diabetic for five years and had taken insulin for three years. She had apparently encountered difficulty in controlling her glycosuria and had changed from U 40 insulin to U 80 insulin, because, she said, U 80 insulin was "stronger." She had also been advised by her physician to change from unmodified insulin to protamine-zinc

insulin. Inquiry into the type of syringe employed revealed that she was using an ordinary 2-cc hypodermic syringe. Although she stated that she was taking "24 units" of protamine-zinc insulin, she was in fact receiving 24 minims. The latter amount is approximately equivalent to 1.5 cc, and in terms of U 80 insulin it is evident that this patient was taking 120 units of insulin. Her hypoglycemic

FIGURE 2

reactions therefore caused little surprise when it was ultimately found that the daily insulin requirement for the satisfactory control of her diabetes was only 45 units.

A registered nurse who was diabetic was taking U 80 protamine insulin up to the "35" mark on the 40-unit scale of a U 20-40 syringe. She assumed that she was injecting 35 units when in reality she was injecting 70 units.

It is evident that such practices can result only in accidents from the toxic effects of insulin overdosage. These errors are made largely because of the fact that the instruction in insulin administra-

tion is too haphazard. The physician frequently fails to recognize that successful therapy is predicated on adequate and painstaking instruction. Teaching the technic of proper insulin administration should not be left to an inexperienced attendant or a neighbor or relative of the patient who happens to be taking insulin. The patient can with only a little effort be taught the exact technic for the proper administration of the kind and dose of insulin he should receive.

Simplification in the administration of insulin can be achieved, first, by the elimination of U 10 and U 20 strength insulin from the market, which has been recommended by the American Diabetes Association. If this were done, only two concentrations of insulin, U 40 and U 80, would be available. The most effective remedy, however, would be the elimination of the insulin syringe with dual markings. Only two types of syringes should be available to the patient—one with a single scale graduated to 40 units and to be used with U 40 insulin only (Fig 2C), and the other graduated for U 80 insulin only (Fig 2A and B). The syringe with calibrations for U 40 insulin should be manufactured in the 1-cc. size only. Those employed for the administration of U 80 insulin should be made in 1-cc. and 2-cc. sizes, with the former calibrated to 80 units and the latter to 160 units. The 2-cc. syringe is recommended for patients who take insulin in doses greater than 80 units. It is also useful for patients to whom insulin mixtures are given, with the total

dose of unmodified and protamine-zinc insulin exceeding 80 units.

To emphasize further the separate identity of these syringes, the graduations and lettering of the U 40 syringe should be etched in red to conform with the red label and cap of the U 40 insulin vial, and the U 80 syringes should be etched in green to conform with the label and cap of the U 80 insulin vial. To ensure further against the possibility of error, the printed matter on both the syringe and the cardboard container in which it is sold should read, "This syringe is to be used for U 40 insulin only" and "This syringe is to be used for U 80 insulin only," respectively.

It is suggested that when physicians find that they must prescribe more than 40 units of insulin in a single dose, they recommend the use of U 80 insulin only, and that when this change is made the patient be instructed to use only a U 80 insulin syringe. In the meantime, until the manufacturers can be persuaded to produce syringes according to the recommendations made herein, physicians should prescribe only the U 40-80 syringe and impress the patient with the importance of employing the appropriate scale for the insulin ordered.

SUMMARY

The confusion caused by insulin syringes with dual calibrations is pointed out.

Recommendations are made for the manufacture of syringes with simplified graduations to eliminate the possibility of error in dosage.

CLINICAL NOTE

ARTERIOVENOUS ANEURYSM OF THE GREAT VESSELS OF THE NECK

REPORT OF A CASE

COLONEL PHILLIPS L. BOYD, MC, AUS*

ARTERIOVENOUS aneurysms and fistulas are lesions of comparative rarity, even in wartime. The incidence of these vascular injuries in this general hospital in the European Theater of Operations has been 1 in every 500 admissions. All the cases except the one reported herein occurred in the vessels of an extremity.

The problems of diagnosis and of the determination of adequate collateral circulation prior to surgical intervention have been well covered by Lewis and Drury,¹ Wise,² Waugh,³ Pemberton and Black⁴ and King.⁵ The following case of arteriovenous aneurysm involving the internal carotid artery and internal jugular vessels is reported because of the technical complications inherent in its location and because of the excellent surgical result obtained.

CASE REPORT

A 35-year-old, German soldier was wounded in action near Paris on August 23, 1944, and sustained penetrating wounds of the left wrist from fragments of high-explosive shell, with a compound comminuted fracture of the distal end of the radius and ulna and wounds of the right upper arm and shoulder and right side of the neck at the level of the thyroid cartilage.

At the forward medical installations, the wounds were debrided and dressed and the fractured wrist was immobilized in a cast. Sulfonamides, penicillin and 1500 units of tetanus antitoxin were administered. Four days later, at a transit hospital, it was noted that a pulsating mass had appeared on the right side of the neck at the level of the thyroid cartilage. It was thought that an arteriovenous fistula was present and that an arteriovenous aneurysm might be developing.

On admission to this hospital on September 6, 1944, the patient was ambulatory. The voice was husky and hoarse. The left wrist and forearm were in a cast, and the wounds were healing well. Physical examination revealed a mass 2.5 by 3.0 cm. in diameter on the right side of the neck just lateral and superior to the thyroid cartilage, with slight visible pulsation, a marked tactile thrill and a loud auscultatory bruit, which was transmitted along the great vessels into the base of the neck and out along the supraclavicular vessels on the right. Neurologic examination showed a Horner's syndrome on the right and paralysis of the right vocal chord. The wrist was poorly reduced, and there was considerable loss of motion.

X-ray examination on September 14 revealed a fragment of metal measuring 0.5 by 0.5 by 0.2 cm. just lateral to the right side of the superior border of the fifth cervical vertebra. A film of the left wrist showed the fracture to be poorly reduced. Further studies with compression of the mass by digital pressure indicated that the circle of Willis and the cerebral collateral vessels could probably maintain adequate circulation to the cerebrum. Studies of the blood pressure in the right and left arms were not done. Inasmuch as the mass was constantly enlarging and it was impossible to maintain adequate local compression, it was decided to excise the lesion. Cardiac studies showed no change in its size.

*Instructor in surgery, Boston University School of Medicine and assistant in surgery, Massachusetts Memorial Hospitals (on leave of absence).

On September 19, 4 weeks after injury, operation was performed under gas, oxygen and ether anesthesia. A downward incision was made from the mastoid process to the clavicle along the anterior margin of the right sternomastoid muscle. The carotid sheath was opened at the level of the isthmus of the thyroid gland, the common carotid artery and internal jugular vessels were isolated, and the artery was slowly compressed with a clamp, 45 minutes being required before closure was complete. Exploration of the mass revealed that it was an aneurysmal sac occupying the middle three fifths of the sternomastoid muscle (Fig. 1). The mass

FIGURE 1 Aneurysmal Mass Uncovered in Right Side of Neck

was contained only by the attenuated fibers of this muscle and its fascial sheath and by the platysma muscle. In an effort to open the carotid sheath above the mass, the sac was ruptured, and from then on bleeding was controlled by digital pressure. The common carotid artery and internal jugular vein were ligated proximal to the lesion. After considerable difficulty, the internal jugular vein was ligated distally nearly at the level of its emergence from the skull. A double ligature was then passed around the internal jugular and internal carotid vessels distal to the lesion. All bleeding ceased, and the aneurysmal wall, which consisted of friable muscle tissue lined with a glossy endothelial layer, was dissected out. The arteriovenous fistula (Fig. 2) had developed between the internal carotid artery and the internal jugular vein at a point 1 cm. beyond the bifurcation of the common carotid artery.

The small metallic foreign body (Fig. 2) had completely traversed the carotid sheath at the level of the thyroid cartilage, injuring the wall of the internal carotid artery and internal jugular vein, completely transecting the vagus nerve—causing a spindle-shaped neuroma 0.3 cm. in diameter—and injuring the cervical sympathetic trunk. The foreign body could not be palpated and was not removed. The wound was closed in three layers with a rubber-dam drain, which was brought out at the inferior angle of the wound.

During the operation the patient was supported by the intravenous injection of 500 cc. of plasma, 1500 cc. of stored whole blood and 500 cc. of glucose in saline solution. The entire operation lasted for 3 hours. The patient was returned to the ward in good condition.

The patient was stuporous for 48 hours postoperatively but rallied quickly. On the 14th postoperative day, he was up and about. The wound was discharging a slight amount of seropurulent material. No evidence of cerebral damage could be detected. The Horner's syndrome and the paralysis of the right vocal chord persisted, although the voice was stronger and less husky, probably owing to the release of

pressure on the larynx. The wrist had to be reset, but even after this step there was considerable loss of motion. The patient was able to perform routine work details and was evacuated to a prisoner-of-war camp 6 weeks postoperatively, in excellent condition.

As a general policy, early operation in cases of arteriovenous fistula or aneurysm is not necessary. In fact, many surgeons believe that it may be unwise, since adequate collateral circulation has not had time to develop. Lewis and Drury,¹ in their excellent study, state their opinion that the alterations that occur in the part of the vascular tree

aneurysms in 3 German prisoners of war were successfully operated on within one month of the injury. In cases in which distal pulsations are present, further study with digital pressure over the involved point must be accomplished, and observation of the color and temperature changes of the limb must be made.

King⁵ has reported a case closely similar in location to the one described above. It was also treated by ligation above and below the lesion, eight weeks after injury, during which time the patient developed cardiac enlargement and blood-pressure changes. In the present case, operation was performed four weeks after injury, and so far as could be detected no cardiac changes occurred.

It is the policy in this theater to refer most cases of arteriovenous aneurysm or fistula to the Zone of the Interior for operation. In rapidly developing lesions of the great vessels of the neck or thorax, however, surgical control is often inadequate and cardiac changes may develop early. With a proper understanding of the technical complications, early operation can be successfully performed, and it offers the only chance of cure and avoidance of cardiac damage.

SUMMARY

An unusual case of arteriovenous aneurysm of the great vessels of the neck is reported. Although operation was considered necessary four weeks after injury, the patient made a rapid and complete recovery.

peripheral to a fistula are such that if from the start there is no evidence of gross circulatory failure, surgical interference with a large vessel, a procedure that in ordinary circumstances might lead to serious complications, can be undertaken with impunity. Most of the peripheral aneurysms seen in war wounds on this service have shown a loss of distal pulsation but have had evident adequate distal circulation. A case requiring amputation for circulatory gangrene showed an arteriovenous aneurysm of the popliteal vein and artery. Operation, therefore, in the average case in no way seriously alters the vascular balance of the limb. Such

CLINICAL NOTE

ARTERIOVENOUS ANEURYSM OF THE GREAT VESSELS OF THE NECK

REPORT OF A CASE

COLONEL PHILLIPS L. BOYD, MC, A.US.*

ARTERIOVENOUS aneurysms and fistulas are lesions of comparative rarity, even in wartime. The incidence of these vascular injuries in this general hospital in the European Theater of Operations has been 1 in every 500 admissions. All the cases except the one reported herein occurred in the vessels of an extremity.

The problems of diagnosis and of the determination of adequate collateral circulation prior to surgical intervention have been well covered by Lewis and Drury,¹ Wise,² Waugh,³ Pemberton and Black⁴ and King.⁵ The following case of arteriovenous aneurysm involving the internal carotid artery and internal jugular vessels is reported because of the technical complications inherent in its location and because of the excellent surgical result obtained.

CASE REPORT

A 35-year-old, German soldier was wounded in action near Paris on August 23, 1944, and sustained penetrating wounds of the left wrist from fragments of high-explosive shell, with a compound comminuted fracture of the distal end of the radius and ulna and wounds of the right upper arm and shoulder and right side of the neck at the level of the thyroid cartilage.

At the forward medical installations, the wounds were debrided and dressed and the fractured wrist was immobilized in a cast. Sulfonamides, penicillin and 1500 units of tetanus antitoxin were administered. Four days later, at a transit hospital, it was noted that a pulsating mass had appeared on the right side of the neck at the level of the thyroid cartilage. It was thought that an arteriovenous fistula was present and that an arteriovenous aneurysm might be developing.

On admission to this hospital on September 6, 1944, the patient was ambulatory. The voice was husky and hoarse. The left wrist and forearm were in a cast, and the wounds were healing well. Physical examination revealed a mass 2.5 by 3.0 cm in diameter on the right side of the neck just lateral and superior to the thyroid cartilage, with slight visible pulsation, a marked tactile thrill and a loud auscultatory bruit, which was transmitted along the great vessels into the base of the neck and out along the supraclavicular vessels on the right. Neurologic examination showed a Horner's syndrome on the right and paralysis of the right vocal chord. The wrist was poorly reduced, and there was considerable loss of motion.

X-ray examination on September 14 revealed a fragment of metal measuring 0.5 by 0.5 by 0.2 cm just lateral to the right side of the superior border of the fifth cervical vertebra. A film of the left wrist showed the fracture to be poorly reduced. Further studies with compression of the mass by digital pressure indicated that the circle of Willis and the cerebral collateral vessels could probably maintain adequate circulation to the cerebrum. Studies of the blood pressure in the right and left arms were not done. Inasmuch as the mass was constantly enlarging and it was impossible to maintain adequate local compression, it was decided to excise the lesion. Cardiac studies showed no change in its size.

*Instructor in surgery, Boston University School of Medicine and assistant in surgery, Massachusetts Memorial Hospitals (on leave of absence).

On September 19, 4 weeks after injury, operation was performed under gas, oxygen and ether anesthesia. A downward incision was made from the mastoid process to the clavicle along the anterior margin of the right sternomastoid muscle. The carotid sheath was opened at the level of the isthmus of the thyroid gland, the common carotid artery and internal jugular vessels were isolated, and the artery was slowly compressed with a clamp, 45 minutes being required before closure was complete. Exploration of the mass revealed that it was an aneurysmal sac occupying the middle three fifths of the sternomastoid muscle (Fig 1). The mass

FIGURE 1 Aneurysmal Mass Uncovered in Right Side of Neck

was contained only by the attenuated fibers of this muscle and its fascial sheath and by the platysma muscle. In an effort to open the carotid sheath above the mass, the sac was ruptured, and from then on bleeding was controlled by digital pressure. The common carotid artery and internal jugular vein were ligated proximal to the lesion. After considerable difficulty, the internal jugular vein was ligated distally nearly at the level of its emergence from the skull. A double ligature was then passed around the internal jugular and internal carotid vessels distal to the lesion. All bleeding ceased, and the aneurysmal wall, which consisted of friable muscle tissue lined with a glossy endothelial layer, was dissected out. The arteriovenous fistula (Fig 2) had developed between the internal carotid artery and the internal jugular vein at a point 1 cm beyond the bifurcation of the common carotid artery.

The small metallic foreign body (Fig 2) had completely traversed the carotid sheath at the level of the thyroid cartilage, injuring the wall of the internal carotid artery and internal jugular vein, completely transecting the vagus nerve—causing a spindle-shaped neuroma 0.3 cm in diameter—and injuring the cervical sympathetic trunk. The foreign body could not be palpated and was not removed. The wound was closed in three layers with a rubber-dam drain, which was brought out at the inferior angle of the wound.

During the operation the patient was supported by the intravenous injection of 500 cc of plasma, 1500 cc of stored whole blood and 500 cc of glucose in saline solution. The entire operation lasted for 3 hours. The patient was returned to the ward in good condition.

The patient was stuporous for 48 hours postoperatively but rallied quickly. On the 14th postoperative day, he was up and about. The wound was discharging a slight amount of seropurulent material. No evidence of cerebral damage could be detected. The Horner's syndrome and the paralysis of the right vocal chord persisted, although the voice was stronger and less husky, probably owing to the release of

ture Increased fever and prolonged febrile response to typhoid vaccine can be obtained by the concomitant use of a covered cradle containing electric-light bulbs⁴⁶ The reported results are encouraging, especially when combined with chemotherapy

A report on the use of thiamine by spinal injection for the relief of the pains of tabetic crises⁴⁷ seems encouraging enough to warrant further study

Intensive Therapy

The various types of massive-dose technic that have been under study for the last twelve years are still undergoing refinement The United States Army hospital installations in the European Theater of Operations carried out treatment by the twenty-day multiple-syringe injection technic⁴⁸ Patients were hospitalized during this time, many received a course of ten bismuth injections after discharge from the hospital Reactions encountered were comparable to those previously experienced with this type of treatment Although follow-up of the patients was incomplete, the results appeared extremely satisfactory for periods of four to six months Only 1 of 205 patients with seronegative primary syphilis showed a doubtful serologic reaction four months or more after treatment The subsequent use of penicillin therapy interrupted this program

MacKee and Astrachan⁴⁹ treated 61 patients by the method of Eagle and Hogan,^{50, 51} which consists of tri-weekly injections of Mapharsen for twelve weeks, combined with one bismuth injection each week These authors find this to be an efficacious method, with fewer reactions than the intravenous drip treatment, but caution that it is still in the experimental stage Less encouraging results have been observed by others⁵² with a slightly less intensive schedule A daily injection of Mapharsen for thirty days, without bismuth, resulted in only 51 per cent seronegative reactions among 62 patients with early syphilis A four-year experience with the five-day-drip method has also been reported⁵³ One hundred patients were treated, but only 50 were followed up for periods of one to three or more years Only 4 cases are classified as treatment failures There was 1 fatality, which was due to hemorrhagic encephalitis

Further observations on the one-day treatment of syphilis with fever and Mapharsen have appeared⁵⁴, 421 patients with early syphilis are included They were treated by several schedules, including the administration of Mapharsen during the induction period, before and after the fever and at its termination The best results were obtained among the 206 patients so treated after the termination of fever These were observed for three to nine months, only 16 (8 per cent) showed a clinical relapse, and only 5 (2 per cent) a serologic relapse Only forty-eight hours of hospitalization was required The cost per case was estimated at \$30

A word of caution concerning the rapid treatment

of early syphilis during pregnancy should be carefully noted One of a series of 43 pregnant patients with early syphilis died of encephalopathy⁵⁵

The United States Public Health Service⁵⁶ has published its evaluation of massive arsenotherapy The data were taken from 4351 cases treated at twenty-two clinics by six varied plans The best results exclusive of the highly reactive intravenous-drip technic with neoarsphenamine, followed the use of multiple-syringe injections of Mapharsen combined with typhoid vaccine This yielded satisfactory results in 85 to 90 per cent of the cases of primary syphilis and in 70 per cent of those of secondary syphilis Relapse occurred in 5 to 6 per cent of the primary cases and 10 to 13 per cent of the secondary cases The administration of bismuth during the period of treatment appeared to improve the results Acute encephalopathy was observed in 31 cases (0.71 per cent), and nearly half of these patients died

REACTIONS TO TREATMENT

Bismuth

Heyman⁵⁷ has presented a review of the literature on bismuth poisoning and reports observations on 4 patients with severe systemic manifestations and renal insufficiency following bismuth therapy Bismuth melanosis of the large intestine and bismuth cervicovaginitis occurred in 2 cases The author believes that these conditions occur oftener than has been reported The renal lesions in these patients were closely similar to those produced in animals by experimentation In all 4 patients, the nephrotoxic action of the drug produced an intensification of pre-existing renal insufficiency In 2 of them, the effect was temporary and a fair degree of renal function returned in a few months, death resulted in the others It is obvious that great caution is necessary with the use of bismuth in patients who already have some renal damage

Dental examination of approximately 500 soldiers receiving bismuth treatment for syphilis revealed that 70 per cent of them had some gingival manifestation of bismuth deposit⁵⁸ The condition appeared chiefly in the patients who had failed to practice oral hygiene The bluish-black line is first seen at the site of any pre-existing inflammation The standard dose of 0.13 to 0.20 gm of bismuth salicylate, it is stated, should cause little or no disturbance if oral hygiene is good, provided that injections are not extended beyond a series of twelve to fifteen treatments Only in cases of gross negligence or intolerance to bismuth does a severe stomatitis develop

Post-Arsphenamine Jaundice

Beattie and Marshall⁵⁹ discuss the etiology of post-arsphenamine jaundice It is stated that although the organic arsenicals used in the treatment of syphilis are hepatotoxic, there are indica-

BOSTON

THERAPY

The use of penicillin in the treatment of syphilis has developed with an explosive force almost analogous to that of the atomic bomb. The literature on this particular phase of the treatment of syphilis is so voluminous as to warrant a completely separate category. Consequently, it will be discussed in a separate section of this progress report.

Moore⁴² has given a most instructive discussion of the chemotherapy of syphilis from the time of the first knowledge of the disease. This covers a period of four hundred and fifty-one years, which is divided into three main periods according to the advances made in chemotherapeutics. The first dates from 1493 to 1903, during which time little was accomplished. From 1903 until 1943, great gains were made, including the discovery of the causative agent of syphilis, the serologic test for syphilis and the use of bismuth, massive-dose technic, hyperpyrexia and combined-treatment programs. The last period of course begins with the advent of penicillin. The accomplishments of this drug up to the time of writing are adequately reviewed, and the limitations of the present knowledge are carefully pointed out. Moore stresses the fact that with all types of syphilotherapy it has taken some time to work out the optimal time-dose relation. This is obviously as true of penicillin as it is of older forms of treatment. Moore believes that penicillin, in combination with an arsenoxide, may prove to be more effective than either drug alone, and outlines the dose schedules that are under trial at the present time. He stresses the fact that the late results of any of the intensive methods of therapy will not be available for another generation. This point has been repeatedly emphasized in these columns during the last few years.

Oral Bismuth

Barnett and Meininger⁴³ have published a follow-up report on the use of oral bismuth medication in the form of so-called "sobisminol mass." There are several categories of patients in which oral treatment for syphilis is particularly useful. These include those unable to consult a physician at regular intervals owing to occupation, isolated residence, inadequate transportation and so forth. Tertiary syphilis associated with chronic invalidism

is another indication for oral treatment. There are also some patients who refuse parenteral therapy for various reasons. Sobisminol mass alone is not recommended for the treatment of early syphilis, but it may be substituted for bismuth by injection in conjunction with arsenotherapy if necessary. In late syphilis, sobisminol mass produced a rapid involution of gummatous lesions, and a number of patients with advanced cardiovascular involvement and neurosyphilis were symptomatically improved by its administration. The toxicity of sobisminol mass is low. One third of 400 patients experienced mild gastrointestinal disturbances, but in less than one fifth of these was it necessary to discontinue the drug. Although one may now hope for therapeutically efficient oral penicillin, this work with oral bismuth should not be entirely forgotten.

Neurosyphilis

Solomon, Moore, O'Leary, Stokes and Thomas⁴⁴ outline the treatment methods recommended for the various forms of neurosyphilis to obtain the maximum benefit of treatment that can be secured by hospitalization in a general hospital, not to exceed three months. They divide neurosyphilis into nine groups for the purpose of therapy, and outline the most desirable form of treatment for each. Chemotherapy is advocated following fever therapy in most cases, as soon as malaria is terminated and during convalescence from this infection. Injections of Mapharsen (0.06 gm.) are to be given daily for ten days. The need of subsequent chemotherapy is determined by observation of the case in hand. Here again, the results of penicillin therapy may warrant changes.

The simpler method of inducing hyperpyrexia by intravenous drip with triple-typhoid vaccine should not be overlooked. Although not all patients achieve a satisfactory febrile response to this treatment, it is often usable in cases in which malaria is not well tolerated. In a series of 60 cases of various types of neurosyphilis treated by this method, there was a satisfactory response in early paresis and in asymptomatic neurosyphilis.⁴⁵ The advantages of this method of hyperpyrexia over malaria in a general hospital include shorter hospitalization, greater convenience, greater ease of administration and better control of the tempera-

syphilis is a disease in which penicillin has been found to be an effective agent, but that its position has not been definitely defined and will require additional experimental work

Effect on Treponema pallidum

It has been demonstrated that *Treponema pallidum* can become resistant to penicillin⁷⁰ The work was done with experimental infection of rabbits, which were given sufficient penicillin to modify the course of the disease but not enough to effect a cure. This resulted in the development of a penicillin-fast strain, which persisted after further animal passages. This emphasizes the necessity for adequate treatment with penicillin in clinical cases. It has further been shown that although a single dose of penicillin may sterilize an infectious lesion, even an extremely high single dose is not sufficient to cure experimental syphilis in rabbits⁷¹ This is a good example of the importance of the time-dose relation.

Dunham and Rake⁷² report the results of experiments performed in vitro and in vivo to determine the relative activity of partially purified penicillin and of crystalline penicillin G on *T. pallidum*. Crystalline penicillin G in a high concentration had little or no effect on the motility of the organism in vitro. Under the same conditions, a solution containing one fourth as much of the least pure penicillin preparation employed in these studies immobilized all the spirochetes. *T. pallidum* exposed to certain partially purified preparations of penicillin was noninfectious for rabbits, whereas spirochetes similarly exposed to crystalline penicillin G produced orchitis. It was demonstrated, however, that crystalline penicillin G had some antisyphilitic action. It failed to protect rabbits against infection of syphilis unless given in tremendous doses, whereas partially purified penicillin protected a large proportion of rabbits when small doses were given.

Prolongation of Action

A great deal of work has been directed toward establishing methods of administration to provide the maintenance of adequate blood levels of penicillin with less frequent treatments. Several successful methods have been reported⁷³⁻⁷⁹ The first was by excretory blockade, effected by the simultaneous intramuscular injection of Diodrast or para-aminohippuric acid. The second method accomplished the same result by suspending penicillin in inert oils that slowed down the rate of absorption from locally injected tissues. A mixture of peanut oil and 1 to 6 per cent of beeswax gave the best results. The third successful method is based on an attempt to delay absorption by pronounced vasoconstriction in the injected muscle through chilling with an ice pack. Adrenalin and longer-acting vasoconstrictor drugs, such as Privine

and Neo-Synephrine, together with gelatin have been shown to prolong the action of penicillin. A combination of dextrose with a vasoconstrictor has also been found to furnish a satisfactory and harmless extension of action⁸⁰ Zinnamon⁸¹ studied the retardation of intramuscular absorption of penicillin combined with aluminum hydroxide, pectin, globin and various fixed oils. The fixed oils effected the most retardation, a mixture of beeswax and sesame oil being the most satisfactory. The use of pitressin subcutaneously to produce oliguresis during periods of penicillin therapy has been suggested⁸² Colloidal penicillin, formed by the combination of crystalline penicillin with human plasma protein to make a large penicillin-protein complex, is apparently more slowly absorbed from the injected muscle and more slowly excreted by the kidneys than is free or unbound penicillin⁸³ This work was done with mice, and the therapeutic efficiency in man is now under investigation. The oral administration of benzoic acid, combined with restriction of caloric intake, fluids and salt, has been found to increase the penicillin blood level, with a prolonged effective blood concentration following intramuscular injection of the drug⁸⁴

Of these numerous methods of prolonging the action of penicillin, several hold much promise. It is to be hoped that a practical and effective plan will be worked out in the near future so that more efficient use can be made of this remarkable agent.

Oral Administration

A considerable number of papers concerning the use of penicillin by mouth have appeared. Simplified methods of administering the drug that will provide adequate and prolonged blood concentrations are being sought by many investigators,⁸⁵⁻⁹⁰ and it is natural that oral administration should be attempted. The destructive action on penicillin by the hydrochloric acid in the stomach can be eliminated by the use of the buffer action of trisodium citrate, disodium phosphate or sodium bicarbonate. The stabilizing effect of protein is also useful, such as penicillin mixed with raw egg. Enteric-coated penicillin tablets gave unsatisfactory results, but penicillin in an oil or fat suspension has proved therapeutically effective. Cottonseed oil, corn oil, peanut oil and beeswax have been used. A method of oral administration of penicillin modified with aluminum hydroxide or magnesium hydroxide has been found effective⁹¹ Because of prolonged penicillin concentrations in the blood following this method of oral administration, it may have some prophylactic value.

The advantages of giving penicillin by mouth include ease of administration and avoidance of hospitalization, with its attendant economic burden. Relatively crude or impure penicillin would presumably be satisfactory. Therapeutically effective blood levels can be maintained by several of the

tions that they are not solely responsible for post-arsphenamine jaundice. During both world wars a definite relation between the increased incidence of jaundice in the general population and the increased number of cases of post-arsphenamine jaundice was observed. Although an analysis of 119 cases suggested that there was some relation between infective jaundice and post-arsphenamine jaundice, this could not be proved. An attack of late post-arsphenamine jaundice presumably confers no immunity against infective jaundice. Evidence that an attack of infective jaundice also confers no immunity against post-arsphenamine jaundice is incomplete but suggestive.

A case of jaundice following the injection of Mapharsen exhibited clinical and laboratory data consistent with the diagnosis of extrahepatic biliary obstruction.⁶⁰ This was not confirmed at operation, and biopsy of the liver showed that the jaundice was intrahepatic. During the course of the disease, the patient developed a syndrome that resembled sprue in many respects. This is unusual.

There has been considerable difference of opinion in the past regarding continuance of antisyphilitic therapy after the development of jaundice. It is generally agreed that arsenotherapy must be stopped for a period of at least several months, but some investigators have concluded that it is safe to continue bismuth. Forbes⁶¹ compared two groups of patients with post-arsphenamine jaundice, one of which was continued on intramuscular injections of bismuth and the other of which received no further antisyphilitic treatment. Clinically, there was no significant difference in the progress of the two groups. The results of liver-function tests indicated that bismuth therapy did not significantly retard recovery of liver function in the treated cases. Such a result supports the view that bismuth therapy may be continued in the presence of jaundice of this nature.

Blood Dyscrasias

In general, Mapharsen has produced fewer reactions than has any of its predecessors. A number of reports have appeared during the past year, however, regarding damage to blood-forming organs from the use of this drug. Agranulocytosis is recorded in 5 cases and from three different sources.⁶²⁻⁶⁴ Aplastic anemia, acute agranulocytosis and thrombopenic purpura are all described as complicating Mapharsen therapy in the same patient.⁶⁵ Thrombocytopenic purpura is listed separately.⁶⁶

Hemorrhagic Encephalitis

In addition to the cases already referred to,^{53, 55, 56} a discussion of 5 patients with hemorrhagic encephalitis has been published by Lydon.⁶⁷ These cases comprise 9 per cent of 53 treated for early syphilis by an intensive course of multiple injections of Mapharsen. The author gives a detailed descrip-

tion of their courses. He believes that alcoholism may be a predisposing factor, as may also a deficiency of vitamin B₁. Microscopic changes in the liver found at autopsy supported the latter concept. It is suggested that primary cellular damage of the brain tissue itself is a likelier pathologic development than that predicated by the more usually accepted vascular toxic theory. In addition to the customary treatment of venesection, repeated lumbar punctures and adrenalin, the author suggests vitamin B₁ as both a prophylactic and a therapeutic agent. He also used calcium gluconate as an adjunct.

PENICILLIN

From the information so far available, penicillin seems to be a therapeutic agent of immeasurable value for the treatment of syphilis, with the reservation that the optimal dosage and time-dose relation is not yet fully understood. Emphasis should again be laid on the time required to assay the value of any treatment in syphilis. It will probably be not less than twenty years before the final results of penicillin therapy can be evaluated. Some observers believe that this drug should not be used in the treatment of syphilis outside of research institutions. Nelson⁶⁸ states that it should not be employed in private practice or as routine therapy anywhere unless adequate follow-up facilities are available. He goes on to point out that it is not yet certain that the penicillin itself is the effective agent, since the alleged impurities present in commercial preparations may possibly be of greater value than the penicillin. Moore⁶⁹ thinks that there is still much to be learned regarding dosage.

It is generally agreed that a total dosage less than 1,200,000 units is followed by an extremely high relapse rate, even with this amount, a relapse rate of 15 to 20 per cent is experienced in early syphilis. It is known that intramuscular injections at three-hour intervals day and night are required. Increasing the amount of penicillin given at three-hourly intervals to reduce the duration of treatment is not helpful. It is known that penicillin is apparently effective in cases of early syphilis that are resistant to arsenic and bismuth. There is some evidence that penicillin in combination with an arsenoxide is more effective than either drug alone. A number of dose schedules are under trial in various treatment centers. Reactions from penicillin have so far been negligible except for the Jarisch-Herxheimer reaction. The present minimum requirement of ten days' hospitalization imposes such an economic burden as to preclude the use of penicillin in many cases. Much work is being done to establish a method for use in ambulatory patients.

Further evidence of the lack of knowledge of this subject can be found in the latest publication of indications and dosage schedules for certifiable penicillin products.⁶⁹ It is stated therein that

syphilis is a disease in which penicillin has been found to be an effective agent, but that its position has not been definitely defined and will require additional experimental work

Effect on Treponema pallidum

It has been demonstrated that *Treponema pallidum* can become resistant to penicillin⁷⁰ The work was done with experimental infection of rabbits, which were given sufficient penicillin to modify the course of the disease but not enough to effect a cure This resulted in the development of a penicillin-fast strain, which persisted after further animal passages This emphasizes the necessity for adequate treatment with penicillin in clinical cases It has further been shown that although a single dose of penicillin may sterilize an infectious lesion, even an extremely high single dose is not sufficient to cure experimental syphilis in rabbits⁷¹ This is a good example of the importance of the time-dose relation

Dunham and Rake⁷² report the results of experiments performed in vitro and in vivo to determine the relative activity of partially purified penicillin and of crystalline penicillin G on *T. pallidum* Crystalline penicillin G in a high concentration had little or no effect on the motility of the organism in vitro Under the same conditions, a solution containing one fourth as much of the least pure penicillin preparation employed in these studies immobilized all the spirochetes *T. pallidum* exposed to certain partially purified preparations of penicillin was noninfectious for rabbits, whereas spirochetes similarly exposed to crystalline penicillin G produced orchitis It was demonstrated, however, that crystalline penicillin G had some anti-syphilitic action It failed to protect rabbits against infection of syphilis unless given in tremendous doses, whereas partially purified penicillin protected a large proportion of rabbits when small doses were given

Prolongation of Action

A great deal of work has been directed toward establishing methods of administration to provide the maintenance of adequate blood levels of penicillin with less frequent treatments Several successful methods have been reported⁷³⁻⁷⁹ The first was by excretory blockade, effected by the simultaneous intramuscular injection of Diodrast or para-aminohippuric acid The second method accomplished the same result by suspending penicillin in inert oils that slowed down the rate of absorption from locally injected tissues A mixture of peanut oil and 1 to 6 per cent of beeswax gave the best results The third successful method is based on an attempt to delay absorption by pronounced vasoconstriction in the injected muscle through chilling with an ice pack Adrenalin and longer-acting vasoconstrictor drugs, such as Privine

and Neo-Synephrine, together with gelatin have been shown to prolong the action of penicillin A combination of dextrose with a vasoconstrictor has also been found to furnish a satisfactory and harmless extension of action⁸⁰ Zinnamon⁸¹ studied the retardation of intramuscular absorption of penicillin combined with aluminum hydroxide, pectin globin and various fixed oils The fixed oils effected the most retardation, a mixture of beeswax and sesame oil being the most satisfactory The use of pitressin subcutaneously to produce oliguresis during periods of penicillin therapy has been suggested⁸² Colloidal penicillin, formed by the combination of crystalline penicillin with human plasma protein to make a large penicillin-protein complex, is apparently more slowly absorbed from the injected muscle and more slowly excreted by the kidneys than is free or unbound penicillin⁸³ This work was done with mice, and the therapeutic efficiency in man is now under investigation The oral administration of benzoic acid, combined with restriction of caloric intake, fluids and salt, has been found to increase the penicillin blood level, with a prolonged effective blood concentration following intramuscular injection of the drug⁸⁴

Of these numerous methods of prolonging the action of penicillin several hold much promise. It is to be hoped that a practical and effective plan will be worked out in the near future so that more efficient use can be made of this remarkable agent.

Oral Administration

A considerable number of papers concerning the use of penicillin by mouth have appeared Simplified methods of administering the drug that will provide adequate and prolonged blood concentrations are being sought by many investigators,⁸⁵⁻⁹⁰ and it is natural that oral administration should be attempted The destructive action on penicillin by the hydrochloric acid in the stomach can be eliminated by the use of the buffer action of trisodium citrate, disodium phosphate or sodium bicarbonate The stabilizing effect of protein is also useful, such as penicillin mixed with raw egg Enteric-coated penicillin tablets gave unsatisfactory results, but penicillin in an oil or fat suspension has proved therapeutically effective Cottonseed oil, corn oil, peanut oil and beeswax have been used A method of oral administration of penicillin modified with aluminum hydroxide or magnesium hydroxide has been found effective⁹¹ Because of prolonged penicillin concentrations in the blood following this method of oral administration, it may have some prophylactic value

The advantages of giving penicillin by mouth include ease of administration and avoidance of hospitalization, with its attendant economic burden Relatively crude or impure penicillin would presumably be satisfactory Therapeutically effective blood levels can be maintained by several of the

above methods of administration, but the dosage must be markedly increased, as much as five times the intramuscular dose has been found necessary when the drug is given by mouth. Penicillin has also been administered by rectal suppository.⁹²

Penicillin in Early Syphilis

Various schedules of treatment were assigned by the Penicillin Panel of the Subcommittee on Venereal Diseases, Division of Medical Sciences, National Research Council.⁹³ It was quickly found that doses smaller than 1,200,000 units were entirely unsatisfactory, either alone or combined with arsenotherapy. Although lesions healed rapidly and positive dark-field examinations became negative, relapse was the rule. This emphasizes the importance of careful scrutiny for hidden early syphilis in all patients with gonorrhea treated with penicillin. Cases of secondary syphilis developing in such patients still continue to be reported from time to time.^{94, 95} The appearance of syphilis is merely delayed by the doses used for gonorrhea.

The time-dose relations of penicillin therapy probably require more study than does any other phase of this treatment problem. A trial of ten different regimens has been reported by McDermott, Benoit and DuBois.⁹⁶ Their observations suggested that only short periods of penicillin action are necessary for the immediate destruction of large numbers of the organisms, but that prolonged penicillin action is necessary for cure. Analysis of the various treatment programs under investigation showed that the frequency and size of the separate doses determined the total period of time during which effective concentrations of penicillin were present in the serum. It is apparently not the production of multiple peaks of high concentrations of penicillin but the length of the action at low concentrations that is the important factor. The maximum number of hours of efficient blood-level concentration appears to be obtained by a dosage of 25,000 units intramuscularly every two hours for ten days. It is to be hoped that some of the means of prolonging the action of the drug be discovered whereby a dosage schedule of one or two injections daily will produce satisfactory blood levels for the entire twenty-four hours.

The final evaluation of the ideal penicillin dosage for the treatment of early syphilis must await a prolonged period of study. Obviously, it is impossible to prove at this time that the penicillin programs suggested are superior to those already under investigation. Since, however, it appears that the length of time of penicillin action is the most important factor in the success of a given regimen, it is possible that a consideration of this time factor would help to limit the number of plans for study to those with the most promise.

Although arbitrary schedules at first suggested that a dosage of 1,200,000 units of penicillin was

satisfactory for the treatment of early syphilis, evidence is accumulating that much more than this may be necessary.^{98, 97} The total dosage recommended for treatment of early syphilis in the United States Army⁹⁸ over a year ago was 2,400,000 units. The Navy⁹⁹ recommends a similar dosage in seven and a half days. Even with this amount, some observers¹⁰⁰ have noted a lower percentage of cures than might have been expected.

Early syphilis resistant to arsenic and bismuth has been found to respond satisfactorily to penicillin. A group of 6 cases of the notoriously resistant psoriasiform secondary syphilis was shown to respond to varying doses of penicillin.¹⁰¹ Some patients required more than one course of penicillin. There is another case on record in which the patient still had dark-field-positive lesions after two and a half years of standard chemotherapy (irregularly administered).¹⁰² Ten weeks of combined bismuth and arsenotherapy then failed. Complete healing was obtained nineteen days after the injection of 1,200,000 units of penicillin within a period of four days.

Penicillin in Late Syphilis

The individualization that the treatment of late syphilis requires makes statistical evaluation extremely difficult. Material from the University of Pennsylvania¹⁰³ graphically illustrates that penicillin alone in the management of late syphilis, although of tremendous import, is probably not the ultimate answer. The combination of penicillin with arsenic and with fever therapy may well be of still greater value. The data indicate clearly that penicillin is an effective therapeutic agent in the treatment of late syphilis. Doses seldom exceeded 2,400,000 units, although some cases required re-treatment.

The United States Navy⁹⁹ dosage for latent syphilis is 4,000,000 units in twelve and a half days.

Congenital Syphilis

A preliminary report of the results of penicillin therapy in the treatment of 69 infants with early congenital syphilis showed in general a gratifying immediate response.¹⁰⁴ The dosage used consisted of 16,000 to 32,000 units of penicillin per kilogram of body weight, given in sixty doses over a period of seven and a half days. Five patients died during or soon after treatment, but whether these deaths were due to penicillin or to syphilis is not known. Serologic relapse occurred in 5 cases, and clinical relapse in 2. The results indicate that the present schedules are not entirely satisfactory with respect either to the total dose or to the time-dose relation. The authors recommend temporarily a total dose of 40,000 units per kilogram of body weight. More encouraging results have also been reported.¹⁰⁰

Neurosyphilis

There is disagreement as to the amount of pen-

cillin that will reach the cerebrospinal fluid after administration by parenteral routes^{105 106} Nevertheless, its effectiveness in various types of neurosyphilis seems established

Nelson and Duncan¹⁰⁷ treated 10 patients with acute syphilitic meningitis with penicillin. Four million units was given over a period of seven and a half to eleven days, and the immediate results were excellent from both clinical and laboratory standpoints. There was no evidence of clinical relapse in any patient, although one showed relapse in the spinal-fluid findings after six months. Intrathecal administration was found unnecessary.

The University of Pennsylvania group¹⁰⁸ found that practically all forms of neurosyphilis showed an encouraging response to penicillin therapy. A subsequent report on 89 of their cases stated that improvement in the blood serologic reactions in neurosyphilis and an even greater effect on the elements of the spinal fluid apparently continued for as long as four months after an eight-day course of treatment¹⁰⁹. Both the dosage and the length of treatment were found important in the results. The responses were obtained when the length of treatment was increased. Better ones were obtained from high doses than from low, — 4,000,000 units against 1,200,000 units, — and the best result followed a high dose given in two parts. Rose¹⁰⁹ combined intramuscular penicillin with fever therapy and reported encouraging results. A smaller group of patients was treated by Goldman¹¹⁰ with a combination of spinal and intramuscular penicillin or fever therapy and intramuscular penicillin; the early results were extremely favorable. The spinal nerve-root pains of tabes dorsalis were apparently rapidly relieved by the intraspinal administration of penicillin. Further work with the subarachnoid administration of penicillin indicates that this method entails considerable danger but holds promise^{111, 112}.

The present routine of treatment employed in the Navy⁹⁹ involves the administration of 8,000,000 units of penicillin in twenty-five days for the treatment of syphilis of the central nervous system, followed by ten courses of artificial fever accompanied by ten intravenous injections of penicillin, each of 60,000 units.

It has been found that penicillin does not suppress the fever or parasite count of active inoculated malaria, and that when given before or at the time of the malaria inoculation it does not prevent or postpone the development of fever and parasitemia¹¹³. Obviously, there should therefore be no contraindication to the use of penicillin before, during or after malaria.

Penicillin Reactions

Penicillin reactions in the treatment of syphilis, although minor, are not negligible. The Herxheimer reaction may occur, and in cases of late syphilis

such a focal reaction in a vital structure may be grave. Consequently, half the customary dose on the first day or even the second day may be advisable in many cases. This reduction should be compensated by a prolongation of the course.

Urticaria,¹¹⁴ some transient gastrointestinal reactions and exfoliative dermatitis¹¹⁵ have been observed in patients previously intolerant to treatment.

Contact dermatitis from penicillin has been reported a number of times¹¹⁴⁻¹¹⁶. In one case,¹¹⁷ it could be proved that impurities were the offending agent. The possibility of penicillin in the role of a future sensitizing agent has also arisen¹¹⁸.

SUMMARY

Approximately 25 per cent less cases of syphilis of all varieties were reported in this country during the first half of the fiscal year of the United States Public Health Service. It is to be hoped that this means a lowered incidence as well as a more effective campaign for the control of this disease. The first mass civilian blood-testing program has been started in Alabama. This is the result of a law passed by the state legislature and will be of tremendous import if pursued on a nation-wide scale. It could easily be the one most important control measure ever employed. The value of educational programs for the general public is proving itself. The staggering burden of syphilis on the taxpayer is illustrated by the fact that the care of general paresis alone costs over \$11,000,000 annually, aside from the economic loss to the patients afflicted.

The problem of false-positive tests for syphilis continues to receive a great deal of attention. The effectiveness of rapid-treatment programs and of penicillin in the therapy of syphilis has made the problem of relapse versus reinfection an extremely intricate one. It seems generally agreed that all such cases should be considered treatment failures when assaying the value of new treatment programs.

More attention has apparently been directed in recent clinical reports toward neurosyphilis than to any other phase of the disease. Considerable new statistical data and several excellent reviews of neurosyphilis in all its varieties are available. Intensive-treatment schedules show encouraging results in neurosyphilis, although the time of observation for these patients is not long enough. The first survey of massive arsenotherapy on a comprehensive scale indicates that the good results reported earlier have been maintained. Hemorrhagic encephalitis continues to be a most disturbing complication. More reactions are being observed from the use of Mapharsen, especially blood dyscrasias.

Penicillin is assuming an ever greater importance in the treatment of syphilis. Investigative studies are mushrooming in all directions in attempts to increase the effectiveness and to prolong the action time of this drug. Some investigators have raised the question whether pure penicillin itself is the ac-

tive agent in the treatment of syphilis. Resistant strains of *Treponema pallidum* have been developed experimentally. Much work has been done with the oral administration of penicillin with encouraging results. So long as hospitalization is required, with its attendant cost and increased burden on hospital facilities, the use of this drug will be somewhat limited. The optimal dose of penicillin in the treatment of syphilis is yet to be determined, and the time-dose relation is not properly understood. Present indications are that more prolonged administration will be necessary. The combination of penicillin with arsenotherapy has been producing most promising results. Reactions to penicillin continue to be comparatively insignificant.

As a brief statement of the situation, it may be said that penicillin is as yet incompletely analyzed and poorly understood. It seems to be an effective therapeutic agent in the treatment of syphilis, with less reaction than is caused by any previous drug. It cannot be too strongly emphasized that penicillin must continue to be regarded as purely an experimental drug in the treatment of syphilis, and that a minimum of ten to twenty years must elapse before its true value can be accurately assayed. Every serious investigator has stressed this point, and editorial comment has repeatedly emphasized it. One might say that patients treated with penicillin should be followed much more closely and over a greater period of years than ever before. It is to be hoped that military personnel will be included in this careful follow-up program.

CASE 32111

PRESENTATION OF CASE

A nine-year-old Negro girl was admitted to the hospital because of cervical and axillary lymphadenopathy.

The patient had had no chills, night sweats, joint pain, nocturia, anorexia or upper respiratory infection. The swelling of the lymph nodes had been noted four weeks before entry. She had not seemed ill and had gained weight during the month previous to admission. The teeth were in poor condition and had caused some pain for a three-week period before admission. A child with whom the patient had played two weeks before admission had developed swollen lymph nodes and fever, which subsided in one week. The patient developed fever two days before admission.

The past history was negative except for pertussis.

Physical examination revealed a well developed and well nourished, co-operative child, who did not appear ill. The skin was hot and dry. The cervical, posterior auricular, occipital, supraclavicular, epitrochlear, axillary and inguinal lymph nodes were enlarged, soft, nontender, movable and discrete, the nodes averaged 1.5 to 2 cm in diameter, except for the left supraclavicular node, which measured 4 by 3 cm. The pupils, eyegrounds, ears and nose were normal. The pharynx was slightly congested. The tonsils were not markedly enlarged. The teeth were carious. The neck was not stiff. The heart was not enlarged. A soft systolic murmur

was heard in the left third interspace and was not transmitted. The lungs were clear. The edge of the liver was palpable at the right costal margin. The spleen was palpated one fingerbreadth below the left costal margin. The common peroneal reflex and the signs of Chvostek and Trousseau were elicited.

The temperature was 103°F, the pulse 96, and the respirations 22. The blood pressure was 110 systolic, 70 diastolic.

The red-cell count was 4,200,000, with 8.6 gm of hemoglobin. The white-cell count was 22,000, with 83 per cent neutrophils. No malarial parasites were seen on smear. The urine was yellow, slightly cloudy and acid, with a specific gravity of 1.020 and a +++ test for albumin. The urinary sediment contained 8 to 10 white cells, no red cells and a rare cast per high-power field. The nonprotein nitrogen was 21 mg per 100 cc, and the serum protein 7.8 gm, with 3.0 gm of albumin and 4.8 gm of globulin. The serum calcium was 6.2 mg per 100 cc, the phosphorus 3.0 mg, and the alkaline phosphatase 8.4 Bodansky units. The serum sodium was 147.5 milliequiv per liter, the chloride 102 milliequiv, and the carbon dioxide content 27.7 milliequiv. The serum potassium was 4.9 gm per 100 cc, and the cholesterol 114 mg. Tests for heterophile and brucella agglutinins were negative. A tuberculin test was negative in a dilution of 1:1000. The Frei test was negative. The sedimentation rate was 0.9 mm per minute (Rourke-Ernstene method). Soon after admission one blood culture showed alpha-hemolytic streptococci, and another, nonhemolytic streptococci. Several others were negative.

An x-ray film of the chest showed a diffuse increase of all markings throughout both lung fields and a few nodular densities in both hilar shadows, more clearly seen on the right than on the left. An x-ray film of the abdomen showed some enlargement of the spleen, but no enlargement of the liver and no abnormal masses. A film of the skull was negative, and one of the teeth showed marked apical absorption about retained deciduous root fragments in the region of the second right molar area. The skeleton was not remarkable. An intravenous pyelogram revealed that the right kidney was normal.

tive agent in the treatment of syphilis. Resistant strains of *Treponema pallidum* have been developed experimentally. Much work has been done with the oral administration of penicillin with encouraging results. So long as hospitalization is required, with its attendant cost and increased burden on hospital facilities, the use of this drug will be somewhat limited. The optimal dose of penicillin in the treatment of syphilis is yet to be determined, and the time-dose relation is not properly understood. Present indications are that more prolonged administration will be necessary. The combination of penicillin with arsenotherapy has been producing most promising results. Reactions to penicillin continue to be comparatively insignificant.

As a brief statement of the situation, it may be said that penicillin is as yet incompletely analyzed and poorly understood. It seems to be an effective therapeutic agent in the treatment of syphilis, with less reaction than is caused by any previous drug. It cannot be too strongly emphasized that penicillin must continue to be regarded as purely an experimental drug in the treatment of syphilis, and that a minimum of ten to twenty years must elapse before its true value can be accurately assayed. Every serious investigator has stressed this point, and editorial comment has repeatedly emphasized it. One might say that patients treated with penicillin should be followed much more closely and over a greater period of years than ever before. It is to be hoped that military personnel will be included in this careful follow-up program.

of military tuberculosis. I believe much of the information recorded must have been obtained by fluoroscopy since I cannot see much of anything in these two films. The films do not suggest a pericardial effusion, but I suppose that that is a possibility. There is dullness anterior to the heart in the lateral view, suggesting a mediastinal mass.

DR KLEMPERER: What do you think this mass is?

DR HOLMES: It could be a mediastinal tumor—a Hodgkin's type of lymphoma or a large thymoma.

DR KLEMPERER: This comes as a surprise. Nevertheless, these x-ray films rule out military tuberculosis.

In regard to infection, subacute bacterial endocarditis is suggested by the two positive blood cultures, possibly by the diastolic murmur, which was heard at one time and by the enlargement of the spleen. If this child's death had been due to subacute bacterial endocarditis, however, I should have expected more evidence of a progressive valvular lesion and probably embolic phenomena. The kidney lesion does not resemble the embolic nephritis seen in subacute bacterial endocarditis. Because the hematuria was preceded by albuminuria, subacute bacterial endocarditis might have been present but I do not believe that it was the primary cause of this child's illness. After ruling out infection as the primary disease we must consider a group of diseases that, so far as we know, are not infectious in origin but are capable of involving various systems of the body. Among these the likeliest are lymphoma, sarcoid and possibly periarteritis nodosa and disseminated lupus erythematosus.

Hodgkin's disease is strongly suggested by the onset with adenopathy. We do not know about any constitutional symptoms that might have preceded the appearance of the enlarged lymph nodes. It is also suggested by the size and the distribution of the lymph nodes. Hodgkin's disease may be acute and lead to death in a single attack, with high fever. What bothers me about Hodgkin's disease in this patient is first, the kind of renal involvement. I have never seen or heard of a patient with lymphoma in whom albuminuria and subsequent hematuria were the outstanding symptoms and signs and whose death was caused by renal failure. The next point that I believe almost rules out this diagnosis is that the biopsy did not show any specific lesion. The surgeon must have removed an obviously enlarged node, and if it was Hodgkin's disease it should have been demonstrated in the excised specimen.

DR HOLMES: I hope that I have not been misleading you. As I look through the record I find that a film taken at one time showed an apparently normal-sized heart shadow. That makes my interpretation of tumor most unlikely. A tumor would not appear in such a short period of time. In other words, the mass probably represents an enlargement of the heart shadow.

DR KLEMPERER: I shall also consider lymphoma unlikely for the reasons stated.

I then come to sarcoid. This is suggested by the symptoms and by the lymphadenopathy that initiated the illness. We know that sarcoid can involve every organ in the body. Cardiac involvement, pulmonary involvement and, quite frequently, renal involvement are known to occur. I have not seen nor to my knowledge has a case been reported in which renal involvement dominated the picture. The main reason why I want to throw out sarcoid is that the patient was much too sick. Sarcoid usually runs a long course and seldom causes a white-cell count as high as this was. Furthermore, one of the arguments that I used against Hodgkin's disease or lymphoma in general may be applied against the diagnosis of sarcoid, namely that the biopsy was negative.

Periarteritis nodosa is the next consideration. I should like to think of this lesion as a more or less nonspecific tissue reaction that is not necessarily a disease entity. Dr Francis M. Rackemann frequently stresses this point. Such a tissue reaction is seen in various stages of sensitivity and may also be seen in disseminated lupus. It should be called a disease entity only in the presence of a clear-cut clinical picture. In the absence of asthma, joint pains and eosinophilia, this diagnosis seems untenable. The renal involvement is not characteristic, and I am at a loss to explain the adenopathy on the basis of periarteritis nodosa. I shall rule it out.

That leaves me with lupus erythematosus as a final possibility. There are several factors against it. Lupus erythematosus usually affects young adults, although it is known that it rarely occurs in children. We have seen it in a girl before the onset of menstruation, and similar cases have been described in the literature. The age, therefore, does not permit me to rule out lupus. The patient had a white-cell count of 22,000. One frequently hears the statement that lupus should always be accompanied by leukopenia. That is not true. Frequently the white-cell count is below 5000, but I have seen several cases with a white-cell count as high as this, and a number of cases are cited in the literature. The onset of the disease is likewise quite atypical. Usually the initial symptoms in lupus are skin rash, joint pains and constitutional symptoms. I have not seen or heard of a case of lupus that started with adenopathy, but I question the history. I wonder if the patient might have run a fever long before she came to the hospital. On admission she had renal involvement with a low calcium and tetany that must have existed for some time, and yet she had no complaints. I wonder if they were missed. Adenopathy is quite frequent in lupus, about half the cases show it, at times to a fairly marked degree. The renal involvement in this patient is quite characteristic, beginning with

in size, shape and position. The left kidney was not well visualized at any time. The intravenous dye appeared promptly in good concentration, outlining normal urinary passages.

During the patient's hospital course the temperature varied from 98 to 106°F, usually running between 100 and 102°. Soon after admission a lumbar puncture showed clear fluid under an initial pressure equivalent to 300 mm of water, the cell count and chemical constituents were normal. The patient was given sulfadiazine, 5 gm every four hours, and penicillin, 12,000 units every three hours. On the third hospital day, since the blood sulfadiazine level had risen to 74 mg per 100 cc and sulfadiazine crystals had appeared in the urine, the drug was discontinued. A lymph-node biopsy showed hyperplasia. Albuminuria persisted, with 10 to 15 white cells, numerous red cells and many hyaline, granular and red-cell casts per high-power field. On the twelfth hospital day a chest film showed enlargement of the heart to the left and right, with pulmonary edema. On physical examination there were no rales. The pulse rate was 120, the blood pressure was 128 systolic, 76 diastolic. The heart sounds were of poor quality. There was a gallop rhythm, with short diastole, and a soft mid-diastolic murmur at the mitral area. The liver was enlarged three fingerbreadths below the right costal margin. The abdomen was doughy and distended, apparently containing a small amount of fluid. An electrocardiogram on the same day showed normal rhythm, with a rate of 110. There was slight right-axis deviation. The PR interval was 0.12 second. There was slight inversion of T₁, T₂, and T₃ were upright, TCF₂ was moderately inverted, TCF₄ was inverted, and TCF₅ was flat. The patient was rapidly digitalized, and the heart sounds improved. The blood pressure was 110 systolic, 50 diastolic. The nonprotein nitrogen was 31 mg per 100 cc, the serum phosphorus 4.1 mg, the alkaline phosphatase 2.3 Bodansky units, and the serum protein 8.1 gm per 100 cc.

A chest film taken on the seventeenth hospital day revealed marked enlargement of the heart, which showed small, rapid, but definitely perceptible pulsations. The pulmonary and hilar vessels were considerably engorged. There was a definite, small area of localized density in the right chest laterally, above the diaphragm. There was also hazy increased density throughout both lungs. The patient was drowsy and irritable. There was no dyspnea or orthopnea. The heart sounds were forceful and rather metallic in character. There was a precordial systolic murmur. The lungs were dull at the bases, without rales. The abdomen was distended. The liver edge was tender and 4 cm below the right costal margin in the midclavicular line. The spleen was palpable 2 cm below the left costal margin. There was no edema of the sacrum or legs. The eyelids were slightly puffy. There was

no skin rash. At that time the urine was smoky and alkaline, had a specific gravity of 1.020 and gave a ++++ test for albumin. The sediment contained 20 to 30 white cells, numerous red cells and frequent granular casts per high-power field. The eyegrounds for the first time showed hyperemic choked disks, more marked on the right than on the left. There was no retinal hemorrhage or scarring.

A chest film taken on the twenty-second hospital day showed no change in the size of the heart but some decrease in the engorgement of the hilar and pulmonary vessels. The nonprotein nitrogen was 29 mg per 100 cc, the serum protein 7.0 gm, the cholesterol 147 mg, and the potassium 5.2 miliequiv per liter. The prothrombin time was 26 seconds (normal, 18 seconds).

Penicillin was discontinued on the thirty-third hospital day. The abdomen became markedly distended, and generalized pitting edema appeared. The blood pressure was 82 systolic, 35 diastolic. The heart sounds were of poor quality. Slow epistaxis occurred. The respirations were shallow, and the diaphragm was high. The breath sounds were coarse, especially at the bases, but there were no rales. The nonprotein nitrogen rose to 70 mg per 100 cc.

On the thirty-sixth hospital day the respirations became more rapid. The pulse was full and strong but paradoxical. The patient was put in an oxygen tent and was reasonably comfortable lying flat. Venous distention was not marked. Edema of the legs increased. Rales appeared at the lung bases for the first time. Dyspnea and a hacking cough were troublesome. After a period of irregular respirations the patient expired, on the thirty-ninth day.

DIFFERENTIAL DIAGNOSIS

DR FRIEDRICH W KLEMPERER. In summary, we are dealing with a nine-year-old colored girl who, within five weeks, developed adenopathy, renal involvement, cardiac involvement and probably pulmonary involvement and died. This course suggests infection, but such diseases as infectious mononucleosis, brucellosis or lymphogranuloma inguinale were ruled out by the serologic and skin tests. I see no mention of a Hinton test, but aside from the adenopathy, which in this case would not be characteristic, I see nothing to suggest syphilis. There was a negative tuberculin test. This does not rule out tuberculosis because in miliary and rapidly progressing tuberculosis the tuberculin test may be negative. I do not believe, however, that this was tuberculosis, particularly because of the character and distribution of the lymphadenopathy, which was not suggestive of this disease. If this had been miliary tuberculosis I should have expected a different description of the x-ray films.

I should like to see the x-ray films. Is there anything to suggest a miliary process in the lungs?

DR GEORGE W HOLMES. There is no evidence

cavity. For a girl as small as this patient was, that is significant effusion. Since the fluid was perfectly clear, with no strands of fibrin, it cannot be said that she had a pericarditis. The heart weighed 155 gm, perhaps slightly enlarged. The pair of kidneys, in contrast, weighed 300 gm, in other words, there was marked enlargement. The kidneys microscopically showed a diffuse glomerulonephritis, with both intracapillary and capsular changes, including many epithelial crescents. There were secondary although still fairly early degenerative changes in the tubules. We saw nothing in the kidneys to suggest sulfonamide damage. The lymph nodes at autopsy showed nothing more spectacular than the one that was biopsied. The thymus was extremely large, weighing 50 gm, which is nearly twice the normal size for a child of this age, and perhaps that is what Dr Holmes pointed out.

Our anatomical diagnosis was subacute glomerulonephritis, and we have no explanation for the enlarged lymph nodes. We found none of the usual findings at autopsy that would help to confirm a diagnosis of lupus erythematosus. The lymph-node picture in that disease is not specific, but there are likely to be a number of rather characteristic changes, which were not present here. She had effusions in various serous cavities but no inflammatory changes in any of them. A diffuse glomerulonephritis is occasionally seen in characteristic cases of lupus, but it is not the usual lesion; ordinarily one finds either focal glomerulonephritis or the so-called "wire-loop" lesion described by Baehr, Klemperer and Schiffrin*. I can neither confirm nor disprove the diagnosis of lupus erythematosus. It remains a possibility. Certainly, the anatomical diagnosis of subacute glomerulonephritis does not explain a great deal of the picture.

CASE 32112

PRESENTATION OF CASE

A forty-six-year-old woman, a spinner in a textile mill, was admitted to the hospital for pain in the right chest.

Three years prior to admission the patient developed an annoying and slightly painful sensation in the right posterior axillary line overlying the tenth and eleventh ribs. She likened the sensation to "numerous mosquito bites." Her physician performed several thoracenteses, with negative results. No x-ray studies were done. The episode subsided after three weeks and did not recur. Two years later, one year before admission, a routine chest film taken at the mill where she was employed was reported as normal. At about that time she began to have attacks of moderately severe pain

in the same previously affected area of the right chest. The pain was steady, aggravated by inspiration and partially relieved by lying down. She had frequently been awakened by it but had never had to take medicine for relief. Each attack lasted from one to three weeks. At first they occurred every two to three months, but as the year progressed the intervals between attacks were gradually lessened until the pain was almost constant. There had been no cough, sputum, hemoptysis, night sweats or known exposure to tuberculosis. She had lost 6 pounds in the six months prior to admission. One month before admission her physician obtained a chest film, which was reported to have shown a "large spot in the middle lobe."

At the age of eight years a mass in the left submandibular region ruptured and drained spontaneously; there were no sequelae.

On physical examination there was slightly increased vocal fremitus over the right upper chest and questionable increased whispered voice sounds in the same area. Tactile fremitus was normal, as were percussion and auscultation. There was a well healed scar 5 cm long over the left submandibular region.

The temperature was 98°F, the pulse 85, and the respirations 20. The blood pressure was 145 systolic, 95 diastolic.

The red-cell count was 4,250,000, with 13 gm of hemoglobin. The white-cell count was 11,200, with 82 per cent neutrophils, 14 per cent lymphocytes and 4 per cent monocytes. The urine was normal. The serum protein was 6.2 gm per 100 cc. An x-ray film of the chest revealed an area of increased density, with superimposed linear areas of greater density, in the posterolateral portion of the right lower lobe. The right hilus was somewhat depressed. The remaining lung fields appeared clear. The diaphragm moved freely and equally. The costophrenic sinuses were flattened. The heart, aorta and upper mediastinum were within normal limits (Fig 1).

On the second day after admission bronchoscopy was performed. Just beyond the upper lobe opening, the lumen of the right bronchus was markedly narrowed by a concentric constriction. No tumor mass was seen. The mucous membrane was normal. The bronchoscope could not be passed below this level. Smooth forceps were passed beyond, but no palpable outcropping was encountered.

An operation was performed on the seventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR MILES P. BAKER. The chief considerations in this case seem to be the etiology of the constriction found in the right main bronchus and the nature of the process demonstrated by x-ray in the right lower lobe. I think that I had better ask to see the films now.

*Baehr G., Klemperer P. and Schiffrin A. Diffuse disease of peripheral circulation usually associated with lupus erythematosus and endocarditis. *Tr. A. Am. Physicians* 1: 139-155, 1935.

albuminuria and leading to hematuria and eventual renal failure

Cardiac failure can take several forms in lupus erythematosus. The picture given here is quite consistent with that diagnosis. One naturally thinks of pericarditis. It is stated in the record that by fluoroscopy there were definite pulsations but that they were weak. The electrocardiographic changes may be explained on the basis of pericarditis or myocardial involvement, but toward the end there was a paradoxical pulse, and if this observation was correct, it is strongly in favor of a diagnosis of lupus erythematosus, which so frequently is complicated by serositis. The involvement of the heart might have been on the basis of the diffuse myocardial involvement that is occasionally seen in lupus. A mid-diastolic murmur was heard at one time, but a later report says that a systolic murmur was heard, which means to me that only a systolic murmur was heard, so we are not certain whether the patient had mitral involvement. If the patient did have mitral involvement, I should interpret it on the basis of Libman-Sacks endocarditis. We know that this endocarditis is frequently complicated by bacterial invasion, which may have been the case in this patient, who showed positive blood cultures on two occasions.

Whether there was involvement of the lungs, I am not quite certain from the clinical record. One quite frequently sees a picture that resembles a shifting bronchopneumonia in lupus, and some of the x-ray findings, that is, the increased density, may be explained on that basis.

I believe that the abnormalities of the blood constituents are explained on the basis of the renal lesion, particularly the low calcium, which led to tetany. A high globulin is not infrequent in lupus, and in some series it has been found almost in all cases. We have seen it in some.

In reading this record one gets the impression that the child was not particularly ill when she came to the hospital, but from the time that she was given sulfonamides, her disease rapidly progressed to death. I do not know why the child was given sulfonamides. So long as a diagnosis of lupus is a possibility, I think that sulfonamides should be withheld, because in our experience the administration of sulfonamides in patients with lupus has produced severe exacerbations. So, this exacerbation following the administration of sulfonamides may also be interpreted in favor of the diagnosis of lupus. Although I believe that the child's age and the absence of skin lesions and joint pains argue somewhat against the diagnosis of lupus erythematosus, I can think of no other disease entity that fits this picture better, and I shall therefore offer it as my diagnosis.

DR TRACY B MALLORY Are there any comments from the Pediatric Service?

DR JOHN D CRAWFORD My first comment is

that the history is accurate. It was rechecked several times, and on several occasions I talked to the patient's mother, who is a very intelligent person.

The patient was first seen in the Surgical Service of the Out Patient Department because of large nodes in the neck, from there she was referred to the X-ray Department, and she finally came to us by way of the Emergency Ward. We did not consider that she was seriously sick on admission, but during the first forty-eight hours in the hospital she ran a spiking temperature, which reached 106°F on two occasions. It was decided, more or less in desperation, to use sulfonamides and penicillin, since the predominance of polymorphonuclear leukocytes in the blood smear suggested an infection. We were not happy about the use of sulfonamides in a patient whose etiologic diagnosis was not established.

Another point that I want to make concerns this child's x-ray studies. The first film, taken when she was seen in the Surgical Service of the Out Patient Department, showed a normal heart with enlarged nodes. The second film, taken four days later when she was admitted to the ward, still did not show an enlarged heart. About ten days after that one of the house officers thought that he heard a murmur, and recommended another x-ray film of the chest. She was sent to the X-ray Department and they reported that the child had acute cardiac failure and pulmonary edema. A greatly enlarged cardiac shadow with pulmonary congestion persisted, despite therapy, from that time until death. We suspected pericarditis in addition, but we thought, since the pulsations showed through every time she was fluoroscoped and since clinically there was no cardiac embarrassment, that the effusion was not great in amount.

CLINICAL DIAGNOSES

Acute nephritis
Myocarditis
Pericardial effusion

DR KLEMPERER'S DIAGNOSIS

Lupus erythematosus disseminatus

ANATOMICAL DIAGNOSES

Subacute glomerulonephritis
Pulmonary congestion and edema
Anasarca
Lymphoid hyperplasia, generalized
Hyperplasia of thymus

PATHOLOGICAL DISCUSSION

DR MALLORY Dr Klemperer has shown the discretion to pick a diagnosis that I cannot refute. The significant autopsy findings were the generalized lymph-node enlargement noted clinically and the generalized edema, with about 1000 cc of fluid in the peritoneal cavity and 80 cc in the pericardial

chus One of the causes of bronchostenosis of a fibrostenotic type is, as you know, syphilis. It is of uncommon occurrence and has become even less frequent as gummas and tertiary syphilis are less often seen. I have never seen a proved case. I am told that syphilis of the tracheobronchial tree is likelier to involve the trachea and its bifurcation than the main bronchus, as here. It may produce a constricting obstruction, such as this, but we have no corroborative evidence for such a diagnosis in this case, and there is no other evidence of tertiary syphilis.

I shall mention briefly two other possibilities that may occur as causes of such stenosis. One is actinomycosis, but this too is likelier to involve the trachea as an obstructive lesion. Rhinoscleroma is another condition mentioned in the books, associated with similar changes in the larynx, forming multiple hard annular lesions and sometimes a funnel-shaped stenosis of the trachea and major bronchi. The peribronchial processes that cause marked stenosis usually involve the small branches of the bronchi, not a major bronchus, such as we have involved here. I believe that we can dismiss them from consideration as we have these rarer causes of bronchostenosis.

We come to tuberculosis as a cause of what the bronchoscopist found in this patient's bronchus. A great deal was learned about tuberculous lesions of the trachea and large bronchi in the years shortly before the war as a result of systematic bronchoscopy in many patients with pulmonary tuberculosis in sanatoriums and elsewhere. These observations have demonstrated that a fibrostenotic obstruction may be the end result of spontaneous healing of a tuberculous bronchitis that originally took the form of an ulcerated granulomatous lesion. It takes a long time for healing to take place and for such a stenosis to develop. This type of stenotic obstruction has been found with minimal or no pulmonary tuberculosis, although it is not apparently a common occurrence, and such patients not infrequently develop frank pulmonary tuberculosis under observation.

The origin of bronchial tuberculosis may be extension from peribronchial caseous tuberculous lymph nodes but is much more frequently the result of extension from primary pulmonary disease, usually in the upper lobe but occasionally in the lower lobe. So, although we may say that this obstruction is compatible in appearance with an old tuberculous etiology, we are drawing a rather long bow in assuming that the stenosis was both of many years' standing, possibly dating from adolescence, and due to involvement of the bronchus by tuberculous infection that developed in a juxtaposed caseous lymph node. This happens in children but is not so likely to be seen in adults. This certainly is not the usual story in cases in which fibrostenotic lesions have been observed by bron-

choscopy. Much oftener than not such patients have x-ray evidence of active pulmonary tuberculosis or at least an arrested pulmonary tuberculous lesion. It may not be too farfetched, however, to assume that we are dealing with an old tuberculous lesion on the basis of symptomatology, because symptoms may not arise in these patients with bronchostenosis until they develop infection distal to the constriction—the old story of bronchial obstruction and damage to bronchi, infection, bronchiectasis, abscess and recurrent pneumonitis, usually in a lower lobe. It is interesting to remember that syphilitic bronchial obstruction in the days when it was more frequently seen and reported did not necessarily give rise to bronchiectasis, even though the degree of constriction was marked and oftener than not bronchiectatic changes were found. Unless there is a wheezy dyspnea, symptoms are likeliest to develop in the presence of such bronchial obstruction only when the patient develops infection distal to the obstruction. That is what I think has probably happened in this woman. That is more probably a cause for her pleuritic pain than an entirely different process, such as a tumor in the right lower lobe, something that we cannot absolutely rule out, but I think that it is less likely than infection.

There is no question about the wisdom of surgery. This woman had an obstructive process in the lower lobe and symptoms referred thereto. I believe that the pathologist may not have found any confirmatory evidence of tuberculosis to account for this bronchostenosis. The shadow that we see by x-ray probably does not represent an abscess, but rather an area of pneumonitis. It is quite likely that distal to such a constriction as this woman had there was more bronchiectasis than one might expect in the absence of fever and cough.

DR DONALD S KING It comes down to a matter of x-ray interpretation. I assume that the X-ray Department was not convinced of tumor in this case.

DR SCHULZ But I do not know how one could be certain that there was not a tumor occluding a small bronchus, behind which the findings seen in the chest film had taken place.

DR KING It is hard to hitch up tumor with the narrow bronchus.

DR TRACY B MALLORY I am sorry that Dr Sweet is not here to discuss this case, because I understand that there was a lively argument whether or not the patient should be submitted to surgery. Perhaps you can tell us about that, Dr Miller.

DR CARROLL C MILLER Dr Sweet went into the problem with a strong conviction of the advisability of operation and the likelihood of finding cancer. He believed, as Dr Schulz has intimated, that the x-ray appearance was more like that of carcinoma than of the other conditions that Dr Baker has mentioned. He is in favor of exploratory

DR MILFORD D SCHULZ Here is the area in question I do not believe that I can add anything to the written report The area lies laterally and somewhat posteriorly

DR BAKER Can you exclude pulmonary tuberculosis of the upper lobes?

DR SCHULZ Yes, except for evidence of an old healed primary lesion, which represents something long gone by

DR BAKER And it is not impressive There was no attempt made to determine the possibility of

lower lobe There are also recorded a childhood history of lymphadenitis of tuberculous origin, a constricting lesion in the right bronchus, an x-ray lesion in the right lower lobe, which we can see here in the lateral film, and a moderate degree of polymorphonuclear leukocytosis

The interesting negative facts are absence of cough, of sputum, at least of hemoptysis, of fever and of abnormal physical signs in the chest The last is not too extraordinary in the presence of bronchostenosis Some years ago Dr Frederick

FIGURE 1

obstructive emphysema, that is, no films were taken at expiration?

DR SCHULZ No I assume that the fluoroscopist who examined the chest was not impressed with any such possibility

DR BAKER There are a number of important positive facts in this case The first is the three-year story of pain in the right lower chest, which was first intermittent and then became constant and pleural in nature Presumably the patient presented physical signs three years previously that suggested to the attending physician that there was fluid at the right base These signs may of course have been due to atelectasis of the right

T Lord made the comment that with marked bronchostenosis, if there was a small persisting orifice, there might be a striking paucity of abnormal physical signs Moreover, there is no x-ray evidence of obstructive emphysema or of atelectasis We have no evidence of obstruction by a bronchiogenic carcinoma or by a so-called "benign adenoma" of the bronchus, which might have been suspected here, even in the absence of hemoptysis We have no information regarding the skin tuberculin test or the blood Hinton reaction, both of which might have had some significance if negative.

We come then to the differential diagnosis of this concentric obstruction in the right main bron-

PENICILLIN TREATMENT OF EMPYEMA

At a meeting of the New York Academy of Medicine in November, 1943, Tillett, Cambier and McCormack¹ reported on the treatment of 8 patients with pneumococcal empyema by repeated thoracenteses with aspirations and intrapleural injections of penicillin. In 7 of these patients the infection was eliminated by local treatment and no surgical drainage was required. The same authors² subsequently reported on 13 additional cases of pneumococcal empyema, all of which were successfully treated in a similar manner. In 20 of the 21 cases of pneumococcal empyema, these authors obtained recoveries without evidence of residual chronic infection and without thoracic deformity or detectable reduction in pulmonary function. In

14 of the cases a single series of local injections ranging from one to five doses, usually consisting of 30 000 to 50 000 units each given on alternate days proved successful. In 7 cases relapses of the infection occurred when the initial course of treatment was suspended, but reinstitution of local therapy with penicillin resulted in complete and permanent clearing of the infection in 6 of these cases. The single unsuccessful case was in a child two years old who was operated on after the first course of treatment was followed by a relapse. The general condition of all the patients improved before the exudate cleared. Complete clearing according to x-ray films required from three to nine weeks. The average time between the first and last thoracenteses was twenty-four days. Follow-up studies also revealed a return of the affected side to normal functional state and only a limited degree of pleural thickening remained.

There have been a number of subsequent reports on the use of penicillin in the treatment of pneumococcal and other types of empyema. The results obtained in a small series of cases at the Boston City Hospital, as well as an analysis of the cases collected from the literature will be presented in a forthcoming issue of the *Annals of Internal Medicine*.³

The reported cases fall into three general groups. The first consists of 128 cases of empyema that occurred as a complication of wounds and of operations on the lungs and pleura. The results in this group were difficult to evaluate because of the variety of underlying conditions and many complicating factors. Several authors, however, believed that intrapleural penicillin was of great help in the management of these cases and that such treatment obviated the necessity for secondary operations for drainage of the empyema in a number of cases.

The second group comprised 15 cases of putrid empyema. These cases, which are often due to mixed infections and are associated with other infectious processes in the lungs or elsewhere, are known to have a high mortality even under the best surgical management. Anaerobic streptococci and a variety of other organisms, some of which are resistant to penicillin, may be present. The use of intrapleural penicillin in these cases resulted in considerable im-

thoracotomy in cases in which there is so much doubt concerning the diagnosis. In addition to the x-ray appearance I think that the bronchoscopist's description is of importance, because we frequently do see cases of carcinoma in which there is constriction of the bronchus without obvious tumor in the lumen of the bronchial tree.

DR KING: That far away from the lesion?

DR MILLER: Yes. We have seen a process extending along the bronchial tree some distance away from the lesion seen by x-ray.

DR MALLORY: Will you tell us about the operative findings?

DR MILLER: On opening the chest there were no adhesions. There was a moderate-sized tumor, quite a bit larger than what was indicated by the x-ray films, in the lower lobe, involving the middle lobe and extending down the hilus, so that the bronchoscopist's findings were easily explained. There were also enlarged lymph nodes around the hilus. In the anterolateral inferior segment of the lower lobe there was a triangular area of induration that had a grayish color on its surface, with a purplish edge. This resembled an infarct. It was thought advisable to do a pneumonectomy rather than a lower and middle lobe lobectomy.

CLINICAL DIAGNOSIS

Carcinoma of lung

DR BAKER'S DIAGNOSES

Bronchial obstruction, due to healed tuberculosis of bronchus

Pneumonitis, right lower lobe

ANATOMICAL DIAGNOSES

Adenocarcinoma of lung, with metastases to hilar lymph nodes

Pulmonary infarcts, distal to tumor

PATHOLOGICAL DISCUSSION

DR MALLORY: The specimen we received at the laboratory was unusual and aroused our interest since none of us could remember having seen anything quite like it. The primary condition was a carcinoma arising in a relatively small bronchus, growing upward toward the hilus along the bronchi and constricting them by external pressure from outside. There was no outcropping in any of the major bronchi that the bronchoscopist could reach. I doubt that it would have been possible for him to take a biopsy, which would have helped settle the issue.

The unusual feature from our point of view was the presence of two foci of markedly increased density in the peripheral portions of the lower lobe. These were in contact with the pleural surfaces and were grossly and microscopically characteristic of old infarcts. It is, of course, of common occurrence to find bronchiectasis and various types of obstructive pneumonitis behind constricted bronchi, but one does not expect to find infarction. We believe that this was explained by the constrictive action of the tumor, which gradually surrounded the major vessels leading to the lower lobe and cut down the blood supply to such an extent that infarction developed. Possibly infection may have played a role, but the microscopical appearance does not particularly encourage the theory of septic infarction.

The tumor was quite well differentiated, obviously slowly growing and very scirrhous in type, I think that it was an adequate explanation of the symptomatology.

itself, although the world still has many more mouths to feed than it has food for, and the dislocations due to war appear to be succeeded by the dislocations due to peace, and now the time seems to have come to consider the righting of some of our older wrongs. A cataloguing of the penalties under which margarine must seek its market furnishes an amazing exhibit.

On the federal side there is a tax of 10 cents a pound on colored and $\frac{1}{4}$ cent a pound on uncolored margarine. The manufacturer of all margarine must pay an annual federal license fee of \$600. The wholesaler must pay an annual license tax of \$480 to handle colored margarine, and one of \$200 for uncolored margarine. The retailer of colored margarine must pay an annual license fee of \$48, and he who sells uncolored margarine, one of \$6. Public eating establishments, hospitals and charitable, religious and other institutions that serve margarine that they buy and color themselves must pay the yearly manufacturer's license fee of \$600, as well as an excise tax of 10 cents a pound.

So far as state penalties are concerned, nine states, including Connecticut, of the New England group, charge a manufacturer's license fee of \$1 to \$1000 yearly. Fourteen states, including Connecticut and Vermont, charge a wholesaler's license fee of \$1 to \$1000 yearly. Seven states charge an excise tax on all margarine of from 5 to 15 cents per pound. Twelve states, including Connecticut, Vermont and Massachusetts, charge a retailer's annual license fee of 50 cents to \$400. Twenty-four states, including Connecticut, Vermont, Massachusetts, New Hampshire and Maine, bar the sale of colored margarine.

This, if you please, is to stifle the distribution of a highly nutritious, fundamentally inexpensive article of food of which all or part of the ingredients are farm products of forty-four states and that should require no special legislative oversight except, perhaps, that it be served in public under its own name. Government strangles competition the life of trade, and the butter boys sit pretty!

MASSACHUSETTS MEDICAL SOCIETY DEATH

CHURCHILL — Frank S. Churchill, M.D., of Bass River, died February 27. He was in his eighty-second year.

Dr. Churchill received his degree from Harvard Medical School in 1890. Before moving here, he lived in Chicago, where he served as medical inspector on the Board of Health and as chief of staff, Children's Memorial Hospital. He was chairman of the children's section of the American Medical Association and also editor-in-chief of the *American Journal of Diseases of Children*. In 1917-1918, he was chief of medicine at Camp Devens Hospital. He was formerly a medical assistant at the Judge Baker Guidance Clinic, Boston. He was a former president of the American Pediatric Society.

YOUNG — J. Herbert Young, M.D., of Newton, died February 18. He was in his sixty-fourth year.

Dr. Young received his degree from Harvard Medical School in 1906. At the time of his retirement in 1941, he was consultant in pediatrics at the Massachusetts Eye and Ear Infirmary and New England Baptist Hospital, physician to Children's Medical Service, Massachusetts General Hospital, and physician and chief of the Department of Pediatrics, Cambridge Hospital. For many years he was an assistant in pediatrics at the Harvard Medical School. He was a diplomate of the American Board of Pediatrics and a member of the American Academy of Pediatrics and the New England Pediatric Society. He was a fellow of the American Medical Association.

His widow, a daughter and a son survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

BLOOD AND BLOOD DERIVATIVES PROGRAM

SURPLUS ARMY-NAVY PLASMA RECEIVED FROM AMERICAN RED CROSS

The Department of Public Health has begun operation of its blood and blood-derivatives program announced in the October 4, 1945, issue of the *Journal*. Collection of voluntary blood donations has been underway, the blood so collected being processed to liquid plasma and plasma fractions, in collaboration with Harvard Medical School pending completion of the Blood Processing Laboratory now under construction in Forest Hills.

The accumulation of an adequate supply of plasma fractions will be greatly facilitated by the recent release of a large supply of surplus Army-Navy dried plasma by the American Red Cross. This plasma is being returned to civilian use throughout the country, with state health departments acting as the distributing agencies.

The first Massachusetts allotment of 15,000 units has been received and will be ready for distribution on March 15, after it has been inspected and checked for condition of packages and date of expiration.

Following consultation with an Advisory Committee consisting of Dr. Elmer S. Bagnall, Dr. Charles A. Janeway, Dr. Charles C. Lund, Dr. Joseph F. Ross, Dr. Michael A. Tighe and Dr. Charles F. Wilinsky, the Department of Public Health has adopted a uniform general policy for handling the distribution of products derived from voluntary human blood donations. The regulations

provement in the general condition of the patients. Only 2 cases were reported as completely cured without surgical drainage, but several of the others were considered to be much better surgical risks as a result of the preliminary treatment with penicillin. Deaths were usually associated with other complicating conditions.

The remaining 236 cases were nonputrid empyemas that were not associated with wounds or operations on the thorax. More than half these cases were cured by aspiration and penicillin treatment without resort to operative drainage. The results reported by different observers vary widely. Several of them obtained results comparable to those of Tillett, whereas a few claimed that operation was necessary in every one of their cases. The type of material available to these workers may have accounted for the differences in the results obtained. It is apparent, however, that the enthusiasm with which the medical treatment was pursued varied considerably, as might be expected with any new form of therapy, and the results varied accordingly.

Jacobson⁴ in a recent report from a Navy hospital suggests that the recovery time in patients with empyema whom he treated was actually prolonged by the use of penicillin intrapleurally, although the initial response was good. He concluded that marked thickening of the pleura may follow this treatment and may give rise to deformity and to the impairment of pulmonary function. There is, however, little evidence to support this view. The experiences of Tillett and of the workers at the Boston City Hospital indicate that the time for complete recovery in cases of empyema was considerably shortened if operation was avoided. The final results with respect to impairment of pulmonary function and the residual pleural thickening, as revealed by follow-up x-ray examinations, were at least comparable to, if not better than, those obtained after operative drainage. Additional experience with the medical treatment will be necessary before the end results can be evaluated and compared with those obtained by early resort to surgery.

There can be little doubt in the minds of those who have followed any number of patients with empyema after they had been subjected to rib resection that the results leave much to be desired.

Secondary infection after operation is almost inevitable. Evidence of active infection may last for several weeks, and drainage from the wound may persist for several months before there is complete obliteration of the empyema cavity and healing of the external wound. Ugly scars and deformities of the chest are not infrequent. If a large proportion of cases of empyema can be cured by repeated aspirations and intrapleural penicillin without resort to operation, this method of treatment warrants a serious trial. The end results in terms of the total duration of illness until the cavity is obliterated and all evidence of infection subsides, as well as the residual thickening, the chest deformities and the impairment of pulmonary function, should be carefully assessed and compared with those of surgical drainage before final judgment is passed on the relative value of these forms of treatment.

A BREAK FOR MARGARINE?

DURING the war, when food rationing was in existence and the housewives of America were indoctrinated with the idea of marketing in terms of nutritional values, certain foodstuffs became popularized and were eventually accepted as adequate substitutes for more orthodox articles of diet. The soy bean, as a complete vegetable protein, became a naturalized citizen, oleomargarine, scorned for decades as a result of skilled propaganda on the part of the dairy interests, took its place nearly on a level with butter as a satisfactory table fat.

The *Journal*, in those sober days so recently left behind us, advocated the cause of margarine,* for despite its acceptance by the open-minded representatives of public opinion, this valuable and potentially inexpensive food still labored under the handicap of various discriminatory and thoroughly undemocratic acts of legislation. Our normal balance of supply and demand is gradually righting

MODERN TRENDS IN LOCAL
BOARDS OF HEALTH

To the Editor Many of the board-of-health members and their agents do not appear to be aware of the current trends in the thinking and planning that is going on for local health work. It is an accepted and well established principle that government is responsible for the health of the people and that certain basic health services should be rendered to all communities, large or small, through a governmental agency.

Two books that have recently appeared, both published by the Commonwealth Fund, are of special value in showing the "way the wind is blowing." *Government in Public Health*, by Dr Harry S. Mustard, is a thoughtful, temperate, review of the evolution of public-health work as a governmental function. It points out the rapidly changing philosophy and action of the federal government in the field of social security and the growing influence it is coming to exercise over state and local work through grants-in-aid. Communities or unions eligible for grants disbursed by the state departments of public health must conform in their health programs and personnel to certain standards and patterns set up by the United States Public Health Service. The other book, *Local Health Units for the Nation*, is a report of a subcommittee of the American Public Health Association by Dr Haven Emerson. This proposes to consolidate all local health organizations in the United States into 1197 jurisdictions, for example, Massachusetts would have 40 jurisdictions. Local boards of health would be abolished. The member of any board can examine the report and see just where his organization fits in, or fits out of, the plan.

It is not a new idea, nor one with which anyone would disagree, that certain basic health services should be provided for all communities, large or small through a governmental agency. Neither is it news that most rural communities and small towns and many larger towns and cities are not receiving proper health services. There are probably not over a score of the 351 communities in Massachusetts that have a first-class up-to-date program carried on by adequately trained persons. If we continue to believe that the people should have this service but do nothing to supply it locally, can we complain if outside force is used to consolidate or combine according to plans that are not entirely agreeable?

It is time that local boards of health woke up to their responsibilities and opportunities. They have both in full measure. Local boards are charged with carrying on an important function of government, and they are given extraordinary police powers and quasi-legal and quasi-judicial powers by state laws to fulfill this function. Yet many board members hardly know what their duties are, and they work under obsolete regulations and place the executive work in the hands of an untrained plumber or a busy practicing physician who can devote little time to his task. Most boards take little or no interest in health legislation that may vitally concern them, such as several bills pending this year in the Massachusetts legislature.

Are boards of health going to do anything about this, or are they going to permit themselves to be abolished and to have the state and federal governments step in and dictate how the goal of basic health activities for all should be provided? Local boards must forfeit some authority. Small communities must pool their interests to make a unit of sufficient size and resources to employ trained people. Subsidies are desirable but local communities should have something to say about any such plan.

Reform or improvement should start with the creation of better boards. Public-spirited citizens who take their duties as public servants seriously and who inquire what their duties are will see the need for improvement and find the way to solve the problem. There are now three ways in which communities may lawfully combine for health work in Massachusetts. Any district health officer knows the answers.

Physicians, as leaders in their communities and as logical candidates for boards of health, should give this serious thought. It is part and parcel of trends in medicine that need study and direction to arrive at the goal that is sought in medical care.

CURTIS M. HILLIARD
Professor of Biology and Public Health

Simmons College
Boston 15

FIRST BACTERIOLOGIC LABORATORY
IN MASSACHUSETTS

To the Editor In the January 10 issue of the *Journal*, an item was published regarding Dr. Francis P. Denny and his retirement as director of health of the town of Brookline. A statement was made that Dr. Denny established the first bacteriologic laboratory in Massachusetts outside Boston. I wish to set up an opposing claim.

I do not wish to detract in any manner from the accomplishments of my friend Dr. Denny. His pioneering in public health and the records in this field that he has earned for himself and Brookline have brought him an outstanding reputation in the Commonwealth and in the Nation, and the unstinted support given him by his community, not only moral but financial, speaks for his leadership in public health. I am sure, however, that Dr. Denny would be the first to disclaim priority to this historical distinction if it was shown to be otherwise.

The *Annual Report of the Worcester Board of Health* for the year 1894 makes the following statement: "To render more certain the diagnosis in cases of diphtheria, the Board of Health with the consent and approval of His Honor the Mayor, established in September last a bacteriologic department [This means September, 1894]. Since the establishment, the physicians of the city have generally availed themselves of its aid. Dr. Frederick H. Baker, a graduate of Harvard who has given a large amount of time to the study of this branch of his profession, is in charge." At the end of this section of the report it is stated: "We can make claim with pardonable pride for our city that it was the first to inaugurate a department of this character east of New York and one of the first to do so in the country. An establishment of this kind is fast becoming a branch of all well regulated health departments."

This service was a continuing service, as the annual report for 1895 states in regard to diphtheria, "There were 254 cases of this disease reported during the year with 70 deaths, a mortality of 27.55, the first inoculation in Worcester having been made January 5 by Dr. W. T. Clark, chairman of the Board, assisted by Dr. F. H. Baker, its bacteriologist." Dr. Baker continued to conduct the Board of Health Laboratory in the City of Worcester until shortly before his death in 1939.

On this evidence I claim for Dr. F. H. Baker and the City of Worcester the distinction of establishing the first laboratory in the Commonwealth of Massachusetts and in New England, which was second only to one in New York City for the country as a whole.

JAMES O. WAILS, M.D.
Commissioner of Public Health

Department of Public Health
Worcester, Massachusetts

We acknowledge the error and accept the correction, our information came from a presumably reliable source. To Worcester goes the distinction of having established the first bacteriologic laboratory in Massachusetts, unless some other municipality can successfully dispute the claim. — Ed

NOTICES

ANNOUNCEMENTS

Dr. Herbert Ahkowitz announces his return from military service and the reopening of his offices for the practice of medicine and surgery at 599 Broadway, Everett.

Dr. Walter S. Burrage announces his return to the practice of internal medicine and allergy at 330 Dartmouth Street, Boston.

Dr. Philip V. Harrington announces the opening of an office for the general practice of medicine at 28 Pleasant Street, Worcester.

Dr. Hermon Norton, having returned from military service, is opening his office for the general practice of medicine at 56 Pine Ridge Road, Waban.

adopted are given below. The detailed applications of these regulations to plasma distribution are further clarified where indicated.

1 Regulations for distribution and use of products derived from voluntary blood donations will be made by the Department of Public Health, following consultation with representatives of the Massachusetts Hospital Association, the Massachusetts Medical Society and an advisory committee of physicians experienced in the study and use of blood and blood derivatives.

2 Recommended uses for products will be defined by the department, after consultation with consultants. Use of products for conditions other than those recommended may be authorized by a regional consultant designated by the department.

The supply of plasma is not unlimited, and its use will therefore be restricted for the present to the emergency control of shock associated with trauma, acute hemorrhage, burns and other surgical or medical emergencies.

3 Distribution will be handled through the Division of Biologic Laboratories, Department of Public Health, which may establish depots at designated points in the Commonwealth.

Initial plasma shipments will be made from the Division of Biologic Laboratories, 375 South Street, Jamaica Plain 30, directly to licensed hospitals throughout the state. All hospitals are being notified that the plasma is available. Arrangements will be made at a subsequent date for distribution of plasma through a small number of regional distribution centers. To provide for major emergencies in the western part of the Commonwealth, an ample reserve of plasma is being transferred for storage in that area.

The initial shipments to general hospitals will be made on the basis of 1 unit of plasma for every four beds, the minimum shipment being 6 units. Initial allotments for chronic or special hospitals will be based on anticipated needs for two months, which should be indicated in requests. The recommended minimum stock for general hospitals is 1 unit for every ten beds or 6 units, whichever is larger. Replacement orders should be calculated to supply one month's needs. Replacements will not be shipped oftener than once a month except in emergencies. As nearly as possible, shipments will be made in case lots.

4 Products may be secured from the Division of Biologic Laboratories or from a depot by a hospital, a physician or an authorized representative of the above on signing a receipt. Certain designated products may also be distributed through boards of health.

Plasma may be issued from a hospital supply to a licensed physician or his representative on signing a receipt. Duplicates of such receipts are to be forwarded to the Division of Biologic Laboratories.

5 Products will be available to all physicians licensed to practice in Massachusetts, under the provisions outlined below.

6 No charge for the products may be made to the patient or at any step in their distribution. This provision does not preclude a reasonable charge for their administration to a patient.

7 Reports of the use of products are to be made out on the forms to be provided, and returned to the Division of Biologic Laboratories for study. Future development of distribution policies, clinical uses and investigation of new developments in blood products will be based on these reports.

The Army-Navy report form inside the package should be discarded. The Department of Public Health is furnishing a report form-postcard with each package. Physicians using plasma are urged to supplement these reports with letters regarding any subsequent reactions that may appear several months after the use of plasma. Any possible occurrence of homologous serum jaundice should be specifically reported, since it is of extreme importance to evaluate the significance of this complication of the use of plasma on a large scale.

*Made reportable December 1943

†Four-year average

COMMENT

Scarlet fever, diphtheria, mumps, measles and German measles were all reported at figures definitely below their seven-year medians, although record low figures were not approached.

Chicken pox was reported at the lowest figure in January of any corresponding month since 1923.

Pneumonia cases for the month were second only to the record low figures of January, 1945.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Boston, 3, Brockton, 1, Chelsea, 1, Lowell, 1, New Bedford, 2, Pembroke, 1, Taunton, 1, total, 10.

Dysentery, amebic, was reported from Camp Edwards, 1, Waltham Regional Hospital, 1, total, 2.

Dysentery, bacillary, was reported from Lowell, 2, Springfield, 1, Waltham Regional Hospital, 1, total, 4.

Encephalitis, infectious, was reported from Easton, 1, Milford, 1, total, 2.

Malaria was reported from Arlington, 1, Attleboro, 1, Boston, 19, Cambridge, 3, Camp Edwards, 3, Everett, 2, Fort Devens, 5, Gardner, 1, Haverhill, 1, Lawrence, 1, Natick, 1, New Bedford, 1, Newton, 2, Plymouth, 1, Quincy, 1, Salem, 2, Somerville, 2, Waltham Regional Hospital, 2, Worcester, 3, total, 52.

Meningitis, meningococcal, was reported from Arlington, 1, Barnstable, 1, Boston, 2, Brimfield, 1, Brookline, 1, Cambridge, 1, Dracut, 1, Fall River, 1, Framingham, 1, Groveland, 1, Lowell, 1, Lunenburg, 1, Malden, 1, Newton, 1, North Attleboro, 1, Quincy, 3, Springfield, 1, Watertown, 1, Wenham, 1, Weymouth, 1, Winchendon, 1, Worcester, 1, total, 25.

Meningitis, Pfeiffer-bacillus, was reported from Reading, 1, North Attleboro, 1, Worcester, 1, total, 3.

Meningitis, pneumococcal, was reported from Boston, 1, Northboro, 1, Quincy, 1, total, 3.

Meningitis, streptococcal, was reported from Wareham, 1, total, 1.

Meningitis, other forms, was reported from Boston, 4, Milton, 1, Taunton, 1, total, 6.

Meningitis, undetermined, was reported from Boston, 1, Camp Edwards, 1, Northampton, 1, Webster, 1, total, 4.

Salmonella infections were reported from Boston, 1, Cambridge, 1, Hingham, 1, Melrose, 2, total, 5.

Septic sore throat was reported from Boston, 5, Brockton, 1, Cambridge, 1, Fall River, 1, Medford, 1, North Adams, 1, total, 10.

Trachoma was reported from Chicopee, 1, total, 1.

Trichinosis was reported from Boston, 2, Wellesley, 1, total, 3.

Undulant fever was reported from Lenox, 1, total, 1.

THE REPAIR OF CRANIAL DEFECTS WITH SPECIAL REFERENCE TO THE USE OF CANCELLOUS BONE*

COMMANDER JOHN T. B. CARMODY (MC) U. S. N. R. †

THE treatment of defects of the cranial bones is a problem as old as cranial surgery. All types of material have been used, and the search for a completely satisfactory substance continues. The war has stimulated such endeavor, and there is no doubt that vast strides have been made. There has been a strong tendency toward the use of metal. Almost all metals have been tried in one form or another, each having its advocates and showing advantages over the others, but each possessing distinct disadvantages. Formerly, the most successful and most popular materials were silver and vitallium,¹ but other substances such as celluloid have had their followers. The repair of large cranial defects by silver plates has been successful for varying periods of time, but the majority of such plates have had to be replaced. Generally speaking, the use of silver is a thing of the past. In 1937, it was noted that vitallium caused only negligible tissue reaction and gave evidence of great promise,¹⁻⁴ but it was difficult to work with, and although still used this material has been superseded by tantalum.⁵⁻⁷

Burch, in 1938, first saw the surgical possibilities of tantalum,⁷ and Pudenz,⁸ in 1942, emphasized its future in neurosurgery in a paper on tissue tolerance of the metal in cats. It was also shown that a thin, filmy, translucent, gelatinous membrane enveloped the metal within forty-eight hours, thus tending to prevent fixation to the nervous tissue.⁹ On the other hand, some question has arisen through the experiments of Delarue,¹⁰ who, working with dogs, proved that tantalum could become attached to the cerebral cortex by firm adhesions and that the adjacent arachnoid and dura could become thickened. Recently, Robertson and Peacher¹¹ have found no such indication of tissue reaction in human beings, but there is evidence that such a complication may occur, as indicated in one of the cases reported in this paper.

Nevertheless, tantalum has been and continues to be the most satisfactory metal used in cranioplasty. It is light, nonmagnetic and chemically inert, is easily molded and does not require preliminary casting. It is soft enough so that drill holes can easily be placed at the time of operation, and no special instruments are necessary to handle it. In summary, tantalum offers inertness, mobility and strength—three factors not present in the metals previously used.

In the matter of basic requirements for an alloplastic material, it appears that the goal has been reached. Recently, several impressive series of cases receiving cranioplasty have appeared in the literature.^{9, 12, 13} The immediate results in many cases have been remarkable, but in spite of initial perfection, some evidence is accumulating that tantalum is not suitable in all cases. Heavily scarred areas that have remained intact for varying periods have gradually broken down, and once this process has begun, the basic inertness of the metal does not prevent it from being extruded like any foreign body. Again, the possibility of cortical fixation has not been completely disproved. Other disadvantages are gradually taking shape, such as the preclusion by a plate of any future x-ray studies. It is true that some of these disadvantages may arise from the technical difficulties of cranioplasty rather than from the metal itself. Also, it cannot be denied that the result of enthusiasm for cranioplasty has been that many cranial defects have been subjected to so-called plating that in former years and under different circumstances would have been let alone. Significantly, in this group are found cases with more complaints following repair than before it. Much has been written concerning the indication for cranioplasty, and almost any case of skull defect can be made to meet such requirements.^{6, 12, 13}

It seems more to the point to emphasize the contraindications. The clinical cases exhibiting them fall into two main categories—those with a simple "hole in the head" associated with no complaints, and those in which the complaints are consistent with functional involvement. There

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

A dinner meeting of the Middlesex South District Medical Society will be held at the Hotel Continental, Cambridge, on Wednesday, March 20, at 6 00 p m. Veterans of the district will be guests of the society. Others are welcome on payment of \$5 for dinner. The fees should be sent to Dr Fabyan Packard, 245 State Street, Boston. Dr E D Churchill will be the speaker, and Dr Harold Giddings will act as toastmaster.

SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, March 19, at twelve noon. Dr Moses H Lurie will speak on the subject "Deafness and a Few of the Emergencies in Ear, Nose and Throat." Dr H S Card will preside. Physicians are cordially invited to attend.

UNITED STATES PUBLIC HEALTH SERVICE

Examinations for appointments of medical officers in the Regular Corps of the United States Public Health Service will begin on April 4 at various convenient localities throughout the country. Examinations are for appointments to fill vacancies of assistant surgeon (first lieutenant) and senior assistant surgeon (captain).

Regular Corps appointments are permanent. They provide qualified doctors with opportunities for a career in one or more of a number of fields including research, general hospitals, special hospitals, foreign duty and public-health programs. Assignments are made according to careful consideration of the officers' demonstrated abilities and experiences. It is expected that doctors now leaving the armed services will find the openings of particular interest.

Entrance pay for assistant surgeon with dependents is \$3411 a year, and for senior assistant surgeon with dependents is \$3991 a year. Promotions are at regular intervals up to and including the grade of medical director, which corresponds to full colonel at \$7951 a year. Retirement pay at the age of sixty-four is \$4500 a year. Full medical care, including disability retirement at three-fourths pay, is provided. All expenses of official travel are paid by the Government. Thirty days' annual leave with pay is provided.

An applicant for the grade of assistant surgeon must be a citizen of the United States, must present a diploma of graduation from a recognized medical school, must have had or be in the process of completing the seventh year of college or professional training or experience since high-school graduation (two years premedical, four years of medicine and one year internship) and must have a physical examination at the place of oral examination by medical officers of the Service.

An applicant for the grade of senior assistant surgeon must meet the above requirements and must have had four additional years of postgraduate training or experience.

Examinations will be oral and written. The written examination will be held on May 14, 15 and 16 at places convenient to the candidate and the Service. National Board grades may be used for the assistant-surgeon examination. The oral examination will be held at 9 a m at the places and dates listed below.

NORTON MEDICAL AWARD

The book-publishing firm of W W Norton and Company announces that it is again inviting manuscripts for submission to be considered for the Norton Medical Award of \$3500 offered to encourage the writing of books on medicine and on the medical profession for the layman. The first such award was made to *The Doctor's Job*, by Dr Carl Binger, published last spring, which gave the doctor's point of view on his work. Announcement will be made shortly of the winning book for 1946. Closing date for submission of manuscripts this year is November 1. All particulars relating to requirements and terms may be had by addressing W W Norton and Company, Incorporated, 70 Fifth Avenue, New York 11, N Y.

doomed from the beginning. Consequently, a section of the plate underlying the main scar areas was removed. This allowed the soft-tissue edges to overhang the plate but in periphery which was adherent to the dura. Whether this picture was entirely the result of the infection could not be determined. The scalp was firmly attached to the plate in

site of tissue contact, further recession with attempted extrusion of the plate ensued, and as a result it was surgically removed. At the time it was noted that a multiloculated space, some areas being fully 2 cm. in depth, lay between a different manner than has been noted with nonperforated plates. The only form of treatment for the next several weeks was frequent irrigations with penicillin. The multiloculated

the advisability of cranioplasty is questionable. Opinion concerning its value when epilepsy is present is divided. At one extreme, Gardner¹²

reported has not been sufficient to warrant any definite conclusion, and although some suggestive improvement has occurred, it must be remembered that a cranial procedure of any type frequently effects a temporary change in the convulsive state.

The following 2 cases are summarized to illustrate some of the inadequacies of tantalum. They are presented not from the point of view of criticism of treatment but in an attempt to show that the use of bone in cranioplasty is not obsolete and that in certain cases this material should in fact be the one of choice.

CASE REPORTS

CASE 1 A 29-year-old veteran, was admitted to the hospital on February 16, 1945, with a diagnosis of meningitis. He complained of severe headache, a draining head wound and a stiff neck. He had been wounded in the head by a bomb fragment on September 23, 1943, and had developed successively a herniation of the right frontal cerebral hemisphere, right frontal osteomyelitis and epilepsy. Subsequently, several operations had been performed, including as a final procedure the insertion of a large tantalum plate. The patient was discharged from the service on January 8, 1945, at which time his general condition was excellent. The head wound had completely healed. During the next month, he experienced slight headaches and a feeling of tightness involving the right frontal region. These symptoms increased in severity and culminated in the breaking down of a portion of the heavily scarred scalp.

Physical examination on admission showed an acutely ill patient. The temperature was 101°F, and the pulse 110. The neck was slightly rigid, and a profuse thin, purulent discharge was issuing from the several presenting perforations in the exposed areas of the tantalum plate (Fig 1). The remainder of the examination was negative with the exception of a left-sided hyper-reflexia. Cultures were positive for a hemolytic staphylococcus.

The infection was readily controlled by chemotherapy, but further breakdown of the scar continued. X-ray examination showed a large and exceptionally well molded

FIGURE 2 Case 1

These films show the size of the tantalum plate. Many old fracture lines remain visible, indicating the extensiveness of the original injury.

believes that cranioplasty has been most beneficial. The time interval in the series of cases subsequently

and fitted tantalum plate (Fig 2). It was decided to save as much of the plate as possible. It seemed to be a foregone conclusion that a subsequent total cranioplasty would be

not to pierce through the scarred area to its external surface. This is an extremely easy thing to do, and is almost certain to result in tissue breakdown postoperatively. When the lower margin of the defect has been exposed and completely freed, all bleeding points — and there are often many, depending on the size and character of the scar — may be controlled more completely and easily with fibrin foam-packs than by any other combination of methods. Freshening up the bony edge around the defect should be avoided. The danger of diploic bleeding outweighs any suspected advantage that such a procedure may have.

With the bed prepared and all bleeding controlled, cancellous chips approximately 1 cm in diameter are placed in mosaic layers, entirely filling the defect. Chips of this size are readily obtained by biting them off from the graft with a rongeur. As a final step, when possible, the periosteum surrounding the exposed bone defect is incised and turned back over the borders partially enclosing the cancellous chips. Mowlem¹⁴ believes that this is not necessary and prefers to have the chips in direct contact with the denuded bone. The scalp flap is sutured and a light compression dressing is applied.

Postoperatively, formation of a hematoma occasionally occurs in spite of the utmost precautions before closure. Local application of heat accompanied by drainage at the most dependent region of the incision, results in quick resolution. When an extensive loss of underlying soft tissue has occurred, the original scar may break down. Irrigation with penicillin in a 1:1000 concentration is followed by rapid healing. This result is a decided contrast to the problem that arises when metal of any kind is used as the underlying material.

So far as the graft is concerned, firm union is present clinically in two or three weeks. Generally the x-ray picture in the early stage is that of intact and living bone without confirmatory evidence of union. The proper contour of the graft is readily maintained by the pressure of the overlying scalp against the easily molded mass of cancellous chips. Contour adaptability of the graft is the greatest single advantage of this method. The fact that Mowlem¹⁴ has had marked success in extensive facial-bone defects emphasizes the ease with which cancellous bone can be molded to fit the occasion.

That absorption of some elements of the graft may take place cannot be denied. This has occurred in some of this series of cases, but in none to the extent that the graft has lost its primary point of obliterating the defect. Actually, when absorption did take place only the chips that could be considered excessive were singled out, and in such a manner that the graft gradually progressed in contour and thickness to that of the normal adjacent bone.

The method of taking the graft is simple and

can be carried out in a few minutes. The crest of the ilium is exposed and the flat surface of the bone is laid bare. The outer cortical layer is split with a rotary bone saw and turned down. Thin strips of the medulla are sliced free and when a sufficient amount has been obtained the cortical layer is replaced and sutured into its former position. The hip wounds heal quickly, and there have been no complications or complaints other than soreness for the first two or three days.

DISCUSSION

It is not the purpose of this paper to condemn or undermine the use of tantalum in cranioplasty, but rather to advance the cause of cancellous-bone grafting in selected cases. An attempt has been made to show that cancellous bone may be the material of choice under certain circumstances and that its use should not be relegated to the past.

It is difficult to conceive of cancellous bone's fulfilling satisfactorily the obligation of repair either in exceptionally large defects or in those whose location precludes its use. With respect to

FIGURE 6 Case 3

This is a photograph of the patient taken two weeks postoperatively. The defect in the left orbital ridge and frontal sinus has been corrected.

the first type of case, the use of cancellous bone must be self-limiting. Sufficient bone to repair small and medium-sized defects is readily obtained from the ilium, as outlined above, whereas to take the amount of bone required for the larger defects would transform a minor procedure into one of major proportions. In defects of the orbital ridge and frontal sinuses, tantalum seems preferable, although Mowlem¹⁴ has used cancellous bone in this location with excellent results. Figures 5 and 6 depict a problem of this type.

cided on and was carried out. Prompt healing followed, and the last x-ray film showed that the graft was intact and united (Fig 3). At the present time the patient has no complaints referable to the head. Clinically the grafted area is sound. There is no pulsation, and the patient no longer feels as though, in his words, something were in his head that did not belong there.

CASE 2 A 20-year-old seaman was admitted to the hospital on May 8, 1945, with the complaints of headache and of swelling and tenderness in the left frontal region. He had had a frontal sinusitis on August 29, 1944, and had subsequently developed a left frontal brain abscess. The abscess was drained on November 5, and a small tantalum plate

preparation of the site of the bone defect is concerned. There are, however, several points that must be observed if rapid healing is to occur. In the first place, all scarred areas should be carefully avoided in making the incision, unless they are of such size and location that they can be resected at the time. In many cases the fractures have been extensively compounded, with severe loss of soft tissue, resulting in heavy scar formation and fixation to the underlying tissues, including the dura

FIGURE 5 Case 3

A shows a defect of the left orbital ridge and frontal sinus, with an unsatisfactory attempt at repair with bone, the bone graft was loose, sagged into the soft tissues of the orbit, with marked deformity, and caused severe pain due to tension on the supraorbital nerve. B is a film taken after removal of the graft and repair of the defect by a contour-fitting tantalum plate.

was inserted to prevent deformity. The patient showed prompt and immediate improvement and was discharged to full duty on April 26, 1945.

On admission he stated that he had been well except when he "caught cold." With the onset of each upper respiratory infection, he noted severe headache, swelling and tenderness about the site of the operation. These attacks at first subsided within a few days, but the last one was severe and resulted in admission to the sick list.

Physical examination showed an acutely ill young man. There was moderate swelling of the entire left frontal area. The tantalum plate could be palpated, and there was marked tenderness about its edges. There were no abnormal neurologic signs. The spinal fluid was within normal range with the exception of the pressure, which was equivalent to 250 mm of water. X-ray examination showed the presence of a small tantalum plate (Fig 4A). The lateral film suggested that the plate might be riding, and this was confirmed by the onset of pulsations with the regression of the swelling.

Conservative treatment was carried out until the acute phase of the infection had subsided. At operation on June 6, 1945, the plate was found to be riding and was removed. At the same time the defect was repaired with cancellous bone from the ilium. On the 6th postoperative day pulsations had ceased. Within 2 weeks the graft was firm, and the final film, taken 2 months later (Fig 4B) showed the bone graft to be intact and united firmly with the surrounding bone. The patient was followed for 2 months and remained free of complaints.

The operative technic in this procedure does not differ from that of any other method so far as the

or the cortex. When such areas, or even minor portions of them, have been included in the incision, some degree of incisional breakdown invariably follows. In many cases it is not feasible to attempt plastic correction of scarring as a preliminary step to defect repair, because of the extensive and complete adherence of the intracranial tissues to the overlying structure. Many patients have undergone several operative procedures, and the advisability of any further preliminary plastic repair before that of the defect has been accomplished is questionable. The treatment of these scars may be a major problem and is in itself a subject requiring separate attention.¹³ Finally, the wound should be completely healed before grafting is done. Occasionally, in exceptionally involved defects, as in Case 1, this is not possible. In this event, convalescence is lengthened and the danger of bone absorption is increased.

Following the making of the flap incision, the aponeurosis is dissected from the periosteum to the edge of the bone defect, and the scar, which may begin at the margin of the defect, is carefully dissected from the dura. It is most important

is that of all methods of repair cancellous-bone grafting is certainly the simplest and easiest. Plating by mortising the periphery of the bone defect may be an undertaking of considerable magnitude.^{14, 16} Fixation or wedging is simple when the exposure is easily achieved, but with involvement of the squamous portion of the temporal bone, even these methods become complicated. When impressions of the defect are made for casting, a two-stage operation is the rule. Simple fixation by tantalum screws reduces the operation to the level of grafting, but here again such a method is not always applicable.

Attention must be called to the fact that other materials than metals are being used in cranioplasty. Methyl acrylic, with which we have had no experience, is receiving support by its advocates,¹³ but its use also requires a longer procedure and a more elaborate setup. That it has any outstanding advantages over tantalum, with the exception of its being radiolucent, seems doubtful.

Recently, Mowlem¹⁴ has published a series of 75 cases of bone grafts in which cancellous chips were used exclusively. In most of the cases dealt with there were facial and long-bone defects, but there was 1 case of frontal-bone defect in which complete clinical healing with firm union occurred in ten days. This case has been followed for three years, during which period the graft has remained solid, with no evidence of absorption.

Mowlem attributes the marked success of cancellous bone for grafting to its highly vascular character. He believes further that fragmentation is a definite aid in the survival of these grafts on the theory that a greater proportion of the bone cells becomes accessible to early vascularization.

The chief objections in the past to the use of bone in defect repairs — namely, the extensiveness of the operation, often necessitating two stages, and the extreme difficulty of obtaining the proper contour effect — have been overcome by the use of cancellous bone. Furthermore, if the size of

the cranial defect is kept at a minimum at the time of the initial débridement, as has been frequently advocated, many unnecessarily large defects requiring the use of alloplastic materials can be avoided.^{17, 18} This in itself as a preventive measure would do much to reduce the number of cases requiring extensive cranioplastic measures.

CONCLUSIONS

Autogenous cancellous bone is the material of choice in small and medium-sized defects of the skull requiring cranioplasty.

The repair of cranial defects with tantalum is at present the procedure of choice when the defects are of such size that a sufficient amount of bone cannot be obtained without an extensive secondary procedure, or when the site of the defect renders tantalum the more suitable material.

On the other hand, in both simple and complicated medium-sized defects of the vault, cancellous-bone grafting is in every particular the best method. The last 7 cases receiving cranioplasty in this hos-

pital have been treated in this manner, and with one exception healing has been prompt. In the excepted case, there was a minor breakdown of tissue involving a portion of the original scar. Ir-

cidental subsidence of the defect caused by the complaints. In defect areas in which deformity had been marked, proper and satisfactory contour healing occurred, Figures 7 and 8 illustrate such a

FIGURE 7 Case 4

These photographs show a medium-sized defect, with contour deformity, in the right frontal bone

case Furthermore, some patients with plates have said that they are constantly aware of the presence of a foreign body—in their own words, “something that does not belong there.” It seems logical

to assume that no matter how inert a material may be it is still a foreign body, and if its presence can be avoided by the use of autogenous material, this should be employed. Another factor of importance

FIGURE 8 Case 4

rigations with penicillin were used, and rapid healing occurred. In all cases the grafts were clinically solid within two or three weeks. Defect pulsation disappeared in approximately one week, with a

to assume that no matter how inert a material may be it is still a foreign body, and if its presence can be avoided by the use of autogenous material, this should be employed. Another factor of importance

developed this symptom shortly after childbirth (Table 3)

A good deal of evidence, however, can be cited against the assumption that exertional incontinence

FIGURE 1

This patient had a reversed urethral curve. She had never been pregnant and had had no incontinence

invariably results from obstetric trauma. Typical exertional incontinence may occur without pregnancy or pelvic delivery, as shown by the case histories of the 5 nulliparas and 2 patients delivered by cesarean section. Trauma is therefore not a prerequisite for the development of urinary incon-

tion between trauma and the ensuing symptoms, which establishes their causal relation. This is not so with exertional incontinence. The extent of obstetric damage to the pelvic and perineal structures cannot be correlated with the degree of urinary leakage. Moreover, in the average case nine years are found to have elapsed before the patient first

FIGURE 3

This patient had prolapse of the uterus and a cystocele but no incontinence

noted loss of urine on coughing or sneezing. Many women do not become aware of poor urinary control until fifteen to twenty years after the birth of the

FIGURE 2

This patient had a large cystocele. There was a wide urethra and slight "funneling" of the internal sphincter, but no incontinence

tinence. The symptom complex, moreover, lacks the clinical attributes of a so-called "traumatic lesion." The sequelae of trauma are usually in direct proportion to the extent of injury. Thus,

the greater the injury, the more widespread are the effects. Furthermore, there is a definite time rela-

tion between trauma and the ensuing symptoms, which establishes their causal relation. This is not so with exertional incontinence. The extent of obstetric damage to the pelvic and perineal structures cannot be correlated with the degree of urinary leakage. Moreover, in the average case nine years are found to have elapsed before the patient first

noted loss of urine on coughing or sneezing. Many women do not become aware of poor urinary control until fifteen to twenty years after the birth of the last child, or indeed not until the menopause. This long time interval between cause and effect is not in keeping with experience in traumatic lesions elsewhere in the body and suggests strongly that the two are not causally related. A urethral lesion pathognomonic of exertional incontinence, moreover, has proved to be elusive. Evidence of its existence has been rather involved and indirect. Considerable interest has recently been evoked by Kennedy's¹⁻⁴ suggestion that fixation of a middle urethral sphincter by scar tissue causes exertional incontinence. No such specific lesion or deformity, however, was found on careful study among the 95 patients of this series. Furthermore, the sphincter to which Kennedy refers has never been demonstrated anatomically, and it is doubtful that one thus situated could be of any great

LACK OF A SPECIFIC URETHRAL LESION IN EXERTIONAL URINARY INCONTINENCE*

S RICHARD MUELLNER, M D †

BOSTON

IT IS generally believed that exertional urinary incontinence is due to trauma of childbirth. Although there is no agreement on the precise structure that has been injured, prevailing opinion ascribes this symptom to tears or fixations of the urethral sphincters or to attenuations of the bladder and urethral supports. The signs of obstetric trauma, however, are often not discernible on pelvic examination or at operation, and even when present they frequently cannot be correlated with the degree of urinary incontinence. Thus, marked urinary leakage may occur in patients with intact pelvic structures, whereas women who on exertion lose only a drop or two of urine may have a urethra and a bladder base that have obviously lost their normal attachments. Furthermore, a history of obstetric trauma may be absent, and it is well known that some women who have never borne children suffer from exertional incontinence. These facts suggest that the present ideas concerning the etiology of this condition require revision, and this need furnished the incentive for the present investigation.

A study of 140 women forms the basis of this report. Ninety-five patients had exertional incontinence, and 45 continent women who had had obstetric sequelae, such as cystocele, laceration of the perineum and prolapse of the uterus, were selected for control subjects. It will be seen from Table 1

the cystoscopic examination, particular attention was paid to the performance of the internal sphincter when closing and opening. In a few cases fluoroscopy of the bladder filled with a contrast medium (Diodrast) was done to study detrusor behavior. Infection of the urinary tract was ruled out by analysis and culture of a catheter specimen of urine.

Analysis of the data revealed no correlation between the number of deliveries, the difficulties of labor and the degree of incontinence, which was arbitrarily expressed on a basis of + to ++++. The percentile distribution of the various degrees of incontinence among the 95 patients studied is given in Table 2. The findings of the pelvic examina-

that the age, the obstetric experience and the bladder capacity of both groups were closely similar. The use of such a large control group was considered essential for the proper evaluation of the findings ordinarily associated with exertional incontinence.

The data obtained consisted of a detailed history, a complete physical examination, cystometry, cystourethroscopy, cystography and urethrography. At

tion could not be correlated with the severity of the incontinence. In many cases large cystoceles, uterine prolapse or extensive perineal tears were associated with only mild leakage of urine, whereas patients with marked incontinence had surprisingly good pelvic structures. The control group amply demonstrated that urinary continence need not be impaired by post-partum changes affecting the pelvis and perineum.

The cystometrograms, the cystograms and the cystoscopic findings were similar in both groups and revealed no specific criteria diagnostic of exertional incontinence. A properly functioning internal sphincter was demonstrable even in patients with marked incontinence.

The urethrograms revealed all sorts of urethral configurations without establishing an x-ray picture typical of exertional incontinence. The width and length of the urethra, its course in relation to the posterior surface of the symphysis pubis and its mobility had no demonstrable relation to urinary control (Figs 1-3).

DISCUSSION

The belief that exertional incontinence is caused by obstetric trauma is time-honored and has never been seriously questioned. This is understandable, because the majority of women who suffer from it have borne children and because some of them

PYOGENIC LIVER ABSCESS

Review of the Literature and Report of a Case Successfully Treated by Operation and Penicillin

LIEUTENANT COLONEL J. EDWARD FLYNN, M.C., A.U.S.*

PYOGENIC abscesses of the liver have caused death in at least half the patients afflicted with this disease, the mortality having ranged from 50 per cent, in Eliason's¹ series, to 95 per cent, reported by Brütt.² Since chemotherapy has proved to be of great value in many diseases caused by pyogenic organisms, it seems logical that one of these drugs might be useful in cases of pyogenic liver abscess, and a case so treated is reported.

ETIOLOGY

There are five ways in which pyogenic organisms invade the liver. First, they may travel through the portal vein from regions drained by it. Suppurative appendicitis, complicated by pylephlebitis, is one of the most frequent causes. In Ochsner's³ collected series of 575 cases, appendicitis was the source in 197 (24 per cent). In the 47 cases of Ochsner's own series, however, appendicitis was the source in 11 per cent. The latter is probably a more accurate figure, because in a series of 231 cases reported by Baerensprung,⁴ Rothenberg and Linder⁵ and Keefer⁶ appendicitis was the source in 15 per cent. Ulcerations of the stomach or bowel and diseases of the rectum, spleen and pancreas frequently cause hepatic abscess. In Ochsner's collected series, they constituted 10 per cent of all causes. Second, blood-borne infections may be transmitted through the hepatic artery. Osteomyelitis, furunculosis, ulcerative endocarditis, acute infections of the upper respiratory tract or pyemia from any source may be the cause. In Ochsner's collected series, 13 per cent were due to blood-borne infections. Third, there may be direct extension from a contiguous infection. A diseased gall bladder was the source in 14 per cent of Ochsner's collected series. Subphrenic abscess, empyema, nephritic or perinephritic abscesses and gastric and duodenal ulcers are less frequently the cause. Lastly, trauma may be the cause. This was so in 3 per cent of Ochsner's collected series. There may be a penetrating wound from a bullet or some other agent or a subcutaneous injury to the liver, producing traumatic changes in it and permitting the bacteria always present in this organ to grow.

Cases of pyogenic liver abscess in which the source cannot be determined form a relatively large group. In Ochsner's collected series, 17 per cent of the cases were of this type. In his own series of 47 cases, the incidence was 59 per cent. Such cases, Beaver⁷ believes, are due to lesions draining into the portal vein that are so small that they cannot be localized clinically, whereas Rothenberg and

Linder⁵ think that they are the result of hematogenous infections, secondary to small, inconspicuous distant foci. A case that falls into this group and in which pyogenic infection was due to nonhemolytic streptococci is presented below.

BACTERIOLOGY

The organisms that cause pyogenic abscesses of the liver are generally sensitive to the sulfonamides or to penicillin. The organisms most frequently found are colon bacilli, streptococci, staphylococci or a combination of two or all of these. In Ochsner's collected series, the responsible organisms were colon bacilli in 31 per cent of the cases, streptococci in 21 per cent, staphylococci in 17 per cent, and two or more of these three in 17 per cent. Organisms that are rarely found are *Clostridium perfringens*, *Pseudomonas pyocyaneus*, *Eberthella typhosa*, *Leptothrix*,⁸ *Streptothrix*,⁹ *Salmonella*,¹⁰ spirochetes¹¹ and gonococci.¹² Pus in pyogenic abscesses of the liver is frequently sterile. Rothenberg and Linder⁵ found sterile pus in 46 per cent of their series, whereas Elsberg¹³ reported it positive in 60 per cent of his series.

PATHOGENESIS AND PATHOLOGY

It has been mentioned that pyogenic hepatic abscesses may develop by extension of infection through the portal vein, through hepatic arteries as metastatic abscesses, by direct extension from a nearby organ or by trauma. Munro¹⁴ has stressed the lymphatic vessels, but most investigators believe that infection of the liver rarely if ever occurs by this route. The retroperitoneal route from the appendix to the liver has been mentioned by Korte,¹⁵ Loison¹⁶ and Walter-Sallis.¹⁷

The most frequent source is considered by most investigators to be suppurative appendicitis. The course of the infection is easy to follow as it proceeds from inflammation of the appendix to thrombophlebitis of the vessels in the appendix wall and thence to progressive phlebitis of the appendiceal, ileocecal, superior mesenteric and portal veins. A septic embolus can, however, be detached from the thrombus in the appendiceal region. Most hepatic abscesses that follow appendicitis are multiple and involve the right lobe of the liver. The existence of two currents of blood in the portal vein, one from the superior mesenteric vein, which leads to the right lobe of the liver, and one from the inferior mesenteric and splenic veins, which lead to the left lobe, has been demonstrated by Sérégé,¹⁸ Glénard,¹⁹ Bartlett, Corper and Long²⁰ and Copher and Dick.²¹

From the pathological standpoint, the first con-

importance to urinary continence. More than two thirds of the female urethra can be safely excised — as it usually is for carcinoma of the urethra — without causing loss of urinary control,^{5, 6} showing that the normal mechanism responsible for continence does not reside in the distal two thirds of the urethra.

The only significant urethral sphincter, according to recent investigations, consists of the fibers of the detrusor at the bladder outlet or neck.⁷⁻¹⁰ This sphincter is an integral part of the detrusor, and its behavior is entirely dependent on it, as was shown by the studies of Denny-Brown and Robertson^{11, 12}. These authors have clearly demonstrated that no independent relaxation of the internal vesical sphincter can occur without corresponding contraction of the detrusor. The bladder neck therefore cannot open even partially unless the detrusor contracts simultaneously. For the escape of urine, to be interrupted, detrusor contractions must be inhibited.

The function of the detrusor in exertional incontinence was investigated in a series of 7 patients. The bladder was filled with Diodrast, and its behavior was observed under the fluoroscope. When micturition was initiated, contraction of the bladder dome was first seen. This was followed by straightening of the lateral walls and centripetal contraction of the entire bladder muscle. When requested to inhibit the urinary stream, control subjects were promptly able to relax the detrusor. Patients with exertional incontinence, on the other hand, invariably accomplished this only with difficulty. The detrusor muscle continued to contract for a variable time after the initial voluntary effort to stop urination, this interval being commensurate with the degree of incontinence. Patients with marked incontinence either inhibited the bladder contractions late during urination or proceeded to complete the micturition.

These observations, although based on the study of a small series of cases, nevertheless emphasize the importance of proper detrusor function in normal micturition and in the presence of urinary incontinence. They suggest that exertional incontinence is due to an acquired irritability of the detrusor that permits minor stimuli, such as are set off by coughing or sneezing, to produce detrusor contractions, with corresponding relaxation of the internal sphincter and urinary leakage. If this assumption is correct, the source of the trouble in exertional incontinence is not in the urethra, its sphincters or supports but in the bladder muscle itself and its internal sphincter. The normal mechanism, which keeps the detrusor relaxed until micturition is initiated or which relaxes it at will when the urinary stream is to be inhibited, is disturbed. The cause of such an acquired detrusor dysfunction, however, must at present be regarded as unknown. In pre-

vious reports it was shown that the bladder muscle can be strikingly affected by hormones.^{13, 14} The hormonal changes associated with pregnancy and the puerperium profoundly alter bladder capacity and tonus. Hormonal changes occur also at the menopause, when many women first develop exertional incontinence. The precise relation between female hormones and this type of urinary leakage, however, is yet to be established.

The concept of exertional incontinence as a functional bladder disturbance undermines the basis on which the present methods of surgical treatment rest. The various plication operations and the procedures involving the use of fascial slings around the urethra do not attack the problem at its root. By their fixation of the bladder neck they do, however, make it difficult for the internal sphincter to open easily in response to detrusor contractions. It is probably for this reason that overfixation of the bladder neck has often led to inability to void, whereas insufficient fixation has produced only fleeting relief from incontinence.

SUMMARY

No specific urethral lesion was found in a study of 95 patients with exertional incontinence, as compared with 45 control subjects.

The belief that obstetric trauma causes exertional incontinence is critically reviewed, and the conclusion is reached that it is not an etiologic factor.

Evidence is presented that exertional incontinence is due to an acquired dysfunction of the detrusor rather than to anatomic defects.

the anteroposterior view and of the posterior costophrenic angle in the lateral view. Miles⁴⁴ showed that a gastrointestinal series in the presence of an abscess in the left lobe of the liver presents a deformity in which the lesser curvature of the stomach assumes a crescentic shape and the cardia and duodenal cap are displaced.

DIFFERENTIAL DIAGNOSIS

It is often possible to differentiate multiple and single abscesses of the liver. The former have an acute, sudden onset and are usually secondary to pyelephlebitis and suppurative appendicitis, whereas single pyogenic abscesses generally have an insidious onset and in many cases it is impossible to determine the source. Fever, chills and leukocytosis are more prominent with multiple than with single abscesses. Amebic abscesses of the liver usually have an insidious onset. The temperature is only slightly increased, chills rarely occur, and *Endamoeba histolytica* may be found in the stools.

Intrahepatic — toxic or infectious — jaundice is accompanied by damage to the parenchymal liver tissue. The van den Bergh reaction is generally direct.⁴⁵ There may be no pain and little or no fever, and the onset is usually insidious.

Acute cholecystitis and empyema of the gall bladder must frequently be considered. In cases in which there are definite pathologic changes in the right upper quadrant of the abdomen, a conscientious perusal of the past history may be a great aid in establishing a diagnosis of acute cholecystitis. If there have been repeated attacks after the ingestion of fatty or fried foods or repeated attacks of colic of the type associated with gallstones, it is reasonable to assume that the gall bladder is the seat of the trouble. Nausea and vomiting are frequent. Definite localized tenderness and rigidity of the right rectus muscle in the upper quadrant of the abdomen can be demonstrated.

Exploratory aspiration of the liver for detection of pus in pyogenic hepatic abscess is a dangerous procedure and should be condemned because of the danger of contaminating the pleura or peritoneum. This condition can be readily diagnosed by other methods.

PROGNOSIS

In the past, the prognosis with hepatic abscess has been extremely poor. Dieulafoy⁴⁶ in 1898 held that hepatic abscess following appendicitis was invariably fatal. Thompson⁴⁷ and Gerster⁴⁸ a few years later wrote of the seriousness of the condition. In 1914, Petrén⁴⁸ reported a mortality of 93 per cent. Later, Brütt² recorded one of 95 per cent, and in 1932 Otschkin⁴⁹ gave one of 80 per cent. Ochsner³ clearly demonstrated that the mortality is much greater with multiple abscesses (95 per cent) than with single ones (37 per cent).

Obviously the prognosis in cases of pyogenic

hepatic abscess has been extremely grave, and it is of interest that the mortality rate has changed little during the last fifty years. With chemotherapy, however, it should be greatly reduced.

TREATMENT

As a prophylactic measure in cases of appendicitis with a history of preoperative chills, the appendiceal ileocolic, superior mesenteric and portal veins should be examined during operation, as suggested by Melchior⁵⁰ and Thalheimer.⁵⁰ This may reveal a thrombosis, prompt treatment of which may prevent the development of hepatic pyogenic abscess. It seems likely that chemotherapy will also prove to have great prophylactic value.

The treatment of pyelephlebitis is surgical. Melchior⁵¹ reported 13 cases in which ligation of the ileocolic vein was performed. Eight of these patients had ligation at the time of appendectomy or drainage, and none died. In the other 5 cases ligation was performed after the primary operation, and 1 patient died. In 1935 Stewart-Wallace⁵² reported 15 cases in which primary ligation was performed. Two patients died from peritonitis. He also reported 6 cases in which the superior mesenteric vein was ligated. 4 patients recovered. Stewart-Wallace concluded that it is possible to ligate the superior mesenteric vein at or below the levels of the transverse mesocolon and the third part of the duodenum without the development of bowel necrosis.

Incision and drainage is the proper treatment of solitary pyogenic hepatic abscess. Ochsner³ stresses the importance of using the type of drainage that avoids the possibility of contamination of the pleura or peritoneum.

An extraperitoneal anterior or posterior approach may be made, depending on the location of the abscess. With an abscess on the anterior or antero-inferior surface of the liver, a procedure similar to that described by Clairmont and Meyer⁵³ for drainage of subphrenic abscesses should be used. A skin incision is made anteriorly just beneath and parallel to the costal margin. The external and internal oblique muscles and transversalis fascia are cut. The parietal peritoneum is carefully dissected from the inferior surface of the diaphragm. If the abscess is reached it is drained extraperitoneally at this stage. If it is not reached extraperitoneally, the visceral and parietal surfaces of the peritoneum are made to adhere by packing the area with gauze impregnated with some irritative substance, and drainage is later performed through this area.

If there is no sign of localization of the abscess in the anterior abdominal region, the retroperitoneal approach described by Ochsner³,⁵⁴ is used. A skin incision is made directly over the twelfth rib, which is resected subperiosteally. A transverse incision is made through the resected bed of the

sideration is the pylephlebitis. The infection in most cases invades the vein from without, the phlebitis being preceded by inflammation in the wall of the appendix. The inflammatory process may extend along the course of the vein, so that phlebitis has every facility for extension. The wall of the vein is infiltrated with leukocytes. Thrombosis rapidly occurs. The clot softens and mingles with the pus from the vessel wall. The inflammatory process may weaken the wall, with subsequent dilation of the vein, which may perforate, permitting the escape of blood and pus into the hepatic tissue. In other cases the inflammation is carried to the wall of the vein, with the early formation of a septic thrombus. Septic emboli may be carried through the portal system and produce hepatic abscesses.

Grossly the liver is enlarged. The abscesses are usually multiple, they vary in diameter from 0.5 mm to 1.0 cm and are generally confined to some particular section of the liver, the right lobe being involved oftener than the left. The multiple abscesses give the liver a mottled appearance. Small abscesses may coalesce, forming larger ones, and large solitary abscesses may become chronic. Beaver⁷ has described granulomatous abscesses of the liver.

The lung or pleural cavity may be involved by a spread of infection through the diaphragm, or rarely by a septic embolus. Usually a solitary abscess in the right lobe of the liver is the cause of pleuropulmonary complications. In Ochsner's³ collected series, pneumonia was a complication in 11 per cent of the cases, lung abscesses were present in 9 per cent, and empyema was found in 4 per cent.

Peritonitis may occur as the result of rupture of the abscess into the peritoneal cavity or following transperitoneal drainage of the abscess. In Keefe's⁶ series, peritonitis complicated liver abscess in 8 per cent of the cases. Subphrenic abscess was found as a complication in 6 per cent.

If the hepatic abscesses are due to pyemia, abscesses may also be found in the lungs, kidneys, spleen and brain.

Unusual complications have been reported by some investigators. Rupture of a hepatic abscess into the pericardium has been reported by Keefer⁶ and Azar,²² into the abdominal wall, by Huard et al.,²³ into the vena cava, by McKnight²⁴ and into the thoracic duct by Nieweg.²⁵ The occurrence of a pulmonary infarct has been cited by Keefer.⁶

SYMPTOMS AND SIGNS

The usual systemic symptoms are fever, chills, pain and profuse sweating. Less often malaise, anorexia, loss of weight, weakness, nausea and vomiting occur. Fever may be continuous, intermittent or remittent. With acute suppurative appendicitis complicated by pylephlebitis and multiple abscesses of the liver, fever is of the so-

called "picket-fence" type and is generally accompanied by daily chills. Rothenberg and Linder⁵ observed that daily chills occurred frequently with multiple hepatic abscesses but were rare with a single abscess. As far back as 1897 Bryant²⁶ called attention to the significance of chills and fever during the course of appendicitis. Brown,²⁷ Gerster,²⁸ Babler,²⁹ Thalheimer,³⁰ Eliason,¹ Ochsner et al.³¹ and others have emphasized this point.

Pain is felt in the right upper quadrant of the abdomen and is usually constant. In Ochsner's collected series, pain was present in 91 per cent of the cases. Dixon and Murphy³² observed radiation of pain from the right hypochondrium to the right shoulder, probably owing to irritation of the phrenic nerve. Rothenberg and Linder⁵ believe that irritation of the phrenic nerve seldom occurs, but state that over one third of patients complain of pain in the right lower chest on inspiration, indicating a diaphragmatic pleurisy. Intercostal pain may occur, as described by Rothenberg and Linder, Eliason¹ and Alessandri.³³ Weakness, anorexia and loss of weight are frequent. Nausea and vomiting seldom occur and were present in less than one third of Ochsner's collected cases.

Tenderness over the liver area and hepatic enlargement are frequent local signs. Rothenberg and Linder⁵ found tenderness in all their cases and hepatic enlargement in 92 per cent.

Jaundice occurs infrequently and is usually a late serious sign. Jaundice occurred in 8 per cent of Rothenberg and Linder's cases and in 25 per cent of Ochsner's collected series. Ascites is rare.

LABORATORY DATA

Leukocytosis, with an increase in polymorphonuclear leukocytes, is almost invariably present. The contrast between the moderate leukocytosis accompanying amebic abscess and the greater leukocytosis of pyogenic hepatic abscess has been mentioned by Rogers,³⁴ Manson-Bahr and Willoughby³⁵ and Ochsner and DeBakey.³⁶ The leukocytosis in acute cases is about twice as high as that in chronic cases.

Urinalysis is usually negative, but with jaundice bile is found in the urine, and with marked toxemia there is albuminuria.

Ochsner³ believes that roentgenography is one of the most significant and reliable aids in the diagnosis of liver abscess. The elevation and immobility of the diaphragm, usually on the right, as seen by x-ray are of high diagnostic value according to Pancoast,³⁷ Dickinson,³⁸ Love³⁹ and Oschner.³ Granger⁴⁰ and Ochsner and DeBakey^{36, 41-43} have observed that in subphrenic abscess complicating liver abscess there is obliteration of the cardiophrenic angle in the anteroposterior view and of the anterior costophrenic angle in the lateral view, whereas in subphrenic abscess due to other causes there is obliteration of the costophrenic angle in

A case of multiple pyogenic hepatic abscesses is presented. This case may be the forerunner of many others in which the patients survive when treated properly with penicillin or sulfadiazine. Etiologically, this patient belonged to the so-called "idiopathic group," in which the source of the infection cannot be determined. The organism was a nonhemolytic streptococcus sensitive to penicillin. Recovery followed penicillin therapy of three weeks' duration.

twelfth rib and the serratus posterior inferior muscle at the level of the spinous process of the first lumbar vertebra. The pleura at the costophrenic angle never extends below the spinous process of the first lumbar vertebra. The retroperitoneal space is entered between the upper pole of the kidney and the inferior surface of the liver. The parietal peritoneum is dissected from the undersurface of the diaphragm and the liver abscess is drained extraperitoneally. The importance of an extraperitoneal approach is stressed by Ochsner,³ who cites a mortality of 33 per cent with an extraperitoneal approach, one of 67 per cent with a transpleural approach and one of 73 per cent with a transperitoneal approach.

Chemotherapy should play a significant role in the decrease in mortality with multiple pyogenic abscesses of the liver. If operation is performed it is important to culture the organisms and test their sensitivity to penicillin and to sulfadiazine.

* * *

A case of multiple pyogenic abscesses of the liver, due to nonhemolytic streptococci, with no demonstrable focus, is presented below. The organism was sensitive to penicillin. The patient made a complete recovery. No similar case can be found in the literature.

CASE REPORT

The patient was a 23-year-old American soldier, born in Italy. The first symptom was a dull pain in the right upper quadrant of the abdomen, which lasted for 30 minutes. The pain recurred in 2 days, and the patient was admitted to a station hospital. The pain was intermittent and dull and persisted for 3 days. On the 3rd day after the onset of symptoms, the patient became jaundiced. On the 8th day, chills and a temperature of 101°F developed, persisting for 3 days. On the 14th day, a temperature of 101°F and chills recurred and lasted for 2 days. On the 21st day, pain recurred in the right upper quadrant of the abdomen. The patient vomited twice and had chills and a temperature of 102°F. Pain persisted for 1 day. On the 26th day, pain, fever, chills and vomiting recurred and lasted for 1 day. Jaundice and clay-colored stools persisted for 3 weeks. A diagnosis of catarrhal jaundice was made. After 5 weeks the patient was transferred to a convalescent hospital.

The patient was symptom-free for 3 days while in the convalescent hospital. On the 41st day after the onset of symptoms, the fifth attack of pain occurred. Pain was felt in the right and left upper quadrants of the abdomen and radiated to the right shoulder. The patient vomited once and jaundice recurred for the second time. There were chills and a temperature of 103°F. On physical examination there was tenderness and spasm over the right upper quadrant of the abdomen. The white-cell count was 16,500. Pain and jaundice persisted for 1 week.

The patient was symptom-free for the next 10 days. Pain in the right upper quadrant recurred for the sixth time, and jaundice for the third time. The liver edge was palpated 2 fingerbreadths below the costal margin. There were tenderness and spasm in the right upper quadrant. A diagnosis of probable empyema of the gall bladder was made, and the patient was prepared for surgery.

Operation was performed under spinal anesthesia, and the abdomen was opened. The liver was enlarged, with many white areas varying from 1 mm to 5 cm in diameter. A large, fluctuant mass measuring 5 cm in diameter was seen. Pus was aspirated from the abscess and a biopsy of the liver edge was performed. The gall bladder was distended, and grayish fluid was aspirated from it. The common duct was not dilated. A cholecystostomy was performed, and a

cigarette drain was inserted in the right subhepatic region. The wound was closed in layers except for the drain. A culture of pus aspirated from the abscess at operation showed microaerophilic nonhemolytic streptococci. The organisms were sensitive to penicillin, the zone of inhibition being 18 mm in diameter.

The pathological report was as follows. The gross specimen consists of a section of the liver measuring 5 by 3 by 2 cm. A gray area of pin-point size is seen in the yellow gray surface. Lobulation cannot be made out.

Microscopical examination shows that about half the normal architecture has been destroyed by an acute inflammatory process in and about the bile ducts, with necrosis of the adjacent liver cords and abscess formation. In addition to infiltration by polymorphonuclear leukocytes, there are a considerable number of eosinophils in the inflammatory reaction. There is hyperplasia of duct epithelium and early fibroplastic replacement of destroyed parenchyma. Diagnosis: acute cholangitis, with abscess formation.

Urinalysis was negative except during the periods when the patient was having pain and jaundice, when bile and albumin were found. On the day of operation the urine was amber, the specific gravity was 1.010, and there was a +++ test for albumin. There was an acid reaction, and no sugar and the test for bile was strongly positive.

The white-cell count during the acute attacks ranged from 10,500 to 21,000, with 79 per cent segmented neutrophils, 12 per cent lymphocytes, 6 per cent stab forms, 2 per cent monocytes and 1 per cent eosinophils. The red-cell count during the acute attacks ran about 3,100,000, with a hemoglobin of 78 per cent. Multiple smears showed no malarial parasites.

The icteric index during the phases of jaundice ranged from 11 to 43. The prothrombin time on the day before operation was 4 minutes for the patient and 3 minutes for the control. Three weeks postoperatively it was 16 and 6½ minutes, respectively, and 5 weeks postoperatively it was 5.5 and 4 minutes, respectively.

Three weeks preoperatively, the van den Bergh reaction was indirect, with 0.3 mg. per 100 cc. Three weeks postoperatively, it was again indirect, with 2.4 mg. and 4 weeks postoperatively it was indirect, with 2.1 mg.

Serologic tests for syphilis, tularemia, undulant fever and typhoid fever were negative. Dark-field examination of the blood was negative. Multiple stool examinations were negative for bile, occult blood, parasites and ova.

Blood cultures taken 4 weeks and 1 week preoperatively showed no growth. Culture of bile from the cholecystostomy showed nonhemolytic streptococci, nonhemolytic staphylococci and gram-negative rods not of the enteric group. Many x-ray films of the chest and abdomen showed no abnormality.

An electrocardiogram taken 3 weeks preoperatively showed sinus tachycardia. Low amplitude and low T waves were observed, findings similar to those in coronary disease, early pericarditis and systemic infection of long standing.

The patient was given 20,000 units of penicillin every 3 hours for 3 weeks postoperatively. Intravenous therapy was given for 4 days, and oral feeding was then begun. Five days postoperatively the temperature became normal and remained so. The cholecystostomy tube fell out on the 5th day. The wound was entirely healed 16 days after operation, when the patient was permitted out of bed. He was discharged 6 weeks after operation. A check-up examination 5 months after operation was negative. The patient will be followed indefinitely, especially for signs of biliary cirrhosis.

One and a half years postoperatively, the patient reported that he was well.

SUMMARY

Pyogenic hepatic abscess has caused a mortality of 50 to 95 per cent in patients afflicted with this disease.

Since the infection is usually caused by an organism that is sensitive to the sulfonamides or penicillin, chemotherapy should cause a great decrease in the mortality, but early diagnosis and proper operative procedures are also important.

730 consecutive cases of acute appendicitis admitted to St Thomas's Hospital in London. They believe that all patients save those presenting a palpable mass should be operated on soon after admission. They recognize that children are exceptions to this rule, and advise modification of this dictum in pregnancy and in the aged. Eight of the 21 fatalities in their series were in patients over sixty years of age.

The above two reports are in accord with the findings of Rogers and Faxon,⁸ who studied the appendicitis data from the Massachusetts General Hospital. The rationale of not spreading a localized inflammatory mass by immediate appendectomy is obvious. The abscess can be drained if it develops, and the appendix can be safely removed a few weeks later. Better preoperative and postoperative management has reduced the morbidity and mortality in cases with spreading peritonitis. There still remains an occasional case of this sort in which the patient is too ill for immediate surgery.

Sewell⁹ reports on two groups of patients from the same community and attributes a marked improvement in results largely to the use of sulfonamides. He reports the loss of 1 patient in the last consecutive 300 cases of appendicitis treated. Of these, the appendix was gangrenous in 31 cases and was perforated at the time of operation in 33. Sewell believes that the elimination of drains and the change from catgut to fine silk have also contributed to the reduction of intestinal obstruction and wound infection.

Obstructive appendicitis is discussed by Bowen.¹⁰ He reviews Wilkie's¹¹ original concept of this type of appendicitis. It appears that about 14 per cent of all Bowen's cases of acute appendicitis were of the obstructive type. In 38 cases studied for the cause of this condition, a stercorolith was present in 21, kinks and bands in 4, and stenosis in 1, whereas in 12 cases the only etiologic factor seemed to be spasm. Inasmuch as fever develops late and leukocytosis is always present early, there is little excuse for not recognizing this entity before perforation occurs. Since this type of appendicitis accounts for most of the cases of associated peritonitis due to early rupture of the appendix, and therefore for most of the deaths in appendicitis, it is all the more important to have this possibility in mind when acute abdominal symptoms occur.

Knox¹² reviews the literature on primary lymphosarcoma of the appendix and cites another case, making a total of 24 cases so far reported. Of twelve and a half thousand appendectomies performed at St. Luke's Hospital, New York City, since 1910, this was the only case in which such a diagnosis was made.

BILIARY SYSTEM

From the literature since 1900 Dixon and Lichtman¹³ have collected 50 cases of congenital absence

of the gall bladder, and have added 10 cases from the records of the Mayo Clinic. Fifty-eight per cent of these 60 patients had symptoms of cholelithiasis, 48 per cent had jaundice, and 27 per cent had gallstones in the ducts. Of the patients beyond the age of forty-five, 73 per cent had developed symptoms referable to the biliary tract.

Two case reports of papilloma of the gall bladder are presented by Greenwald.¹⁴ Such patients have the symptoms found in the more frequent pathologic states of the biliary system. The diagnosis is made by roentgen-ray examination after administration of the usual dye for cholecystograms. Palpation of the gall bladder does not reveal the lesion, because the papillomas are soft. Cholecystectomy is recommended. The possibility of malignant degeneration is discussed.

Smith¹⁵ has reported the experience of the Presbyterian Hospital, New York City, with acute cholecystitis for a ten-year period ending in 1941. He concludes that operation should be undertaken as soon as the patient is properly prepared and optimum operating-room facilities are available. The operative mortality increased with the duration of the acute process. Two hundred and twenty-three patients had cholecystectomy, with 8 deaths, a mortality of 4 per cent. Of 103 who had cholecystostomy, 12 died. There was an overall mortality of 7 per cent, which corresponds closely to the mortality of a similar group of patients at the Massachusetts General Hospital.¹⁶

An excellent discussion on the pitfalls in cholecystectomy has been presented by Simon.¹⁷ Schematic drawings and some photographs taken at operation illustrate the numerous anomalies that may be found in the ducts and blood vessels of the gall-bladder region. The author believes that these variations account for many of the catastrophes occurring during cholecystectomy. He thinks that the surgeon obtains a better opportunity for recognizing the anomalous as well as the normal structures by making the dissection from the fundus of the gall bladder toward the ducts.

Colp¹⁸ has reported the results of repair in 5 cases of traumatic stricture of the hepatic ducts. He used a fenestrated tube placed well up in the right hepatic duct and led into the duodenum. In 1 patient, the tube was brought out through the stomach wall and failed because it had to be removed on the eleventh day after a gastric fistula had developed. One patient was well for four and a half years, 1 for one and a half years, and 1 for two months. The remaining 2 patients have had recurrent chills and fever.

Peterson and Cole¹⁹ treated 3 patients for biliary obstruction due to sclerosing pancreatitis. All had different types of operative procedures to restore the bile flow to the gastrointestinal tract. These authors prefer the Roux type of operation, and have tried to make valve-like infoldings in the segment

MEDICAL PROGRESS

ABDOMINAL SURGERY

ARTHUR W. ALLEN, M.D.*

BOSTON

MANY contributions relating to surgical lesions of the abdomen have been reviewed during the past year. It is impossible to refer to all of them in this report, but a large proportion of the most significant are mentioned, and comments are made according to their relation to experience at the Massachusetts General Hospital.

ANESTHESIA

Lemmon and Hager¹ have reported on continuous spinal anesthesia in 2000 cases. They had no deaths and few complications from this method. Of these patients, 3.1 per cent had post-anesthesia headache, 3.3 per cent had urinary retention, and 2.3 per cent had pulmonary complications. Four and one tenth per cent of the patients died from causes unrelated to the anesthesia in an average of about six days. The surgical procedures were mainly abdominal and pelvic but included forty-eight thoracic operations.

This experience is in accord with that of Arrowood and Foldes,² who have modified Lemmon's method by a continuous intrathecal novocain drip. The patient is often kept asleep by small doses of Pentothal Sodium given intravenously as an adjunct to the spinal novocain. In this modification the relaxation of the abdominal muscles is continuous and completely satisfactory to the surgeon.

HERNIA

Singleton and Stehouwer³ report their experience with the fascia-patch method of hernia repair in 129 cases, supplementing a preliminary report on 44 patients made in 1916. They remove a semilunar-shaped piece of fascia lata and suture it to the structures bordering the inguinal canal. They have had recurrences in 3 per cent of indirect, 11 per cent of direct and 18 per cent of ventral and incisional hernias — an average rate of 11 per cent. They point out that 62 per cent of their cases had had previous repairs and that most of these were described as difficult.

Mair⁴ makes a preliminary report on the use of a whole-thickness skin transplant in the repair of hernia. The region is prepared with soap and water for three successive days before operation. The incision over the hernia is elliptical, so that a piece of skin measuring 2.5 by 5.0 cm. can be obtained and

placed in normal salt solution. The cord is elevated the sac is attended to in the usual manner, and the floor of the canal is narrowed by sutures. The graft is then freed of fat, cut off square at both ends and sutured under the cord to the rectus fascia, Poupart's ligament and the conjoined tendon. The outer end of the graft is split and sutured around the cord to make a new internal ring. Cultures from the graft have occasionally yielded *Staphylococcus albus*. In spite of this, there were only 2 cases of wound infection in 88 cases, and apparently neither of these caused sloughing of the graft. Mair's experimental work on rabbits and the re-exploration of the region of the graft three months later for some reason in one of his patients enables him to state that skin under these circumstances changes its character to a white fibrous structure. His patients were allowed up on the twentieth postoperative day.

Skinner and Duncan⁵ report on one hundred and twenty-six recurrent hernias repaired by them, with four failures, which were due to incorrect selection of procedure, infection, cough and poor tissues. They encountered five types of recurrence, namely, at the internal ring, near the pubis, at the midportion of the canal, as a femoral hernia overlooked at the first operation and as a general bulge below the repair.

Many reports substantiate our belief that when hernias are recurrent or large or the tissues are poor, the fascial-strip method of Gallie and LeMeasurer is the simplest procedure and offers the best opportunity for cure.

APPENDICITIS

Ochsner and Johnston⁶ have made a comparative study of the records on patients admitted to the Charity Hospital in New Orleans with appendiceal peritonitis in the years 1933 and 1943. The percentage of ruptured appendices was reduced, but the percentage of cases having received preadmission catharsis remained unchanged. There was a lower mortality and a lower morbidity rate in the more recent group of cases. These authors give credit to chemotherapy, the use of blood and plasma, more logical fluid replacement and delayed wound closure for their better results. They stress the use of delayed operation only in the presence of a palpable mass.

This is in accord with the viewpoint of McPherson and Kinmonth,⁷ who have analyzed the records of

*Lecturer in surgery, Harvard Medical School; chief, East Surgical Service, Massachusetts General Hospital.

730 consecutive cases of acute appendicitis admitted to St Thomas's Hospital in London. They believe that all patients save those presenting a palpable mass should be operated on soon after admission. They recognize that children are exceptions to this rule, and advise modification of this dictum in pregnancy and in the aged. Peterson and Cole¹⁹ treated 3 patients for biliary obstruction due to sclerosing pancreatitis. All had different types of operative procedures to restore the bile flow to the gastrointestinal tract. These authors prefer the Roux type of operation, and have tried to make valvelike infoldings in the segment

of bowel leading away from the liver in an effort to prevent regurgitation of gastrointestinal contents into the hepatic system

I²⁰ have described in detail a method of re-establishing continuity between the hepatic ducts and the intestine, based on the Roux principle. Fourteen patients have been operated on by this method so far. In those whose ducts are large and the obstruction is due to pancreatic disorders, the method is simple and easily accomplished. In those who have suffered trauma to the ducts, an end-to-end suture should be made if enough of the duct is available after excising the stricture. Often, however, little of the common hepatic duct is left, and in these cases we believe that our method is particularly applicable. The anastomosis should be made over a removable tube. The chief difficulties have arisen when the tube has come out of the duct too soon. We believe that it should be left in place for three months, in the hope that a permanent communication can be established and the supporting tube eliminated.

Lahey²¹ has written an excellent editorial on the subject of injuries to the common and hepatic bile ducts. He stresses the importance of early recognition of the injury and the need for repair by surgeons experienced in this field.

STOMACH

The relation between achlorhydria, polyposis and ultimate carcinoma of the stomach has been synchronized by Castle.²² Olson and Heck²³ studied the data available at the Mayo Clinic and found that only 2 of 63 patients with untreated pernicious anemia developed cancer of the stomach in an average of two years. Thirty-one patients were treated for their anemia, and 6 of these developed cancer of the stomach in an average of five and a half years. Thus, it appears that, with a better life expectancy from pernicious anemia, the ratio of cancer of the stomach in such cases will be much higher than it is in normal persons.

Bisgard and Overmiller²⁴ believe that radical resection is indicated in perforated cancer of the stomach. They have collected from the literature 100 cases in which the perforation was closed or tamponaded by omentum, 76 of these patients died. In fifteen resections for this complication, there were 2 fatalities. These authors believe that 50 per cent of the cancers of the stomach that perforate are resectable.

Engel²⁵ advocates the fashioning of a gastric pouch following total gastrectomy for cancer. Since some patients complain of not being able to take food in adequate quantities following total gastrectomy, his concept seems logical. The pouch is constructed by making a long anastomosis between the two limbs of the jejunum, starting just below the esophagojejunostomy. It has long been recognized that a liberal enteroenterostomy between the

afferent and efferent jejunal limbs is advantageous. The larger pouch may well be an asset and should be tried.

Gastrojejunal fistula has been discussed by Marshall.²⁶ He advocates a preliminary ileosigmoidostomy to eliminate regurgitation of intestinal contents into the stomach. Later the fistula is resected, preferably with the usual radical stomach resection for duodenal ulcer. In 14 patients, there was 1 death following the first stage.

Ransom²⁷ reports on 14 cases of gastrojejunal fistula treated as follows. Ten patients had the fistulas resected without radical operation for the original duodenal ulcer, with 1 death. There were good results in 4 cases and recurrence of duodenal ulcer symptoms in 5 cases, in 3 of which radical subtotal gastrectomy was performed. Four patients were subjected to radical operation at the time of resection of the fistula, and 1 of these failed to survive.

DUODENUM

Perforated duodenal ulcer is again discussed by Graham and Tovee.²⁸ Of 114 patients admitted in a fifteen-year period to a service of the Toronto General Hospital, 111 were operated on, with 7 fatalities, a mortality of 6 per cent. Three patients not operated on, for reasons that seemed justifiable, died. The ratio of males to females was 107/7. All the patients came from within a twenty-five-mile radius, and all had had recent perforations. The danger of long-distance transportation in such an emergency is stressed. Graham and Tovee urge proper preoperative preparation in patients who arrive in poor condition. All the perforations were closed with omental tabs held in place by three catgut sutures, on the theory that fibrinous sealing is the aim of operation. The age of the patients varied from sixteen to eighty-three years and averaged forty-seven years. These authors are inclined to believe that age is not too important as a factor in mortality. In 34 of 59 cases in which cultures were taken from the peritoneal cavity, no organisms were grown. Drainage of the abdominal cavity was used in only 14 cases. Spinal and Pentothal Sodium anesthesia is preferred. These authors are adamant in insisting on the danger of a more radical procedure than simple closure of the perforation.

Price and Lee²⁹ closed experimental perforations in dogs' stomachs with omental tabs. All the closures made by omentum with an intact blood supply were successful. In many of the cases in which the tamponade was made with free omental grafts, the grafts became necrotic and leakage occurred.

Gray and Sharpe³⁰ followed the course of 52 of 62 patients who had been operated on for massive hemorrhage from duodenal ulcer by the Devine exclusion procedure. Five per cent of the patients failed to survive the operation. Forty per cent of

the survivors had later symptoms. The older patients did better than the younger ones, 18 of 21 fifty years of age or under having later symptoms, whereas only 3 of 16 over fifty did so. These authors conclude that this procedure may be justifiable in the older age group. They admit that it is a poor operation for duodenal ulcer, since only 60 per cent of the 52 patients remained symptom-free during the period of observation.

Colp et al³¹ report the comparative immediate results in two series of patients subjected to subtotal gastrectomy for duodenal ulcer. In 79 patients operated on between July 1, 1937, and June 30, 1940, there was an operative mortality of 10 per cent, whereas in 94 patients operated on during the following three-year period, the mortality was 4 per cent. The authors believe that better management of the duodenal stump with preliminary and complementary jejunostomy accounted for the improvement in results.

Rienhoff³² reports his results in 260 patients operated on for duodenal ulcer and followed for two to ten years. Two hundred and four patients (78 per cent) were considered well. Of the latter, complications developed in 32 (15 per cent), 22 of whom were subjected to further surgery. Thirty patients (12 per cent) were considered improved, and 4 of these were reoperated on. Twenty-one patients (8 per cent) were classified as unimproved, and 3 of these were reoperated on. The percentage of patients who remained well was higher in those with lowered gastric acidity than in those whose acidity continued high. Twenty-three patients (9 per cent) of the entire series developed anastomotic or jejunal ulcers. Rienhoff states that half the distal stomach with the pylorus was removed in all the patients, a short-loop anticollic anastomosis being used. In over 75 per cent of the cases, the ulcer was not resected. The operative mortality in the first 100 cases was 5 per cent. There were no deaths in the last 160 patients operated on, but some of these operations were too recent for end-result studies.

Lahey³³ advises in some duodenal ulcer operations the use of a T tube in the common bile duct with a long arm through the papilla of Vater for ease of identification in difficult dissections. In his discussion of Rienhoff's paper, he brings out the likelihood of better results if the ulcer can be safely included in the resection. Marshall³⁴ believes that a more radical resection of the stomach than Rienhoff uses would result in fewer jejunal ulcers.

McKittrick, Moore and Warren³⁵ analyzed the gastric resections for ulcer in the Massachusetts General Hospital from 1936 to 1943. There were 2 deaths in 106 cases of gastric ulcer and 10 deaths in 218 cases of duodenal ulcer — an over-all operative mortality of 3.7 per cent. These authors stress the dangers that arise in management of the duodenal stump in duodenal ulcer and recommend more frequent use of a two-stage procedure. The Finsterer

subtotal gastrectomy for exclusion is done as the first stage, and the removal of the antrum and the first portion of the duodenum as the second stage six weeks later. St John³⁶ in his discussion of this paper reports the results in the Presbyterian Hospital, New York City between 1939 and 1943. The gastric and duodenal ulcer operations are grouped together, with an over-all mortality rate of 3.7 per cent in 299 cases.

Lannin³⁷ gives an excellent review of the development of the modern concept of adequate resection of the stomach for duodenal ulcer. Experimental work based on duodenal ulcers in dogs produced by the method of Code and Varco³⁸ showed that the only procedures that always cured these ulcers were gastrectomy with sacrifice of the distal two thirds of the stomach and the Finsterer exclusion operation with removal of the antral mucosa. These writers further show by their experiments that the anastomosis must be placed as close as possible to the ligament of Treitz. They give evidence that antecolic anastomosis results in jejunal ulcer in direct proportion to the length of the afferent loop. This is supported by a series of three hundred subtotal gastrectomies in patients with duodenal ulcer. With these features in mind, no anastomotic or jejunal ulcer has so far developed. They believe that this is due to three reasons: the distal two thirds of the stomach is sacrificed, no antral mucosa is left behind, and the anastomosis is made as near the duodenojejunal junction as is technically possible.

Dragstedt and Schafer³⁹ give a further report on the treatment of peptic ulcer by transthoracic vagus interruption. Thirteen patients with duodenal ulcer, 1 with gastric ulcer and 1 with gastrojejunal ulcer were treated by this method. Three of the patients with duodenal ulcer were later subjected to gastroenterostomy for persistent duodenal obstruction. All these patients were immediately relieved of their ulcer symptoms, since hypersecretion of gastric juice was eliminated, but 1 patient had a recurrence of symptoms after three months of relief. The patient with gastrojejunal ulcer required a prolonged medical regimen after vagus interruption and was only partially relieved of his symptoms.

Moore, Chapman, Schulz and Jones,⁴⁰ have been studying this attack on the ulcer problem at the Massachusetts General Hospital. Their preliminary report substantiates Dragstedt's claims. These patients are immediately relieved of ulcer pain. The procedure is particularly adaptable to the recurrent-ulcer group and may well supplant subtotal gastrectomy in cases of uncomplicated but intractable ulcer. The wisdom of using this operation for cicatricial stenosis of the duodenum is doubtful. It probably has a limited field in gastric ulcer owing to the high incidence of early cancer in these patients.

SMALL INTESTINE

Cleland⁴¹ measured the length of the small intestine in 100 cases at autopsy. It was impossible to determine that age, sex or disease had any bearing on the variations, which ranged from 4 to 11 meters. The physiologic processes of the subjects examined seemed undisturbed.

These data are particularly important to the clinician. Reports are often made on the successful removal of considerable lengths of the small bowel with apparent subsequent good health. On the other hand, patients may suffer a serious handicap from the loss of a relatively small segment of bowel. Occasionally this produces problems concerning nutrition, but the disturbance oftenest seen is one of persistent diarrhea. It is quite possible that the original length of the intestine in a given patient needing elimination of a segment of bowel may influence the postoperative course. A rapid intestinal rate of a functional type also plays a role in this problem.

Smith⁴² has analyzed the experience in the Presbyterian Hospital in 1000 cases of intubation with the Miller-Abbott tube, which was successfully used in 751 cases and failed in 219, with the records incomplete in 30. It was employed prophylactically in 151 lesions of the small bowel and postoperatively in 84, and prophylactically in 108 lesions of the large bowel and postoperatively in 15, 153 intubations were for diagnostic purposes. Two or three cubic centimeters of mercury in the balloon is advised to aid the passage of the tube through the pylorus. There were complications in 140 cases—trivial in 129 and serious in 11. The tube required replacement in 54 cases.

Deering,⁴³ in reporting on his experience with the double-lumen tube in 200 cases, points out that the effectiveness of Wangenstein suction on a single-lumen nasal tube must not be forgotten. He believes that the Miller-Abbott tube should be reserved for extensive distention of the small bowel, the simpler method being more adaptable to the prevention of postoperative ileus and the relief of high intestinal obstruction.

Garlock and Crohn⁴⁴ analyzed the results in 164 patients treated for regional ileitis and ileocolitis. In 65 patients, the ileum was transected proximally to the disease and the distal end was inverted and dropped free into the peritoneal cavity, this being followed by ileotransverse colostomy. There were no deaths following this procedure, and recurrence of symptoms required extirpation of the diseased segment in only 9 cases. One-stage resection was done in 55 patients, of whom 9 died and 9 had recurrences. Twenty-five patients had two-stage resections, with death in 3 cases and a recurrence in 8. In 19 cases of ileocolitis, there were 2 deaths and 3 cases with recurrence.

In 19 patients who were subjected to resection

for regional ileitis by Bockus,⁴⁵ 3 died and 9 developed recurrent disease.

Cave⁴⁶ had 3 deaths, all from perforation of the ileum, in a series of 23 patients with regional ileitis. One of these died preoperatively, 1 a year after operation and 1 two years after operation. Seven of 80 patients operated on for ulcerative colitis had involvement of the terminal ileum. Cave calls attention to a rare form of chronic inflammation that he has encountered once, with a successful outcome. In this type there is a fibrinous envelope surrounding the intestine, which causes obstruction by infolding of the mucous membrane from outside pressure. Relief was obtained by the removal of the encapsulating structure.

Two unusual double intussusceptions of the ileum have been reported.^{47, 48} Both cases were in boys, aged four and five years. The first patient following treatment for round worms developed intussusception of the ileum with a second loop extending into the original one. The second case was initiated by a lipoma in the wall of the ileum. The first patient recovered after reduction of the intussuscepted segments, and the second after resection and anastomosis.

Dearing et al.⁴⁹ present an interesting case history of a seventy-five-year-old man who was admitted with intermittent intestinal obstruction and weight loss. Study revealed a calculus in the ileum, which was successfully removed at operation. It weighed 70 gm, measured 5.5 by 5.5 cm, and consisted chiefly of calcium carbonate and calcium phosphate.

Stone⁵⁰ presents the results of studies on patients with massive melena. Of 72 patients varying in age from eleven months to seventy-nine years, 21 had a cause for the bleeding proved by examination, operation or autopsy, in 20 cases, a possible but not a definite cause was revealed, in 31 patients, no cause for melena could be found. Stone points out that the latter group of cases should be treated conservatively and future studies done. Exploratory laparotomy, he states, may be justified in a search for the cause in certain patients at a time of election.

In a study of cancer in the small intestine, Shallow, Eger and Carty⁵¹ brought out the fact that in routine autopsies such lesions are found in the colon thirty-six times as often as in the small bowel. To 269 cases found in the literature they added 38 cases from the records of the Jefferson Hospital, Philadelphia. Carcinoma was most frequent in the duodenum and sarcoma most frequent in the ileum. The operative mortality, which was 44 per cent, was highest in the lesions of the duodenum and lowest in those of the jejunum.

To the above cases may be added 21 cases of malignant tumors of the small intestine studied by Fraser⁵² in Glasgow. In his report, lesions of the duodenum were excluded and the ratio of carcinoma to sarcoma was 12/9.

Hanno and Mensh⁵³ report a case of intermittent massive melena of fourteen years' duration. The patient had been subjected to gastroenterostomy on an erroneous diagnosis. Bouts of hemorrhage continued and finally ended in death from acute anemia. Autopsy revealed as the cause of bleeding a leiomyoma of the jejunum 20 cm distal to the gastroenterostomy stoma.

Sibley⁵⁴ reviews the literature on Meckel's diverticulum and reports 10 cases from his own experience. Emphasis is placed on the high incidence of gastric mucosa found in these lesions and on the frequency of dyspepsia resulting from hypersecretion at this level in the gastrointestinal tract. He emphasizes that the possibility of this condition as a cause of abdominal pain is frequently overlooked. Gendel and Beaver⁵⁵ have successfully treated a patient with Meckel's diverticulum still attached to the umbilicus. This case was complicated by gastric mucosa and by a wood splinter in the diverticulum that caused intestinal obstruction. An incidental finding of early acute appendicitis seemed to play no recognizable role in the symptomatology. An additional case of Meckel's diverticulum containing calculi has been reported by Allen and Donaldson,⁵⁶ making a total of 11 recorded cases.

COLON

DeBakey and Carter⁵⁷ discuss penetrating wounds of the abdomen and bring out the fact that the mortality rate in World War I was 45 per cent, as compared with 15 to 20 per cent in World War II. They attribute these better results to three chief factors: ample supplies of whole blood and plasma, a larger number of well trained surgeons in the forward area, and the widespread use of exteriorization of colon wounds, routine proximal colostomy and proper drainage of the pelvis in wounds of the rectum. The authors lay too little emphasis on the effects of better selection and distribution of personnel by the Office of the Surgeon General.

Poth⁵⁸ has made an exhaustive report on collected data relating to the use of sulfasuxidine and sulfathalidine in surgery of the colon. The effect of these drugs in preoperative cleansing of the bowel has, in the opinion of many surgeons, proved to be a good adjunct to careful colonic surgery.

Newton and Blodgett⁵⁹ compare the results in two series of colon operations done at the Peter Bent Brigham Hospital. In 78 resections without the use of sulfasuxidine, there were complications in 45 and 15 deaths. In 36 patients treated preoperatively with sulfasuxidine, there were complications in 9 cases and 1 death following operation.

Bargen⁶⁰ has used both sulfasuxidine and sulfathalidine extensively in intestinal disease. He points out the advantage of the lower toxicity of sulfathalidine and reports that some patients sensi-

tive to sulfasuxidine tolerate sulfathalidine well. He believes, as we do, that sulfathalidine is the superior drug. It gives a better preparation of the bowel and is less apt to cause bleeding from the growth and nausea to the patient.

Coller and Vaughan⁶¹ report a series of 173 consecutive cases of carcinoma of the colon recently treated at the University of Michigan Hospital. Twenty-eight cases (16 per cent) were not resectable. Of the 145 cases considered operable, 28 (19 per cent) had gross metastases to the liver or peritoneum. There were 112 patients whose spread of disease appeared to be limited to the resectable nodal regions. In this group there was only 1 death, which followed an attempt to remove widespread disease. These authors preferred the two-stage attack on the right colon if the lesion was large or infected or produced obstruction and if the patient was debilitated. One-stage procedures were done on more favorable lesions of the right colon and in all other segments. Fourteen patients had the Rankin obstructive modification of the Mikulicz operation. All the others had primary anastomosis, which in 68 cases was of the aseptic and in 52 was of the open type. Delayed wound closure was employed when there was gross contamination or after the open method of anastomosis. Sulfonamides were not used in the peritoneal cavity. Transverse incisions with fine-wire closure and early ambulation are believed to have contributed to the good results.

White and Amendola⁶² report the results of colon resection for malignant disease in the Roosevelt Hospital, New York City. It appears that primary aseptic suture and proximal decompression resulted in half the deaths that occurred in modifications of the Mikulicz type of resection. These writers stress the shorter period of morbidity and the greater comfort to the patient in the primary anastomosis group.

Berson and Berger⁶³ found the incidence of multiple carcinomas of the colon to be 5 per cent of all their colonic lesions. Thirteen patients had two areas of carcinoma at the same time, and 3 had three areas. Polyps were present in 25 per cent of the patients having one area of carcinoma and in 38 per cent of those with multiple lesions. Sixty-seven per cent of the polyps in the multiple group had undergone malignant degeneration. These authors point out the need for thorough investigation of the entire colon and the importance of follow-up studies.

Pregnancy complicating carcinoma of the colon is discussed by Banner, Hunt and Dixon.⁶⁴ They found 62 cases in the literature and added 7 from the Mayo Clinic. They point out that the usual symptoms of carcinoma of the colon, such as nausea and constipation, are often associated with pregnancy and are therefore overlooked. They are impressed with the ease of delivery after abdominoperineal resection and the apparent safety of

cesarean section in the presence of a colostomy

Finn and Lord⁶⁵ report a case of carcinoma of the sigmoid with obstruction occurring in a thirty-one-year-old tripara who was in the sixth month of pregnancy. The lesion was treated by a three-stage procedure and the patient was successfully delivered at term.

Wangensteen⁶⁶ has anastomosed the colon to the rectal ampulla after resection in 24 patients for carcinoma of the rectum and rectosigmoid and in 3 patients for ulcerative colitis. There were 2 hospital deaths in the cancer group. He drains the pelvis posteriorly and expects a temporary fistula. The sphincter control was good in all cases. Three of the patients with cancer had local metastases to the liver, which were excised. Five of the 22 survivors had developed local pelvic recurrences at the time of the report. Wangenstein admits that fixed tumors require abdominoperineal resection.

Bacon⁶⁷ states that in 208 cases in which resection of the rectum was done for carcinoma he preserved the anal sphincter in 80 per cent. He has modified the combined abdominoperineal operation of Babcock to include preservation of the sphincter, and believes that this operation does not influence local recurrence provided that the muscles are not involved. He agrees with Babcock that perineal colostomy is superior to the abdominal type. His resectability rate was 81 per cent, and the mortality 5.5 per cent.

The increasing tendency to preserve the anal sphincter in carcinoma of the rectosigmoid and high rectum should be based on sound cancer surgery. One may make a low anastomosis and do Bacon's operation, or even extirpate the rectum through the perineal route with revision of the sphincter, under two conditions—in patients with early low-grade localized lesions at a suitable level and in those with an incurable spread of disease. Local recurrence is justifiable only in the latter group. The use of drainage to the pelvis incites a fistula, increases infection and produces subsequent stenosis of the suture line. If an adequate preparation is done before operation and the peritoneal reconstruction is made with room for adequate seepage of serum into the peritoneal cavity, the results without drainage are better.

Griffin, Barton and Meyer⁶⁸ found that volvulus of the sigmoid accounted for 8 per cent of the obstructions of the large bowel in a series of 458 cases admitted to the Cook County Hospital. Twenty-five records were analyzed in detail. There seemed to be two distinct types of sigmoid volvulus. There were 7 acute cases, mainly in young patients with an average of twenty-four hours of symptoms and no previous history of bowel disturbance. Eighteen cases were classified as subacute and were in the older age group. These patients were ill for an average of one hundred and two hours before admission, and many of them had had pre-

vious attacks. These authors call attention to a characteristic so-called "ace of spades" appearance in the roentgen-ray film after barium enema. The mortality in this series was 40 per cent. The authors stress early diagnosis and early resection and advise against conservative measures.

PANCREAS

Morton⁶⁹ has given an excellent discussion on acute pancreatitis. Two thirds of the cases are those of acute pancreatic edema, and 60 per cent of these are associated with lesions in the biliary tract. The serum amylase is always elevated early in this type of the disease. Conservative treatment is indicated, and the mortality is low. Recurrent attacks are frequent. After recovery from the acute phase the biliary system should be studied, and if gallstones are present, they should be removed. Pancreatic necrosis accounts for the other third of patients with acute pancreatic disturbance. In this type of case the serum amylase may not be elevated and the symptoms are severer. Morton believes that surgery should be undertaken to establish adequate drainage of the pancreatic area as early in the disease as is compatible with the patient's condition. All nine patients with this necrotizing type of pancreatitis who were treated conservatively died, whereas of those operated on for drainage 45 per cent recovered. Diabetes followed in a certain number of the recoveries. This author calls attention to the precipitation of acute pancreatic edema by operation for duodenal ulcer penetrating into the pancreas.

Shallow et al.⁷⁰ report a successful outcome in an extremely ill woman of fifty-five who had pancreatic necrosis of eight days' duration. In addition to a large pancreatic abscess, there were two abscess cavities in the quadrate lobe of the liver. They believe that penicillin and sulfadiazine aided in the recovery on the basis of the types of organisms cultured.

Ten patients with pancreatic collections operated on with recovery are reported by Pinkham.⁷¹ He discusses the differential diagnosis between so-called "true cysts," on the basis of proliferative changes due to neoplasm, hydatid disease, congenital defects and retention due to obstruction of pancreatic ducts, and "pseudocysts." The latter type should be referred to simply as collections secondary to pancreatic trauma, inflammation or necrosis.

Whipple⁷² records his results in pancreatoduodenectomy. He believes that the one-stage procedure has many advantages over his original two-stage operation. Twenty-two patients with cancer and 5 with calcification of the pancreas were subjected to radical operation. In 8 cases in which the two-stage operation was done there were 3 deaths, whereas in 19 one-stage procedures there were 6 deaths. A patient who had islet-cell carcinoma was apparently well five years after opera-

tion Whipple⁷ advises implanting the common duct in the jejunum, with implantation of the pancreatic duct slightly lower down. This avoids the possibility of bile leakage and eliminates the debated question concerning the importance of re-establishing pancreatic continuity with the gastrointestinal tract.

Orr and Walker⁷³ stress the relative infrequency of carcinoma of the duodenum and report a case of a successful Whipple procedure in one stage. They point out that most of the carcinomas in this region start in the ampulla of Vater and are improperly recorded as duodenal lesions.

Strode⁷⁴ reports a successful Whipple operation for carcinoma that was primary in a duodenal diverticulum.

Brunschwig et al⁷⁵ record a case of total pancreatectomy, total gastrectomy, total duodenectomy, splenectomy, left adrenalectomy and omentectomy in a diabetic patient fifty-three years of age. The patient required no increase in the amount of insulin used preoperatively. He died of widespread carcinomatosis three and a half months after operation.

CASE 32121

PRESENTATION OF CASE

A twenty-three-year-old woman was admitted to the hospital complaining of vaginal bleeding.

She was in the fourth month of pregnancy. Ten days before admission the fetus was said to have died, and six days later vaginal bleeding began and increased up to admission.

The past history revealed that the patient had been in good health until a year before admission. At that time she had a spontaneous abortion at about the third month of pregnancy. She had received a plasma transfusion.

On physical examination the patient was well developed and well nourished and in no acute discomfort. The heart and lungs were normal. The uterus showed enlargement consistent with a four months' pregnancy. There was a foul, blood-stained vaginal discharge.

The temperature was 101°F, the pulse 80, and the respirations 20. The blood pressure was 110 systolic, 50 diastolic.

The red-cell count was 4,240,000, with 12.2 gm of hemoglobin. The white-cell count was 21,400, with 86 per cent neutrophils, on smear, many band forms were seen and the platelets were decreased. On the first hospital day the sediment from a catheterized specimen of urine contained 25 red cells, an occasional white cell and 5 epithelial cells per high-power field.

Soon after admission the patient was sedated with codeine and aspirin and given 6 gm of sulfadiazine. Penicillin was ordered, 16,000 units every two hours. Later the dose was increased to 64,000 units every two hours. During the afternoon of the first hospital day the temperature rose to 105°F. She had a chill and a few hours later spontaneously passed a macerated fetus. Fifteen minutes afterward an ampule of Pituitrin was administered intravenously, and a half ampule at fifteen-minute intervals for two more doses. The placenta, which was yellow, friable and necrotic, was passed at the time of the second dose. Eleven milligrams of morphine were given. After the abortion the patient complained of severe chest pain. The blood pressure fell steadily

to a level of 40 systolic, 0 diastolic. An intravenous injection of dextrose in saline solution was begun, and 1 unit of plasma was given. The patient's condition improved somewhat, and the intravenous drip was continued. Four hours later she was found in shock, being only slightly responsive, with a blood pressure of 40 systolic, 0 diastolic, and a pulse of 120 to 150. Another unit of plasma was given, followed by a transfusion of whole blood. A few hours later another whole-blood transfusion was given.

During the second hospital day, the patient became more responsive. She complained of nausea and severe generalized aching. Despite continuous intravenous drip and hypodermoclysis, she remained dehydrated. The blood pressure rose to about 50 systolic, with a pulse of 145 that was of better quality. She remained oliguric, only 30 cc of urine being obtained by catheter during twenty-four hours. The urine was cloudy, light amber and acid and gave a + test for albumin. The quantity was insufficient for measurement of the specific gravity. There was no sugar or diacetic acid. The sediment contained a rare coarsely granular cast, a rare red cell, an occasional white cell, 5 round cells and 10 epithelial cells per high-power field. No crystals were seen. The urine was sterile. A marked generalized flush appeared, with definite circumoral pallor. She vomited about 150 cc of grayish material mixed with mucus. She manifested air hunger, the respirations being deep and sighing. She was not cyanotic. The lungs were clear. She was given a transfusion of Rh— blood, 3500 cc of fluid, 7 gm of sodium bicarbonate and 100 cc of cortical extract.

On the third hospital day, periorbital edema appeared but the lungs remained clear. The blood pressure rose to 80 systolic, 50 diastolic. The generalized erythema became more punctate. Mild air hunger persisted. There was marked epigastric tympany, with fullness. Peristalsis was sluggish but of normal pitch. A few drops of urine were obtained by catheter. The sediment contained many white cells and a few red cells per high-power field, there were no casts or crystals. The patient was alert. Herpes labialis appeared. Cystoscopy revealed a normal bladder containing no urine. Both ureters were easily catheterized but no urine was obtained. The ureteral catheters were left in place.

On the fourth hospital day the serum protein was 3.5 gm per 100 cc. A Schultz-Charlton test was negative. The patient became semicomatose, with fibrillary twitching of the entire body. A subconjunctival hemorrhage appeared in the right eye. Early on the fifth hospital day she had a severe generalized convulsion and expired.

DIFFERENTIAL DIAGNOSIS

DR. ARTHUR T. HERTIG * This case may be summarized as one of a young woman who had had no

*Pathologist, Boston Lying-in Hospital and Free Hospital for Women, Brookline.

previous full-term pregnancies but had had one previous miscarriage of spontaneous origin and who came in with a septic inevitable abortion in the fourth month of pregnancy. The first thing of interest is the fact that this spontaneous inevitable abortion was septic. That in itself is an extremely unusual fact. Very seldom do spontaneous abortions show a septic course. I assume that this was a spontaneous rather than an induced abortion and that she was febrile from it rather than from some other inflammatory process.

Another interesting factor is that the patient bled so soon after the fetus died. The latter event occurred about ten days before delivery, and she began to bleed six days later, four days prior to admission. Usually it takes longer after fetal death for the sequence of events resulting in abortion to take place. The most immediately interesting thing about this patient is that she delivered spontaneously and then required two ampules (2 cc) of intramuscular Pituitrin in divided doses to effect delivery of the placenta. Pituitrin was indicated since it is good obstetric procedure not to invade the uterus in a case of septic abortion because of the chance of spreading the infection.

The first thing of importance with respect to her death seems to me to be the fact that she reacted badly, almost immediately, to the administration of Pituitrin. It must be remembered too that there could have been other causes for the patient's going into shock, one being unrecognizable or undiagnosed rupture of a viscus, specifically a ruptured uterus. I take it that the clinicians involved were satisfied that the patient had no ruptured internal viscus. She certainly had no external bleeding or peritoneal signs to go with a ruptured uterus. Hence, I should say that in all probability she did not have a ruptured uterus, although that must be considered. My impression at this point is that the patient had profound Pituitrin shock and was one of the very rare persons sensitive to even moderate doses of this drug.

The next fact of importance is that prior to delivery a catheter specimen of urine contained 25 red cells per high-power field. Whether the red cells came as a result of the trauma of catheterization or whether she actually had a hematuria, I do not know. That is an important point to consider in view of the oliguria and anuria that developed later. A significant fact clinically is that she was in general shock from which she did not respond well despite intravenous fluid, plasma transfusion and two whole-blood transfusions. It is of interest to ask why she did not respond to an apparently adequate amount of fluid and blood in the absence of a ruptured viscus and in the absence of any profound loss of blood. These features help to make the diagnosis of Pituitrin shock.

The next point to inquire about is whether this patient was Rh—, and I assume that she was since

they gave Rh— blood on the third transfusion. If she was Rh—, the next thing to determine is whether she had been previously sensitized by the Rh factor either from a previous transfusion or by the previous pregnancy, which aborted at three or four months. So far as I know there are no examples of isoimmunization in an Rh— patient by a pregnancy that did not persist over three or four months. She may, however, have been given Rh+ blood on the two transfusions before the Rh— transfusion. Is there any information about that?

DR WADE VOLWILER: They were Rh+.

DR HERTIG: Then that is a possible factor in her death, namely, that she had been sensitized to Rh+ blood, developed agglutinins and reacted fatally on perhaps the second of the two transfusions. Were both of them Rh+?

DR VOLWILER: Yes.

DR TRACY B MALLORY: How long was the time interval between the first and the last transfusion?

DR VOLWILER: Not more than three days.

DR HERTIG: And the time interval between the first two was a matter of hours?

DR VOLWILER: Yes.

DR HERTIG: So on the basis of the history one can rule out reaction of the patient to Rh+ blood after sensitization. There had not been time for her to have become sensitized. Furthermore, she does not appear to have had an ordinary transfusion reaction.

The next point of clinical significance is the fact that she had oliguria, which progressed to almost complete anuria. In a pregnant patient who had previously been transfused that could suggest two things—transfusion reaction, which can largely be ruled out, and bilateral symmetrical cortical necrosis of the kidney. Renal cortical necrosis was probably brought on by severe prolonged ischemia, induced by Pituitrin sensitivity and resulting in contraction of the precapillary arterioles throughout the body, particularly the afferent and efferent arterioles of the kidney. Hence my diagnosis is bilateral symmetrical cortical necrosis of the kidney. The clinical course is typical. She died at about the average time, namely five days. I do not believe that she had a transfusion reaction, nor do I believe that she had a ruptured internal viscus. The profound, prolonged shock is difficult to evaluate.

DR MALLORY: Are there any questions or other diagnoses that anyone would like to suggest?

A PHYSICIAN: Could syphilis be connected with this story in any way?

DR MALLORY: I believe not. The Hinton test was negative.

DR W SCHIER WILSON: Were hematein crystals seen in the urine on any occasion?

DR MALLORY: There is no record of them.

DR HERTIG: In fact, it states that there were no crystals of any sort. I should have said that this case might possibly be one of sensitization or sen-

sitivity to a sulfonamide because of the fact that some persons are sensitive to such drugs and react to relatively small doses. The patient received 6 gm of sulfadiazine. Such patients, — that is, the few whom I have seen, — die on the average in five or

reminiscent of scores of cases that many of us saw overseas during the last couple of years and in which the pathologic lesion is entirely different from that Dr Hertig has suggested. Almost any patient with severe traumatic shock who has received multiple transfusions runs a considerable risk of dying with delayed anuria and a clinical picture that, so far as I can see, is indistinguishable from the late stages of this story.

The kidneys of this patient were slightly enlarged. The external surfaces were vaguely mottled, poorly defined purplish areas being separated by irregular yellow areas. The appearance of the cut surface was much more striking. The entire cortex was discolored. The major part of it was bright red, but there were scattered, irregular, yellow areas in the midst of the hemorrhage. Under low power, the cortex showed dark areas representing hemorrhage (Fig 1). These stopped abruptly at the junc-

FIGURE 1

six days with anuria. In my opinion, however, there should have been some evidence of sulfonamide crystals in the urine were this case one of sensitivity to one of these drugs.

CLINICAL DIAGNOSES

Spontaneous abortion with septicemia
Uremia

DR HERTIG'S DIAGNOSIS

Bilateral cortical necrosis of kidneys

ANATOMICAL DIAGNOSES

Symmetrical necrosis of renal cortex.

Infarction of adrenal gland, bilateral

Subinvolution of uterus

(Uremia)

PATHOLOGICAL DISCUSSION

DR MALLORY Except for the difference of sex and the presence of pregnancy this case is quite

FIGURE 2

tion between the cortex and pyramid. With higher power, the striking feature comprised the blood vessels. In a typical glomerulus and its afferent arteriole (Fig 2), the wall of the arteriole appeared black, it was completely necrotic, part of it solidly thrombosed and part having a lumen. The fibrin of the thrombus extended over into several of the loops of the glomerulus. The tubules were widely separated by hemorrhagic stroma. The adrenal glands weighed 40 gm and were completely necrotic, with hemorrhagic borders (Fig 3). The picture essentially is like that of the Waterhouse-Friderichsen syndrome. The arterioles in the capsules of the

adrenal glands were necrotic (Fig 4) The change is identical with that present in the kidneys

Dr Hertig's diagnosis of symmetrical cortical necrosis is substantiated, and as he pointed out, that is the usual lesion that one would expect in a patient who developed delayed uremia immediately after delivery The lesion that we saw with shock in Europe was entirely different There was no

the initial lesion was in the precapillary arterioles of the kidney The precapillary arterioles elsewhere in the body, whether in the bowel, adrenal gland or pituitary gland or elsewhere, also showed involvement The massive cortical necrosis was apparently due to retrograde or diffuse thrombosis of the small erect arteries, but the initial lesion began in the small precapillary arterioles Is that your impression?

DR. MALLORY I do not feel competent to express an opinion This is a fairly rare condition At the time Dr Hertig* reported his cases four years ago he was able to collect about 70 cases from the literature It is unquestionably not so rare as that suggests, because all of us know of unreported cases

FIGURE 3

necrosis of the cortex The degenerative changes were found in the lower part of the nephron, the ascending loop of Henle in particular and the tubules were filled with hemoglobin casts just as they are in a transfusion reaction

Have you any further comment Dr Hertig?

DR. HERTIG I have seen two cases like this One patient died on the fifth day, and the other on the eleventh day post partum The former case was exactly like the one presented here The patient who lived eleven days did so only by the heroic efforts of the house staff, who did several exsanguination transfusions The entire renal cortex of the latter case was necrotic, but instead of being mottled red and yellow, it had a brilliant orange-yellow border around the periphery of the kidney, with only minute areas of viable tissue left It is our impression from studying these cases that

FIGURE 4

It was first described in relation to pregnancy, and it is still seen much more frequently in relation to pregnancy than in any other condition It can occur in the male sex, and a condition that simulates it closely can be produced in animals by injecting a toxin derived from staphylococci, which have nothing to do with the genesis of the human lesion

DR. DONALD S. KING How much of a factor was the Pituitrin?

*Sheldon, W. H. and Hertig, A. T. Bilateral cortical necrosis of kidney. *Arch. Path.* 34: 856-874, 1942

DR MALLORY I do not feel capable of answering that Dr Hertig has said all that can be said

DR JAMES B TOWNSEND Have all the patients received Pituitrin?

DR HERTIG I do not know whether they have or not. Most cases, however, follow so-called "toxic separation" of the placenta. In this case the clinical picture was so striking immediately following administration of Pituitrin that the drug seems to have had something to do with it. We know of course that this drug does contain a pressor substance affecting blood vessels and hence could have been the stimulus which caused the generalized arteriolar spasm that resulted, among other things, in cortical necrosis.

DR TOWNSEND Was any organism obtained from the blood ante or post mortem?

DR MALLORY No

DR HERTIG It must be pointed out that most cases of this condition in pregnancy are associated with toxic separation of the placenta, the underlying pathology of which is an acute atheromatous degeneration of the small arterioles of the placental site. This causes decidual necrosis and separation of the placenta from hemorrhage.

DR BENJAMIN CASTLEMAN Was either of your cases as early in pregnancy as this?

DR HERTIG No, they were in the seventh and eighth months.

DR MALLORY Occasionally, as Dr Hertig has pointed out, vascular lesions are found in other spots of the body besides the kidney. We were able to obtain the pituitary gland and cut a number of sections of it, but we did not find any vascular lesions.

CASE 32122

PRESENTATION OF CASE

A twenty-nine-year-old unmarried woman, a stenographer, was admitted to the hospital complaining of dizziness, nausea and vomiting. There is doubt concerning the validity of the history, since it was obtained from the patient, who was extremely ill.

She was well until about five weeks previous to admission, when she began to have intermittent attacks of weakness and dizziness. These apparently did not increase in severity or frequency. Five days previous to admission, while sleeping, she was suddenly awakened by severe vertigo, followed by severe nausea and vomiting. Immediately after this episode she felt weak. She again returned to sleep, but a few hours later she was awakened by the same symptoms, which lasted for about an hour. The following morning she had another similar attack. A local doctor was called, who thought that it was a gastrointestinal upset but later consulted a neurologist, who advised hospitalization. The pa-

tient stated that about twenty-four hours after the onset of her illness she developed a blurring of vision when looking through both eyes but not when looking through one. During the twenty-four hours previous to admission the doctor had started slow digitalization by mouth, giving 0.1 gm every four hours. An undetermined amount of this was vomited. The patient gave no history of rheumatic fever, previous recent infection or the taking of drugs or medicine.

Physical examination revealed a pale woman in considerable distress who was retching and restless. The pupils were normal. The fundi showed questionable binasal blurring. There was no hemianopsia. The extraocular muscles were normal. The neck was questionably stiff. The neck veins were not engorged. The left border of the heart was percussed at the anterior axillary line. The sounds were distant. No thrills or murmurs were detected. The cardiac rhythm was irregular. The apical rate was 108, the peripheral 65. The diaphragm was higher than usual. A few moist rales were heard over both lung bases. The liver edge was palpated 3 cm below the right costal margin and was tender, otherwise the abdomen was negative. There was no ankle edema, and the dorsal-pedis pulsations were normal. Vaginal examination revealed tenderness of both lateral fornices, there were no masses or discharge. The reflexes were sluggish, and Babinski's sign was absent. There was no sensory impairment.

The temperature was 101.2°F, the pulse 56, and the respirations 20. The blood pressure was 92 systolic, 60 diastolic.

The white-cell count was 16,750, and the hemoglobin was 100 per cent (Sahli). The urine was normal. An electrocardiogram soon after admission showed auricular flutter, at a rate of 290. The QRS complexes were aberrant and slurred, occurring as a bigeminy at a rate of about 75. There was a question of 2:1 or 1:1 heart block alternating or of 4:1 heart block with ventricular premature beats as bigeminy.

A short time after admission the patient became flaccid, unconscious and cyanotic. The heart rate remained rapid and irregular. The blood pressure fell to 60 systolic, 40 diastolic. An electrocardiogram taken an hour after admission was similar to the first one, with occasional ventricular premature beats interrupting the rhythm. These originated from different foci in Lead 3. Special auricular Lead 1 showed short strips that appeared to confirm the diagnosis of auricular flutter. CF₁ and CF₂ showed upward deflections of the R waves.

Half an hour later 6 cc of Cedilanid was given intravenously. The patient remained unconscious, but the blood pressure rose to 90 systolic, 70 diastolic, and the heart rate slowed to 150. One and a half hours later an electrocardiogram showed questionable auricular flutter at a rate of about 300 but not a truly regular auricular or ventricular rate.

There was still a bigeminy of QRS complexes at about 70, with marked variation in conduction and especially aberrance of conduction in the second of the coupled beats.

Two hours after the administration of Cedilanid 12 gm of quinidine was administered over a period of four hours. An electrocardiogram taken three hours after the beginning of the course of quinidine showed P waves at a regular rate of 90, without relation to QRS complexes, which were wide and slurred, at a rate of 90 to 95. Ventricular premature beats were frequent, and there were occasional groups of them, all from different foci.

Eight hours after admission the blood pressure could not be obtained. The apical rate was regular at 160. An electrocardiogram showed paroxysmal ventricular tachycardia at a rate of 210. The patient expired three hours later, eleven hours after admission.

DIFFERENTIAL DIAGNOSIS

DR. HOWARD B. SPRAGUE. With only the information given us that could be obtained from the patient, we can hardly do more than make a reasonable catalogue of probabilities. It seems to me, in discussing the background of the one outstanding feature here, namely, the extremely abnormal ventricular rhythm, which started with auricular flutter with an intermittent aberrance of the ventricular complexes and finally passed into a true ventricular paroxysmal tachycardia or what one may call ventricular flutter, before death. Outstandingly ventricular paroxysmal tachycardia and this terminal rhythm, a ventricular flutter that passed over into true ventricular fibrillation, are found in relation to true ventricular fibrillation, with myocardial infarction, in digitalis intoxication and at times from digitalis plus quinidine and perhaps from quinidine alone. Obviously with a woman only twenty-nine years of age the first etiology seems to be highly unlikely, nor do we have evidence of toxic doses of digitalis or quinidine. The history starts, not particularly acutely, with attacks of weakness and dizziness of five weeks' duration. They were accompanied by vertigo, nausea and vomiting, which seem to me to be consistent with episodes of abnormal cardiac rhythm and cerebral anemia or perhaps with small embolic or thrombotic affairs in the cerebral circulation. Recently there had been some blurring of vision and probably a diplopia, but this could not be demonstrated as having an anatomic basis at the time of the examination. Simultaneously there was a questionable slight stiffness of the neck. All these findings can be explained by the mechanism I have mentioned. It also appears likely that the abnormal rhythm was at first and fundamentally an auricular tachycardia.

In analyzing the electrocardiogram, auricular waves appear to be present and there is an auricular flutter with probably aberrant ventricular responses

which increase in frequency to the point where they take off with an independent rhythm. There is evidence of a re-entry phenomenon, so that true ventricular paroxysmal tachycardia eventually ensues from the re-entrance of the abnormal beats.

There were on physical examination a big heart, a high diaphragm and an enlarged liver, but the neck veins were not engorged and there was slight fever, and some leukocytosis.

Let us return to the catalogue of probabilities — the conditions in which ventricular paroxysmal tachycardia occurs. I have mentioned coronary disease and digitalis intoxication. A few years ago, when heavy doses of digitalis were given, with rapid digitalization, this type of thing did occasionally occur, with fatal results. There is no history that this patient was receiving excessive medication before entering the hospital. Some patients do not know when they are receiving digitalis. I remember a patient with severe digitalis intoxication who denied the possibility of taking the drug. She said that she was taking "only a capsule of white powder." We examined one of these and found a digitalis pill hidden within. She had become toxic without knowing that she was taking digitalis. Quinidine may be a factor in producing this rhythm, although most of the evidence indicates that the way to treat it is by quinidine. About twenty years ago Davis and I¹ reported a case in which we believed that quinidine and digitalis were responsible, in the presence of bundle-branch block, for producing re-entry and fatal ventricular tachycardia. Hypertension is found as a cause, rarely rheumatic heart disease, but not infrequently the examiner finds no evidence of valvular disease in the case, since with these rhythms it is difficult to be sure of the auscultatory findings. Rarely thyrotoxicosis may produce it. It has been described in congenital heart disease with ventricular septal defects, and in the South American literature at least, it is described with gumma of the ventricular septum. Indeed, emphasis on pathology in the septum is rather prominent in autopsy reports of deaths associated with ventricular tachycardia.

One always mentions periarteritis nodosa in these pathological conferences, but I find no evidence for it, although it can do as bizarre things to the heart as does a tumor of the myocardium. An undiagnosable type of interstitial myocarditis or myocarditis of the Fiedler type might be possible, or abscess of the septum of the heart.

There have been, strange to say, cases described in young girls with nothing wrong but obesity. In one case an attempt at a weight reduction program was followed by ventricular paroxysmal tachycardia and death. In another case autopsy showed nothing but a minor fibrosis in the heart muscle. Intoxications from various drugs, chiefly the chlorinated hydrocarbons (carbon tetrachloride, ethyl chloride, tetrachlorethylene, chloroform and cyclopropane),

DR MALLORY I do not feel capable of answering that Dr Hertig has said all that can be said

DR JAMES B TOWNSEND Have all the patients received Pituitrin?

DR HERTIG I do not know whether they have or not. Most cases, however, follow so-called "toxic separation" of the placenta. In this case the clinical picture was so striking immediately following administration of Pituitrin that the drug seems to have had something to do with it. We know of course that this drug does contain a pressor substance affecting blood vessels and hence could have been the stimulus which caused the generalized arteriolar spasm that resulted, among other things, in cortical necrosis.

DR TOWNSEND Was any organism obtained from the blood ante or post mortem?

DR MALLORY No

DR HERTIG It must be pointed out that most cases of this condition in pregnancy are associated with toxic separation of the placenta, the underlying pathology of which is an acute atheromatous degeneration of the small arterioles of the placental site. This causes decidual necrosis and separation of the placenta from hemorrhage.

DR BENJAMIN CASTLEMAN Was either of your cases as early in pregnancy as this?

DR HERTIG No, they were in the seventh and eighth months.

DR MALLORY Occasionally, as Dr Hertig has pointed out, vascular lesions are found in other spots of the body besides the kidney. We were able to obtain the pituitary gland and cut a number of sections of it, but we did not find any vascular lesions.

CASE 32122

PRESENTATION OF CASE

A twenty-nine-year-old unmarried woman, a stenographer, was admitted to the hospital complaining of dizziness, nausea and vomiting. There is doubt concerning the validity of the history, since it was obtained from the patient, who was extremely ill.

She was well until about five weeks previous to admission, when she began to have intermittent attacks of weakness and dizziness. These apparently did not increase in severity or frequency. Five days previous to admission, while sleeping, she was suddenly awakened by severe vertigo, followed by severe nausea and vomiting. Immediately after this episode she felt weak. She again returned to sleep, but a few hours later she was awakened by the same symptoms, which lasted for about an hour. The following morning she had another similar attack. A local doctor was called, who thought that it was a gastrointestinal upset but later consulted a neurologist, who advised hospitalization. The pa-

tient stated that about twenty-four hours after the onset of her illness she developed a blurring of vision when looking through both eyes but not when looking through one. During the twenty-four hours previous to admission the doctor had started slow digitalization by mouth, giving 0.1 gm every four hours. An undetermined amount of this was vomited. The patient gave no history of rheumatic fever, previous recent infection or the taking of drugs or medicine.

Physical examination revealed a pale woman in considerable distress who was retching and restless. The pupils were normal. The fundi showed questionable binasal blurring. There was no hemianopsia. The extraocular muscles were normal. The neck was questionably stiff. The neck veins were not engorged. The left border of the heart was percussed at the anterior axillary line. The sounds were distant. No thrills or murmurs were detected. The cardiac rhythm was irregular. The apical rate was 108, the peripheral 65. The diaphragm was higher than usual. A few moist rales were heard over both lung bases. The liver edge was palpated 3 cm below the right costal margin and was tender, otherwise the abdomen was negative. There was no ankle edema, and the dorsal-pedis pulsations were normal. Vaginal examination revealed tenderness of both lateral fornices, there were no masses or discharge. The reflexes were sluggish, and Babinski's sign was absent. There was no sensory impairment.

The temperature was 101.2°F, the pulse 56, and the respirations 20. The blood pressure was 92 systolic, 60 diastolic.

The white-cell count was 16,750, and the hemoglobin was 100 per cent (Sahli). The urine was normal. An electrocardiogram soon after admission showed auricular flutter, at a rate of 290. The QRS complexes were aberrant and slurred, occurring as a bigeminy at a rate of about 75. There was a question of 2:1 or 1:1 heart block alternating or of 4:1 heart block with ventricular premature beats as bigeminy.

A short time after admission the patient became flaccid, unconscious and cyanotic. The heart rate remained rapid and irregular. The blood pressure fell to 60 systolic, 40 diastolic. An electrocardiogram taken an hour after admission was similar to the first one, with occasional ventricular premature beats interrupting the rhythm. These originated from different foci in Lead 3. Special auricular Lead 1 showed short strips that appeared to confirm the diagnosis of auricular flutter. CF₁ and CF₂ showed upward deflections of the R waves.

Half an hour later 6 cc of Cedilanid was given intravenously. The patient remained unconscious, but the blood pressure rose to 90 systolic, 70 diastolic, and the heart rate slowed to 150. One and a half hours later an electrocardiogram showed questionable auricular flutter at a rate of about 300 but not a truly regular auricular or ventricular rate.

There was still a bigeminy of QRS complexes at about 70, with marked variation in conduction and especially aberrance of conduction in the second of the coupled beats.

Two hours after the administration of Cedilanid 12 gm of quinidine was administered over a period of four hours. An electrocardiogram taken three hours after the beginning of the course of quinidine showed P waves at a regular rate of 90, without relation to QRS complexes, which were wide and slurred, at a rate of 90 to 95. Ventricular premature beats were frequent, and there were occasional groups of them, all from different foci.

Eight hours after admission the blood pressure could not be obtained. The apical rate was regular at 160. An electrocardiogram showed paroxysmal ventricular tachycardia at a rate of 210. The patient expired three hours later, eleven hours after admission.

DIFFERENTIAL DIAGNOSIS

DR. HOWARD B. SPRAGUE With only the information given us that could be obtained from the patient, we can hardly do more than make a reasonable catalogue of probabilities, it seems to me, in discussing the background of the one outstanding feature here, namely, the extremely abnormal ventricular rhythm, which started with auricular flutter with an intermittent aberrance of the ventricular complexes and finally passed into a true ventricular paroxysmal tachycardia or what one may call ventricular flutter, before death. Outstandingly ventricular paroxysmal tachycardia and this terminal rhythm, a ventricular flutter that passed over into true ventricular fibrillation, are found in relation to coronary-artery disease, with myocardial infarction, in digitalis intoxication and at times from digitalis plus quinidine and perhaps from quinidine alone. Obviously with a woman only twenty-nine years of age the first etiology seems to be highly unlikely, nor do we have evidence of toxic doses of digitalis or quinidine. The history starts, not particularly acutely, with attacks of weakness and dizziness of five weeks' duration. They were accompanied by vertigo, nausea and vomiting, which seem to me to be consistent with episodes of abnormal cardiac rhythm and cerebral anemia or perhaps with small embolic or thrombotic affairs in the cerebral circulation. Recently there had been some blurring of vision and probably a diplopia, but this could not be demonstrated as having an anatomic basis at the time of the examination. Simultaneously there was a questionable slight stiffness of the neck. All these findings can be explained by the mechanism I have mentioned. It also appears likely that the abnormal rhythm was at first and fundamentally an auricular tachycardia.

In analyzing the electrocardiogram, auricular waves appear to be present and there is an auricular flutter with probably aberrant ventricular responses

which increase in frequency to the point where they take off with an independent rhythm. There is evidence of a re-entry phenomenon, so that true ventricular paroxysmal tachycardia eventually ensues from the re-entrance of the abnormal beats.

There were on physical examination a big heart, a high diaphragm and an enlarged liver, but the neck veins were not engorged and there was slight fever and some leukocytosis.

Let us return to the catalogue of probabilities — the conditions in which ventricular paroxysmal tachycardia occurs. I have mentioned coronary disease and digitalis intoxication. A few years ago, when heavy doses of digitalis were given, with rapid digitalization, this type of thing did occasionally occur, with fatal results. There is no history that this patient was receiving excessive medication before entering the hospital. Some patients do not know when they are receiving digitalis. I remember a patient with severe digitalis intoxication who denied the possibility of taking the drug. She said that she was taking "only a capsule of white powder." We examined one of these and found a digitalis pill hidden within. She had become toxic without knowing that she was taking digitalis. Quinidine may be a factor in producing this rhythm, although most of the evidence indicates that the way to treat it is by quinidine. About twenty years ago Davis and I¹ reported a case in which we believed that quinidine and digitalis were responsible, in the presence of bundle-branch block, for producing re-entry and fatal ventricular tachycardia. Hypertension is found as a cause, rarely rheumatic heart disease, but not infrequently the examiner finds no evidence of valvular disease in the case, since with these rhythms it is difficult to be sure of the auscultatory findings. Rarely thyrotoxicosis may produce it. It has been described in congenital heart disease with ventricular septal defects, and in the South American literature at least, it is described with gumma of the ventricular septum. Indeed, emphasis on pathology in the septum is rather prominent in autopsy reports of deaths associated with ventricular tachycardia.

One always mentions periarteritis nodosa in these pathological conferences, but I find no evidence for it, although it can do as bizarre things to the heart as does a tumor of the myocardium. An undiagnosable type of interstitial myocarditis or myocarditis of the Fiedler type might be possible, or abscess of the septum of the heart.

There have been, strange to say, cases described in young girls with nothing wrong but obesity. In one case an attempt at a weight reduction program was followed by ventricular paroxysmal tachycardia and death. In another case autopsy showed nothing but a minor fibrosis in the heart muscle. Intoxications from various drugs, chiefly the chlorinated hydrocarbons (carbon tetrachloride, ethyl chloride, tetrachlorethylene, chloroform and cyclopropane),

may produce this type of rhythm. There is also the patient who has ventricular paroxysmal tachycardia in an apparently normal heart. At least those that die may show at autopsy a mild fibrosis of the myocardium. It has been described in cases of calcified pericardium.

Finally there are the diagnoses that one of my naval medical friends calls "those in the back of the book" which can be listed, but I find no leads for any of those diagnoses.

There is some evidence of infection, such as the fever, leukocytosis, tender fornices on vaginal examination, tender liver and high diaphragm. Isolated myocarditis, the Fiedler type, has been described following various infections, including gonorrheal infection. We have no evidence of that here, and no vaginal discharge. There may be some undiagnosable infection of the abdominal cavity, but I do not know where it is.

In conclusion I am going to say that all the ordinary probabilities seem to be absent in this particular case. The evidence is somewhat more in favor of infection of the myocardium of an unknown type. There may perhaps be a lesion of the septum. There should be an enlarged and dilated heart, perhaps more so on the right than on the left.

Was the head examined at autopsy?

DR MALLORY: No.

DR SPRAGUE: Small cerebral thrombi may have been present. The patient really died of shock.

I should be interested to know whether the clinicians did any better than I have in deciding on a diagnosis.

DR WADE VOLWILER: The clinicians did not do so well. The patient apparently had some cardiac disorder, but no murmurs were heard. She was sent into the hospital by her physician as a brain-tumor suspect because of the dizzy spells. On the way to the hospital he discovered the arrhythmia and started digitalis. The ventricular tachycardia appeared when we were giving large amounts of quinidine, and the question came up whether one should stop or give more quinidine. The opinion was that we should not give more since the arrhythmia was produced during quinidine administration.

DR SPRAGUE: The theory behind quinidine and digitalis poisoning, especially that due to quinidine, is that, in the presence of bundle-branch block, the conducting mechanism of the heart, which permits the ventricles to discharge synchronously and all over at once, is interfered with. This allows parts of the ventricle to recover from their refractory periods at different times, so that where an abnormal beat is propagated through the ventricle it may re-enter through an area in the muscle that has barely recovered, which in turn sets up a circus movement through the ventricle. It may be initiated by the use of digitalis or quinidine or the combination.

DR ROBERT S. PALMER: I should like to ask Dr Sprague if he thinks that a large heart like this and

tachycardia could occur in a twenty-nine-year-old woman in five weeks without some previous damage in the heart. Perhaps congenital sclerosis of the coronary vessels would produce it.

DR SPRAGUE: We have no evidence that anything was wrong with the heart previously. The enlargement may have been almost entirely due to dilatation.

CLINICAL DIAGNOSES

Cardiac arrhythmia

Auricular flutter changing to ventricular tachycardia

Cerebral embolus?

DR SPRAGUE'S DIAGNOSES

Acute myocarditis, with involvement of inter-ventricular septum, of unknown etiology (? Fiedler type)

(Auricular flutter)

(Ventricular tachycardia and flutter)

ANATOMICAL DIAGNOSES

Idiopathic acute myocarditis (? influenzal myocarditis).

Pulmonary emboli, multiple

Mural thrombi: right auricle and right ventricle

PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy on this patient showed a heart that was not hypertrophied and that was only moderately dilated. The liver was normal in size. The spleen was almost completely atrophic, weighing only 20 gm. The liver on section showed prominent central markings of the so-called "nutmeg" type. On opening the pulmonary artery, emboli were found in considerable number, and on going back to the heart, we found mural thrombi in the right auricle and right ventricle. The myocardium showed discoloration in numerous areas, particularly, as was prophesied, in the interventricular septum. This showed patchy gray spots that felt rather firmer than normal. Since the coronary arteries were completely normal, we strongly suspected that myocarditis was present. This was later confirmed microscopically.

This is a section of the myocardium (Fig 1). There are large areas from which the muscle cells have disappeared almost completely and in which only a few swollen hyalinized portions of fibers persist. Over to the right the fibers are still present but are obviously abnormal. The striations have been lost, there is central vacuolization in some, and they stain more intensely than normal. A rather striking feature of the section, which does not show in the photomicrograph because of inadequate magnification, is that some of these persistent muscle fibers contain a great many nuclei, sometimes five or ten in a single cell, much like the multinucleated giant cells one sees in degenerating skeletal muscle.

Mitotic figures are never found in muscle fibers after infancy, but the nuclei multiply amitotically by budding and fission. This occasionally occurs in heart muscle, but by no means so frequently as in striated voluntary muscle.

So we have here a severe myocarditis unassociated with proved infection anywhere else in the body. The valves were entirely negative. There was nothing in any of the organs to suggest rheumatic fever.

never personally seen such a case out of several score of cases of sulfonamide myocarditis. In my experience they have uniformly shown an interstitial myocarditis with little or no degeneration of the muscle fibers. I consider that a highly improbable etiology here.

One other cause of myocarditis was brought to our attention here in Boston a couple of years ago by Finland, Parker, Barnes and Jolliffe,³ who reported

FIGURE 1

It could be described and catalogued as "isolated," meaning merely that no other pathologic lesion was found in the body to account for it. An equally good term is "idiopathic," because, after all, we know nothing whatever of the etiology in a great many of these cases. Myocarditis does appear in a rather wide variety of infections, such as meningococcal and streptococcal infections, but only irregularly and infrequently. The only common causes of myocarditis are diphtheria and rheumatic fever. It is rare that rheumatic fever produces massive necrosis of muscle such as you see here. Diphtheria commonly does, but there is nothing in the history to permit us to suppose that this girl had diphtheria.

A form of myocarditis due to sulfonamide therapy has become well known to pathologists in the last three or four years. It has not attracted a great deal of clinical attention so far as I am aware. Myocarditis with extensive necrosis of muscle fibers has been attributed to sulfonamide injury.² I have

two cases of myocarditis immediately following infection with influenza A virus. Inasmuch as at the present time there is a mild epidemic of influenza A, it is a possibility in this case, perhaps the best guess one can make, but we have no proof of it.

DR SPRAGUE: As far back as 1921 Fiedler's myocarditis was described following influenza, so that it seems quite likely.

DR GEORGE C. COTZIAS: If it were trichinosis, would one have any difficulty in finding the organism?

DR MALLORY: One should have no difficulty in demonstrating the parasites in a case of this severity.

NEW A M A PROGRAM

THE new National Health Program of the American Medical Association and its scheme to establish minimum standards of acceptance for prepayment medical-care plans and to create a voluntary federation — Associated Medical Care Plans, Incorporated — are described in an editorial in the February 23 issue of the *Journal of the American Medical Association*, which should be thoughtfully read by all physicians

The National Health Program is a great improvement over the original fourteen-point program approved by the Board of Trustees last summer. Many of the obvious omissions in the latter, some of which were pointed out in an editorial appearing in the August 16 issue of the *Journal*, have been in-

cluded in the new program. Unfortunately, however, no reference is made to the need for improving the quality of medical care, in other words, it still seems to be taken for granted that all licensed physicians are equally well qualified to care for the sick.

Undoubtedly the standardization of medical-care plans will do much to ensure the success of such organizations, which in the past have enjoyed varying fortunes owing to a lack of sound actuarial data. Such figures are now becoming available, — for example, those concerning Massachusetts Medical Service, a pre-eminent successful venture, — and will be supplied by a new department of the American Medical Association — the Division of Prepayment Medical Care Plans — for the purpose of reorganizing nonacceptable plans or of creating new ones. One of the most significant steps is the formation of the voluntary federation, the chief aim being co-ordination of and reciprocity among all such medical-care plans. This should permit transference of subscribers from one plan to another and the rendering of service to subscribers outside their home states, all of which should encourage the acceptance of such plans by large national industrial organizations. Furthermore, a federation of this sort should be able to conduct a well co-ordinated and effective campaign of public education.

The American Medical Association appears to have initiated a constructive and promising program for improving the health of the Nation and for providing means of meeting the costs of medical care. It is to be hoped that this program will answer much of the criticism that has been directed at so-called "organized medicine" during the last few years.

"TO DO SOMETHING FOR THE WELFARE OF MANKIND"

THE twenty-seventh annual report of the Commonwealth Fund accounts for the spending of \$1,418,056. This sum is divided between the Fund's special programs and a group of more diverse and various grants. The largest amounts in the first category were appropriated in the interest of public health and the further extension of the now well known rural-hospital program. Another hospital

is to be constructed, in Sikeston, Missouri, and a new experiment in regional medical organization is planned for the area surrounding Rochester, New York. Smaller, but still significant amounts were devoted to mental health, education and publications. The special grants for medical research, war relief and miscellaneous purposes total \$677,457. By far the greater amount of the latter expenditures continued

to be for medical interests and activities. These are the items that appear at the end of the report, where they are often read first by those interested in where and how money is being awarded. It is probably intended, however, that a reading of the foreword precede indulgence in the gross figures of distribution.

As in previous reports, the foreword suggests why money is being spent where it is. It is a thumbnail essay on the difficulties and uncertainties that currently face medical practice and education. It contains several incisive observations, such as, "No short-cut to the integration of specialized knowledge into comprehensive medical care has yet been devised" and "the practical details for a coherent plan for the encouragement and support of research remain to be worked out." It is then recognized that these are serious questions and that they are not likely to be solved in financial terms alone. Although the foreword emphasizes that what the Fund can do is a small part of what must be done, it states the minimum objectives of the Fund as follows: sound training for professional and technical workers in strategic phases of health maintenance, the broadening and integration of the basic concepts of medical care so that it may become truly comprehensive, and the practical encouragement of human curiosity as the fountain-head from which medical knowledge renews itself.

The health of the Nation is a vast borderland between a philosophy and a discipline, between sociology and medicine. In it there are many mansions, some old ones with outworn and useless concepts, some new ones, unfinished and with untried architecture. There are other comfortable and livable houses in which the tenants have kept in touch with the practical realities of the world

and are contributing to the evolution of the human race. The Commonwealth Fund continues to house such tenants.

MASSACHUSETTS MEDICAL SOCIETY POSTWAR LOAN FUND

The Postwar Loan Fund has been set up, and all discharged medical officers who were members of the Massachusetts Medical Society in good standing at the time of their entry into the service may apply for loans from this fund. For further information apply to:

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

ALEXANDROV — Vitaly J. Alexandrov, M.D., of Rutland, died March 5. He was in his fifty-sixth year.

Dr. Alexandrov received his degree from Tufts College Medical School in 1930. He was born in Russia and graduated from the University of Moscow. He was consultant and medical director of the tuberculosis unit of Burbank

Hospital, Fitchburg, director of the Fitchburg Tuberculosis Clinic, and physician-in-charge of the Rutland Cottage Sanitarium. He was director of the Northern Worcester County Public Health Association. He was a fellow of the American College of Chest Physicians, the American Trudeau Society and the American Medical Association.

His widow, two daughters and two sons survive.

BURGESS — Charles J. Burgess, M.D., of Lawrence, died February 16. He was in his seventy-seventh year.

Dr. Burgess received his degree from Tufts College Medical School in 1898. He was a member of the Roentgen Ray Society and the Radiological Society of North America, Incorporated, and a fellow of the American Medical Association.

His widow survives.

SCENNA — Donato T. Scenna, M.D., of Melrose, died March 3. He was in his forty-second year.

Dr. Scenna received his degree from Tufts College Medical School in 1930.

His widow survives.

MEDICOLEGAL ABSTRACT

Regulation of Practice by Government Power of government. The plaintiff was incorporated as a nonprofit corporation. The corporation had three classes of members: administrators, practicing physicians and beneficiary members, who on pay-

ment of monthly dues, were entitled to the professional services of the participating physicians. It was provided that all compensation for doctors would be on a pro rata basis out of monthly dues. The corporation had about 5000 members in the second class and about 100,000 members in the third class, the latter was growing at a rate of 1500 members a month.

The plaintiff brought an action for a declaratory judgment to determine whether it was engaged in an illegal corporate practice of medicine and whether its activities were in the nature of disability insurance subject to certain sections of the insurance code.

On the first question, the California Supreme Court held that the prohibition against the corporate practice of medicine does not apply to nonprofit organizations. (The same doctrine has recently been expressed by way of implication in Texas where the court said by way of dictum that a corporation organized for profit cannot practice medicine and that a license to practice will issue only to a natural person — *Woodson v. Scott and White Hospital*, 186 S W [2d] 720, 1945, Texas).

On the second issue, the California court went into considerable detail in finding that the plan set forth did not constitute insurance. It found the group medical plan analogous to a consumer co-operative, saying in part:

Neither as between the corporation and the physician, nor as between the physician and the subscriber, is the compensation or any other element of the arrangement between them affected by any contingency, hazard or risk.

The latter [insurance companies] are concerned primarily, if not exclusively, with risk and the consequences of its descent, not with service or its extension in kind, quantity or distribution, with the unusual occurrence, not the daily routine of living. Hazard is predominant. On the other hand, the co-operative is concerned principally with getting service rendered to its members and doing so at lower prices made possible by quantity purchasing and economies in operation. Its primary purpose is to reduce cost rather than the risk of medical care, to broaden service to the individual in kind and quantity, to enlarge the number receiving it * * * not except incidentally * * * to indemnify for cost after the service is rendered.

In 1941 the plaintiff entered into a contract with the Federal Farm Security Administration to furnish medical services and hospital care to rural families. The state insurance commissioner attempted to show that the contract to provide hospitalization was insurance. For procedural reasons this question was not decided. The court did, however, say that a single aspect of a plan could not be singled out for condemnation, that the plan must be looked at as a whole, even though a contract to provide hospitalization, when viewed alone, would under some circumstances be insurance — (*California Physicians Service v. Garrison*, 155 P [2d] 885, Feb 15, 1945, rehearing denied Mar 17, 1945, hearing granted Apr 12, 1945).

NOTICES

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the New England Hospital for Women and Children will be held on Thursday, April 4, at 7 15 p m in the class of the Nurses' Residence. Dr Bertha Offenbach will speak on the subject "The Common Eye Diseases Among Children."

TUFTS MEDICAL ALUMNI ASSOCIATION

The annual dinner meeting of the Tufts Medical Alumni Association will be held on Wednesday, April 10, at Somerset Hotel, Boston. The committee on arrangements consists of Drs George W Holmes, Alton S Pope, Samuel Robins, A Warren Stearns, John J Todd, Edwin T Wyn and Harry Blotner.

The guest speaker will be Major General Norman T Kistler who will speak on the subject "American Medicine in World War II." A message will be read from President Harry Truman. Other speakers will include Dr Reginald F. president of the Massachusetts Medical Society, Dr Warren Stearns and Dr Dwight O'Hara, Dr A K Packer, professor of obstetrics, Dr Louis E Phaneuf, professor of gynecology, Dr Benjamin Sachs, professor of ophthalmology, and Dr Leonard Carmichael, president of Tufts College. William E Browne, professor of clinical surgery, will present.

PSYCHOSOMATIC BACKACHE*

MAJOR MORGAN SARGENT, M C, A U S †

ALTHOUGH in most discussions of backache there has been a tendency to stress the pathologic conditions that are present,¹ yet the fact that the symptoms may exist without definite disease or deformities is undoubtedly recognized by all who must deal with the problem.² In this paper, however, it is desired to suggest that the differential diagnosis of backache is incomplete without the consideration of psychogenic factors, for the latter are important not only as causes but also as contributing factors in cases of organic disease. The symptom of backache, like that of headache, is difficult to evaluate, and at times constitutes a minor form of malingering. Because of its frequency, particularly in military personnel, the symptom is often dismissed after casual and brief examination.

Backache is a relatively frequent complaint among patients suffering from anxiety states. An unusual opportunity has arisen in an Army Air Forces convalescent hospital, in which the primary mission is the treatment of cases of severe anxiety states, to examine large numbers of patients suffering from neurotic symptoms and incidentally complaining of backache.

These patients are for the most part men who have returned from combat tours in all parts of the world, and who on admission are suffering from symptoms of nervousness, insomnia, tension, irritability, restlessness, depression, startle reactions and other neurotic complaints. The causation and treatment of these conditions have been thoroughly described by Grinker and Spiegel.³ Most of these patients are former members of air crews. A few who are not fliers have had long periods of general duty in distant theaters. Their symptoms have been brought on by long separation from home, privation, loneliness and difficult climatic conditions. No patients have been seen in whom backache was the only complaint.

The patients complaining of backache seen in this hospital fall, with considerable overlapping, into three main groups. In the first group are those in whom definite organic disease is found. It has been the policy when dealing with backache to rule out every possible organic cause by careful

clinical examination, x-ray and laboratory studies and, when indicated, additional orthopedic consultation at a nearby Army Air Forces regional station hospital. The proportion of cases in which organic disease alone has been found is less than 4 per cent. The treatment of these cases is primarily an orthopedic problem, and as such has been handled separately from the psychiatric problem. In the second group are the cases with hysterical conversion symptoms. In this classification are included patients of two categories—those suffering from what is considered to be a simple hysterical conversion symptom, and those who have in the past had some evidence of organic disease and at the time of admission appear to be exaggerating their complaints or to have had excessive prolongation of symptoms. Few if any of the patients were thought to have symptoms of a purely hysterical conversion. Practically all those in this group gave a history of some previous injury to the back, often incurred many years previously, and the point of interest is that although many of them had had absolutely no difficulty for many years, they again developed symptoms concomitant with the onset of stress in their Army life.

The following case is illustrative of the way in which the nervous symptoms are held in check by the conversion symptoms. This patient had fallen down some steps twelve years previously, landing on the base of the spine. He believed that this had caused a permanent injury, and said that for the last three or four years he had had an intermittent low backache. On examination he complained of slight pain in the region of the lumbosacral joint on backward bending, but the examination was otherwise negative. X-ray examination of the lumbosacral spine and pelvis showed a small spina bifida occulta of the fifth lumbar vertebra but was otherwise negative. The patient made the interesting and wholly spontaneous statement that when his backache disappeared he experienced extreme anxiety.

Many other patients sustained injuries during combat that were followed by prolonged persistence of symptoms. In a typical case of this kind, the patient complained of backache in the lower dorsal and upper lumbar region, which took the form of

*From the Army Air Forces Convalescent Hospital (Don Ce-Sar) St. Petersburg, Florida.

†Associate surgeon, Quincy City Hospital (on leave of absence).

a dull ache most of the time and was aggravated by exercise and fatigue. On March 18, 1944, he was thrown against a tree by a bomb explosion, was said to have had fractures of the spine and was placed in a body cast for three months. On removal of the cast he was given a back brace, which he wore for the next nine months, although he felt little benefit from it. Since the injury he had been extremely nervous, and he told the examiner that his back bothered him most when he was "nervous." After his return to this country through medical channels, he was kept in various hospitals. Although his back was x-rayed many times, all available reports were completely negative and showed no evidence of old injuries. Examination in this hospital revealed slightly increased prominence of the spinous process of the eighth dorsal vertebra and tenderness over the spinous processes of the lower dorsal and upper lumbar vertebrae. There was considerable spasm of the paravertebral muscles, particularly on the right. Motions of the back were entirely normal. Treatment consisted of psychotherapy and exercises for the back, and the brace was discarded. The back symptoms improved somewhat, but the patient was eventually discharged from the Army on the basis of a severe anxiety reaction. His nervous symptoms had begun at the time of injury. It was impossible to find out what had happened to the patient's back at the time of the blast, since the accident occurred at an outlying base in the jungle and no records were sent with the patient. One can only surmise from the x-ray reports taken after removal of the cast either that there had been no actual fractures or that, if present, they were not too severe and healed without residual evidence. This patient was treated as a physical invalid for a year, during which time he tended to exhibit exaggerated symptoms. He also showed symptoms of backache due to muscular tension.

Another patient showing conversion symptoms was injured in a crash landing in July, 1944, being struck in the lower back by a piece of metal, which caused a contusion. After having his back strapped by his flight surgeon, he continued flying. In the following month, he was shot down, captured and interned in a neutral country, where he received no specific treatment. Since that time he had had a dull ache in the lower back, which after long standing or sitting extended up the paravertebral muscles. Examination at this hospital revealed diffuse and moderate tenderness in the lumbosacral area and over the lower sacrospinalis muscle groups, with moderate spasm of the muscles of the lower back. X-ray examination of the spine and pelvis showed slight roughening of the apophyseal articulations of the fifth lumbar and first sacral vertebrae, particularly on the left. Because of these findings, physiotherapy was given in the form of baking with infra-red rays and massage, but with no relief

of symptoms. Approximately one month after entering the hospital, the patient developed symptoms of acute appendicitis, and appendectomy was performed under spinal anesthesia. Throughout the operation the patient complained of pain in the lumbosacral area, and at its conclusion this complaint was investigated. The anesthesia, which had been completely satisfactory throughout the operation, was complete at least as high as the ninth dorsal vertebra, but the patient said that he still had an aching pain in the region of the lumbosacral joint. This was obviously impossible on a somatic basis. The symptoms exhibited were considered out of proportion to the extent of the injury, but the x-ray findings, although somewhat questionable, led us to give him the benefit of the doubt, and for several weeks it was believed that he had good reason for the discomfort. Incidentally, the backache improved considerably during the course of psychotherapeutic interviews.

Even superficial psychiatric examinations revealed that the patients whose backache was thought to be mostly a conversion symptom showed comparatively fewer symptoms of overt anxiety and nervousness. Practically all the patients in this group were enlisted men, and taken collectively they appeared to be somewhat less anxious than their associates. The fact that they were enlisted men is significant only in that the level of education of the group as a whole is lower than that of the officers.

By far the largest number of patients with backache fall into the third group of cases, which are considered functional in type, the backache being due to muscular tension, the somatic manifestation of increased nervous tension. These patients exhibited all the symptoms associated with operational fatigue. As a rule they were tense and nervous, complained of insomnia and combat dreams, and found it difficult to sit still for any length of time. The more restless they were, the severer the backache was. Most of them complained of aching pain in the lower lumbar or lumbosacral region, but others located their pain in the lower dorsal area and a few described it as in the upper dorsal or posterior cervical area. The backache is usually intermittent. The pain may not be felt for hours or even days, and it is most frequently complained of at night, early in the morning and after exercise or long standing or sitting. Although in the less acute cases an increase in muscular tension is not always demonstrable, in the severer cases it can be easily elicited by palpation, particularly in the sacrospinalis and erector spinae muscle groups, and at times the muscles go into almost boardlike spasms. Several patients have been seen in whom the back muscles were under such tension, even in a relaxed position, that fibrillary contractions were visible. These patients exhibit signs and symptoms of easy muscular fatigue, which is easily

noticeable among the severe cases and is partly proved by the poor showings made during tests of physical fitness. Consequently, it is believed that increased tension of muscles that are easily fatigued tends to cause symptoms far more easily than it does in more normal muscles. When demonstrable tension is present by palpation, there is often some limitation of forward bending, with an increase in pain, and there is some pain on straight leg raising and also on forward tilting of the pelvis with both flexed knees brought up toward the chest.

The signs and symptoms often vary in the same patient from day to day, as one would expect when the muscular tension is the result of nervous tension. Many of these patients have considerable difficulty in sleeping, and when once asleep they have combat and anxiety dreams that keep them tense and restless throughout the night. This is apparently the reason why so many patients complain of backache during the night and on awakening in the morning. The inability of the muscles to secure rest results in a constant state of fatigue, and it is small wonder that any additional burden placed on them by exercise or by long use in the maintenance of posture results in protest, which is manifested by pain and aches.

In contrast with the patients suffering from backache due to organic causes and with those with conversion symptoms, almost all patients with backache due to muscular tension complain of a rather diffuse ache, which they can localize only in the general region of the back. A large number of these patients attribute the onset of symptoms to some injury, but as a rule the injury is known not to have been severe, and at times evidence of it is almost nonexistent. This is illustrated by a patient who first noticed low lumbar backache in October, 1944, which developed after a burst of flak beneath the ball turret in which he was riding. At that time he was not injured, either by the flak or by concussion. On his admission to this hospital five months later, after completion of his combat tour, he complained of low lumbar backache, usually coming on in the morning, wearing off during the day and coming on again toward the evening. Examination of the back revealed an extreme degree of tension in the sacrospinalis muscle groups. X-ray examination of the lumbosacral spine was negative, and at the time of examination it was thought that the backache was a purely psychosomatic symptom due to muscular tension.

Another patient stated that off and on for fifteen years he had suffered low-back pain, which came on at times of excitement. He noticed this particularly while flying and when in a tight spot. There was no history of any injury. Examination revealed only marked spasm of both sacrospinalis groups.

Considerable difficulty exists in the correct evaluation of cases when the main problem seems to be muscular tension but careful examination reveals

some organic finding that may contribute to the picture. A typical case is that of a patient who suffered an injury to the lower back in December, 1943, when his plane was ditched. After a short period of disability he had little trouble until August, 1944, when he struck his back and strained it severely on falling from a catwalk into the bomb bay of a B-17. Since then he had had lumbar backache, present mostly when exercising. Examination of the back revealed moderate diffuse tenderness in the lumbosacral region and over the lower lumbar muscles. There was no postural deformity, and x-ray films of the spine were negative. Complaints of back pain continued and were greatly aggravated by a train ride while on furlough. It was believed that the patient might have chronic low-back strain but that most of the symptoms were psychosomatic in origin.

Another example of this type of patient is one who complained of low lumbar backache that first came on during his combat mission. There was no history of injury. On several occasions clinical examinations revealed nothing abnormal, but the patient said that his back ached most in the morning and late evening. X-ray examination showed some roughening between the apophyseal articulations of the fourth and fifth lumbar vertebrae. This was taken into account, but it was thought that the symptoms were due to muscular tension, which probably aggravated and perhaps made symptomatic the organic disease.

The pain in a great many of these cases is closely similar to that produced by protective muscle spasm in injuries of the lower back. Indeed, it is often of the same type, since it is generally believed that the pain of protective muscle spasm is caused by the persistent pull of muscles on their periosteal attachments. Therefore, in cases in which an injury such as a muscular or ligamentous sprain or strain has occurred within a period of eight to twelve weeks, one cannot say with any degree of certainty that the discomfort is not entirely of organic origin. In our opinion, however, without proved organic disease sufficient to cause it, the prolongation of such pain for several months is generally indicative of muscular tension arising from some other cause, presumably increased nervous tension.

Many cases have been encountered in which backache was undoubtedly due solely to tension, and in most of these cases the pain disappeared after a brief period of psychotherapy for the anxiety state. The discomfort of those with concomitant organic disease is often greatly relieved, but even with the combination of psychotherapy and orthopedic treatment the results are, quite understandably, not entirely satisfactory in all cases.

The treatment of patients with backache due to conversion symptoms or caused by increased muscular

lar tension must of necessity be primarily psychiatric. In patients with conversion symptoms, it has been found by experience that attempts to deal with the problem by means of physiotherapy, injections of novocain and medical measures tends to focus the patient's attention on the symptom and, if anything, to cause it to become fixed. The same thing is also true, perhaps to a lesser extent, of patients with backache due to muscular tension. Physical and medical procedures are only palliative. Physiotherapy can be carried on for weeks with temporary relief of discomfort for one or two hours after a treatment, or perhaps a little longer, but the symptoms invariably recur. Because of this, we believe that physiotherapy should be reserved for selected cases, usually those with definite organic difficulties, and that it should not be used for cases with conversion or purely tension symptoms. In this hospital the efforts of the Surgical Department to co-operate with the Neuropsychiatric Department have met with considerable success. These results have been accomplished, first, by ruling out the organic difficulties and reassuring the patient that nothing is being overlooked in the attempt to track down the cause of his symptoms, and, second, in preparing the patient for the full benefit of psychotherapy by endeavoring to explain to him in simple terms some of the causes of his backache.

Most of the patients with backache due to muscular tension reveal at some time during their examination the presence of some nervous symptoms, and a little careful questioning leads them to admit that they are more tense than they were previously. In this hospital, where the patients frequently climb upstairs to the various wards, they remark that their legs seem to tire considerably faster than previously or admit to easy muscular fatigue while engaging in exercise. Most of these patients also state that they have noticed an increase in general muscular tension in one form or another and that they find it difficult to relax. When these points have been demonstrated and the patients have perceived that they apply to themselves, it is pointed out to them that increased nervous tension causes increased muscular tension, and that since the muscles under such tension are seldom given a chance to relax as they would normally do, they are in a state of chronic fatigue, consequently, the

patients tire much more easily than usual when subjected to additional stress in the form of exercise, or even in the maintenance of posture when merely sitting or standing. Whether this is always the case may be debatable, but at least the point is understood by the lay mind. The fact that combat and anxiety dreams at night also cause much muscular tension is readily understood by those who experience them. With this brief explanation of the mechanisms involved, the patients are told that whereas they can be given temporary relief by such measures as heat and massage, this treatment is only temporary, and that the way to get permanent relief is to be relieved of the basic nervous tension. They are assured that this can be done by co-operation with the psychiatrist. In some patients this type of explanation seems to be sufficient in itself to cause a considerable decrease in symptoms, and in the majority it is believed that the way is paved for beneficial therapy of the primary condition by the psychiatrist.

SUMMARY

Backache is a frequent complaint among persons with anxiety states.

In a hospital where large numbers of men with anxiety states have been seen, the type of backache observed is due in most cases to hysterical conversion symptoms or to functional backache caused by muscular tension and fatigue. The latter type of backache is by far the most frequent one, but the two types are often associated.

Backaches caused by muscular tension and fatigue improve when the anxiety state is relieved by psychiatric treatment.

It is believed that pain of psychogenic origin should receive careful consideration in the differential diagnosis of any case of backache, especially since it may be closely associated with backache caused by organic disease and is often the cause of the prolongation of symptoms.

THE USE OF PHTHALYLSULFATHIAZOLE (SULFATHALIDINE) IN COLONIC SURGERY*

ROBERT THOMSON, M D,† AND ERNEST M DALAND, M D ‡

BOSTON

IN 1941, Poth and Knotts¹ introduced succinyl-sulfathiazole (sulfasuxidine) as an intestinal antiseptic and bacteriostatic agent. It has proved especially valuable as an adjunct to surgery of the large bowel, as well as in the treatment of certain medical conditions. A further improvement was made in this field with the discovery of phthalylsulfathiazole (sulfathalidine§) by Poth and Ross² in 1943. This new drug has the advantage of having twice the bacteriostatic activity of succinylsulfathiazole but requiring only half to one third of its dosage. In addition, the drug has not given rise to any toxic reactions such as have occasionally been seen with succinylsulfathiazole. Mattis et al.,³ in extensive toxicologic studies on the effect of phthalylsulfathiazole in mice, rats and monkeys, reported no toxic manifestations in spite of large doses administered orally every four hours for thirty days. They found extremely low blood concentrations of free and total sulfathiazole, which they attributed to retention in the gastrointestinal tract of all but small amounts of the drug, the small amount that was absorbed was rapidly excreted by the kidneys. Our studies of the blood and urine concentrations of this drug are in agreement with the findings of these investigators. Furthermore, phthalylsulfathiazole is effective in the presence of diarrhea or in patients who are receiving purgatives, whereas the effectiveness of succinylsulfathiazole under these conditions is greatly reduced.

The stools following the use of phthalylsulfathiazole are solid and retain some of their odor, as opposed to the odorless, semifluid movements that occur after the giving of succinylsulfathiazole. The exact mode of action of these drugs is not yet clearly understood. The chemical and bacteriostatic properties of phthalylsulfathiazole have been studied and reported by Poth and Ross.⁴

In this paper we are reporting our experience with the new drug at the Pondville Hospital, where it has been used in connection with surgery of the large bowel. It has been employed in the preoperative preparation of 51 unselected cases over a period of fifteen months. It has also been used in 12 cases of nonspecific gastroenteritis with diarrhea, in which it has apparently been of definite benefit. Our studies of the blood and urine concentrations of this

drug are in agreement with the findings of the above investigators.

The type of case in which phthalylsulfathiazole was used is shown in Table 1. In several of the cases the drug was used more than once, when the operation was done in stages. There was no evidence in any case of sensitivity to the preparation.

In Table 2 are shown the types of operation performed. There were 3 cases in the group given

Dosage and Preoperative Preparation

The routine procedure has been to place these patients on a low-residue diet and to begin the administration of phthalylsulfathiazole five or six days before operation. Giving the drug for shorter periods of time preoperatively proved unsatisfactory. It has, however, been given in full dosage for as long as fourteen days without any ill effect. The initial dose is 0.05 gm per kilogram of body weight, or between 2.5 and 4.5 gm for most patients. Following this, 1 gm (two tablets) is given every four hours day and night. Enemas are used preoperatively when indicated, strong purgatives are not employed. Whole blood, plasma and amino acid preparations are used as indicated in the correction of anemia and low serum protein. For twenty-four hours be-

Laboratory Data

Determinations of the blood and urine levels of phthalylsulfathiazole were made daily, as well as red-cell counts, white-cell counts and hemoglobin determinations, in the 19 cases listed in Table 3. No facilities were available for bacteriologic examination of the stools. Such studies have, however, been reported by Poth and Ross,⁵ and the effectiveness of phthalylsulfathiazole in reducing coliform and other organisms has been well established.

In Table 3, it will be noted that the daily dose as well as the number of doses varied, this was due to the fact that in these cases an attempt was made to adjust the dosage as accurately as possible to the patient's weight. In view, however, of the extremely

fore surgery the patient is given only clear liquids by mouth, and routine doses of sulfadiazine are administered during this period, either by mouth or intravenously.

At the time of operation, in all cases except 1 in which there was no obstruction, the bowel was found to be well cleaned out and free from distention. The exception was a case of unobstructed carcinoma of the rectum in which abdominoperineal resection was carried out after the patient had received phthalylsulfathiazole for only three days. In only 1 case, mentioned above, was the drug continued postoperatively, but it is thought that in many cases such continuation could and should be carried out. In support of this may be cited the case of a seventy-eight-year-old man in which a combined abdominoperineal resection was done in one stage after routine preparation. Four days postoperatively the end colostomy slipped back into the peritoneal cavity. The bowel was then retrieved and sutured to the abdominal wall. There was undoubted soiling of the peritoneal cavity, but the patient did not develop peritonitis. He was eventually discharged in a satisfactory condition.

low blood concentrations of the drug (measured as sulfathiazole) and in the absence of any toxic manifestations, the simpler routine was thereafter adopted of giving all patients 1 gm every four hours after the initial dose. In Cases 8 and 14, it will be noted that the blood level was appreciably higher than that in any other case, reaching levels of free drug of 2.040 and 2.681 mg per 100 cc, respectively. This is due to the fact that these patients were inadvertently given routine doses of sulfadiazine by mouth eighteen to twenty-four hours before these determinations were made.* The figures are interesting in that they show how little phthalylsulfathiazole is absorbed by the blood stream as compared with sulfadiazine.

Results

There were no toxic reactions from phthalylsulfathiazole in this series.

Among the 49 operative cases — fifty-two operations — in which phthalylsulfathiazole was used,

*The routine preoperative use of sulfadiazine as outlined in the section on preoperative preparation was not begun until after the data of the first 19 cases (Table 3) had been collected.

there were 4 cases (8 per cent) with infection. Three patients had wound infection and 1 developed generalized peritonitis and died, a mortality rate of 2 per cent. One of the patients with wound infection received an abdominoperineal resection. The end colostomy slipped back below the peritoneal floor on the fifth postoperative day, but it was almost immediately retrieved, and no peritonitis ensued. A similar accident occurred in another case in which wound infection developed, the mishap was not detected for eight to twelve hours. Colostomy was revised and the patient recovered. These 2 patients had received the drug for four and ten days, respectively, before operation.

The single operative fatality in this group occurred in a patient who had a two-stage operation for carcinoma of the splenic flexure. Following cecostomy, the patient received sulfathiazole for eight days before the second stage of the operation. Extension of the tumor necessitated partial resection of the stomach and splenectomy, as well as resection of the splenic flexure with primary anastomosis. The patient died three weeks postoperatively of peri-

tonitis. The effectiveness of the drug in this case was probably somewhat diminished by the presence of the cecostomy.

SUMMARY

Phthalylsulfathiazole, a new intestinal antiseptic and bacteriostatic agent, after its use in 51 cases was ranked as of definite value as an aid in surgery of the large bowel. Its small dosage, great bacteriostatic activity and low toxicity make it an easy, effective and safe drug to use. Continued use of the drug postoperatively, wherever possible, is advised.

CHRONIC DISABILITY IN MILD CASES OF TRENCH FOOT

MAJOR FRANKLIN K. PADDOCK, M C, A U S

RELATIVELY little study has been made of the persistent signs and symptoms of trench foot and immersion foot, most papers on this disorder dealing with their acute manifestations.^{1, 2} According to my experience, however, these symptoms may be disabling for at least one year and are apparently not alleviated by any of a variety of therapeutic measures, including psychiatric treatment. At the present time, with relatively large numbers of patients with this condition awaiting disposition at military hospitals in this country, such a study appears timely.

During February and March, 1945, in Italy, an opportunity was presented to study with special attention some of the manifestations of the later stages of trench foot. These cases, all of which were contracted in the Apennine Mountains of Italy during the winter of 1944-1945, were of mild to moderate severity and were on the whole less severe than those encountered during the preceding Italian winter campaign.

Since the later manifestations of trench foot are typified by subjective complaints most difficult to evaluate, an attempt was made to determine what abnormal responses, if any, could be elicited by various stimuli. In the cases studied, within one or two months after onset, the acute manifestations of edema and gangrene or pseudogangrene had disappeared and spontaneous pain, with tenderness of

the soles of the feet, was the chief complaint. The persisting disturbances fell into two main groups — the vascular type, characterized by a tendency to coldness and cyanosis of the feet, and the neural type, marked by pain on firm pressure over the soles of the feet, superficial hypalgesia, loss of proprioception, diminution of temperature discrimination, hyperhidrosis and poor toe-flexion ability.

VASCULAR DISTURBANCES

It is a frequent observation that patients suffering from the later stages of trench foot tend to have cold, sweaty feet that on dependency rapidly develop cyanosis. The following conclusions were reached from studies of this tendency.

When the shoes and socks of patients with trench foot are removed, the feet are found to be devoid of cyanosis, whether the patients have been stationary or moving about and even though the toe-skin temperatures are usually low (20° to 23°C). On dependency without the constricting-shoes and socks, however, cyanosis generally develops within five minutes. It can be made to disappear by elevating the feet, a normal pink color taking its place. Furthermore, on elevation the cyanotic hue can be readily milked out of the toes. If a uniform light-pressure bandage is applied to a toe when it is pink and the foot is placed in a dependent position, the bound toe is seen to be pink immedi-

ately following the removal of the bandage, even though the remaining toes have become cyanotic. When the foot vessels, either by direct or by reflex methods, have been brought toward full dilatation, as shown by a skin temperature of 30°C or higher, cyanosis does not appear on dependency so long as vasodilatation, as shown by the skin temperature, persists. With the return of vasoconstriction and cooling of the skin cyanosis develops. If the cyanotic toes are examined through a capillary microscope, it is found that gentle pressure with a glass slide eliminates the cyanosis without obliterating the visible capillaries.

An attempt was made to elicit the so-called "triple response" of the superficial vessels in the distal extensor surfaces of the feet both of normal persons and of those suffering from trench foot. In both groups, the local red response with surrounding pallor was usually obtained by firm stroking with a rounded point, but no wheal or flare was observed in either group. In addition, approximately 0.1 cc of a 1:1000 solution of histamine phosphate was injected intradermally over the mesial aspect of the first metatarsophalangeal joint of 2 normal persons and of 4 patients with trench foot. In each case a wheal with a surrounding flare of intense erythema appeared after approximately the same interval. This effect could not be reproduced in normal feet by a similar injection of normal saline solution. In the cases of trench foot, with the feet dependent and hence cyanotic, the zone of erythema stood out strikingly against the surrounding cyanotic skin. Simultaneous release of local pressure in both the cyanotic and the erythematous areas revealed a much more rapid return of color to the latter than to the former.

During the winter of 1943-1944, unilateral lumbar sympathetic block in 17 cases of trench foot brought about a prompt rise—within a half-hour—of the skin temperature of the foot on the affected side. This observation was verified in 2 cases during this study, the toe-skin temperature on the blocked side rising to above 30°C within a half-hour, with cessation of sweating. In 1 case so treated, the intradermal injection of 0.1 cc of 1:1000 histamine phosphate solution at the bases of both big toes at the height of the vasodilatation brought out prompt wheals with surrounding flares bilaterally.

Effects of Local Heat

The effects of local heat on cases of trench foot were studied by the following method. The left foot was placed in a specially constructed hot-water bath that allowed the foot to be submerged to the level of the malleoli but permitted the tip of the big toe to protrude through a rubber-lined opening so that skin temperatures could be taken. Since it was found by experiment that a minimum temperature of 39°C was necessary to bring about full vasodilatation, the bath was kept at a temperature

of 39 to 40°C by the addition of hot water. The left foot was kept in the bath until a toe-skin temperature of 30°C was obtained. When this had occurred, the foot was taken from the bath, dried and placed on a dry bath towel, and skin temperatures were taken at regular intervals for the next half-hour.

Various checks of this method were made. First, the temperature of the surrounding air was taken at regular intervals and found not to vary more than by 2 or 3°C during any single experimental period, usually being between 21 and 25°C. Secondly, the skin temperature of the right big toe was taken regularly at the same time as that of the left and was found to vary at most by 2 or 3°C. Thirdly, the skin temperature of the thumbs was taken periodically and was found to start at different levels and to vary markedly from patient to patient. No correlation, however, could be found between the temperature of the thumb and that of the left big toe. Fourthly, it was thought that the constriction of the left big toe by the rubber-lined opening might play a significant part in determining its temperature lability. Therefore in 2 cases that showed markedly delayed vasodilatation by this method, the foot was set in the hot-water bath with the water covering only the lower part of the foot, the tip of the big toe being above water level and free of constriction. The difference between the vasodilatation time obtained by this method and that obtained by the basic method was not significant. Furthermore, the factor of constriction was common to the normal controls and to the patients with trench foot thus tested. Fifthly, the skin-temperature measuring device* showed relatively slight variations when tested against a mercury thermometer. Skin temperatures, however, did show variations of as much as 0.5°C, depending on the exact spot on the toe tip tested. An attempt was therefore made to place the filament in as nearly the same spot as possible on each occasion. Lastly, the possible effects of emotional tension on the subjects' neurovascular tone were controlled as well as possible by personal acquaintance with the subject and by reassurance.

The feet of 11 normal persons and of 12 patients with trench foot were studied by this method. In the normal persons, a maximum period of forty-six minutes was required for the skin temperature of the left big toe to reach 30°C. In the cases of trench foot, however, there was a definite trend toward a prolonged vasodilatation time, more than fifty minutes being required to achieve a skin temperature of 30°C or over in half the cases. In 3 of these cases, furthermore, the toes did not reach this degree of temperature even after having been in the water for eighty minutes. These cases with prolonged vasodilatation time showed a good cor-

*Dermalog, manufactured by the McKesson Appliance Company, Toledo, Ohio.

relation with the tests of reflex vasodilatation (see below) in 3 out of 5 cases

When the feet were removed from the hot-water bath, no obvious differences occurred in the curves of skin temperature, which was tested over a half-hour period, between the patients and the controls

Reflex Effects of Heat

The reflex effects of heat were studied by the following method. The patient was surrounded by seven towel-wrapped chemical heating pads* — which may reach a temperature of 90°C — and was covered by six blankets. Both feet and the left hand were left uncovered. Every five minutes a recording was made of the room temperature, the oral temperature and the skin temperature of the left thumb and of both big toes. The test was considered satisfactory if the oral temperature rose by at least 1°F or a diffuse diaphoresis occurred within a half-hour period, or if both conditions obtained. If neither of these criteria was satisfied, the test was repeated on another day.

In the normal person, a skin temperature of above 30°C is said to occur in both thumbs and toes within a half-hour period. In 6 persons so tested, however, the skin temperatures of the big toes reached 30°C or higher in a maximum of forty-five minutes after the application of heat. For this reason, fifty minutes was taken as the upper limit of normal.

By this method 19 cases of trench foot were studied. In 6 of these, there was failure to reach the required skin temperature within a fifty-minute period, and in 2 of them as much as ninety-five minutes elapsed after the application of heat before this state was achieved.

* * *

The results of these various observations were interpreted as demonstrating certain abnormalities in the neurovascular mechanism of trench foot. It appears that the cyanosis of the feet that develops on dependency is apparently owing to stasis of blood on the venous side of the capillary loops, presumably in the subpapillary venous plexus, and that the cyanosis can be eliminated by an increase in the venous return, effected either by increasing the blood flow through arteriolar dilatation or by increasing the venous tone through extrinsic pressure. Some evidence was also obtained that the capillaries in these relatively mild cases of trench foot are intact.

The results of both the local and the central application of heat were interpreted as showing that at least the more superficial arterioles of the distal portions of the feet have increased tone. Since the paralysis of the sympathetic ganglions regulating those vessels leads to a prompt arteriolar dilatation, it may be assumed that the apparent

vascular disturbance lies in reality in the sympathetic nervous system, possibly in the autonomic nerve endings themselves, or that the mechanism is a simple reflex vasospasm such as has been demonstrated in response to painful stimuli. The hyperhidrosis may be taken as further evidence of excessive sympathetic activity.³ Furthermore, although pathological examinations of the amputated portions of the severer cases of trench and immersion foot have revealed vascular occlusions,^{4, 5} there was no evidence in the milder type of case included in this study that any significant intravascular obstruction was present, the arterioles being able to react completely, even if slowly, to appropriate stimuli.

NEURAL DISTURBANCES

Patients suffering from trench foot have difficulty in walking. In almost all cases this difficulty is primarily due to deep tenderness in the feet, which is most marked over the first metatarsophalangeal joint. The patient in placing his foot on the floor usually first throws his weight on the heel and then inverts his foot, so that the weight of the body as it moves forward is distributed along the lateral margin, the ball of the foot touching the ground last and only gently. The toes are generally held in a cocked-up position. The gait tends to be shuffling.

Neurologic examination of these feet in almost all cases reveals superficial hypalgesia to pinprick involving at least the flexor surface of the big toes. The more extensive areas of hypalgesia may have a narrow zone of hyperalgesia at their proximal border, and in an occasional case the superficial sensation of the whole distal portion of the foot is hyperalgesic. Hypesthesia or anesthesia to light touch is found too frequently in the toe tips of military personnel to admit comparison with cases of trench foot. Proprioception of the toes, as evidenced by position and vibration sense, may be diminished or absent. In 33 patients studied particularly for this phenomenon, 13 had poor position sense and 8 had absent vibratory sense of the big toes.

An occasional patient shows diminished or absent ability to flex the toes voluntarily. This has been noted in the earliest stages of trench foot while the patient was still bedridden. Of 33 patients with trench foot examined with this especially in mind 8 had poor toe-flexion ability. A more careful analysis of this disability indicates that the fault lies not in the short but rather the long flexor muscles, since flexion is absent in the distal rather than in the mesial or proximal phalanges. In all cases the toes could be flexed by the examiner with ease, and in most cases this caused no obvious discomfort. This disability showed no definite correlation with loss of proprioception sense but did show some correlation with the severity of the disease, being more frequent in the severer cases.

*Kemi therm, manufactured by the National Mineral Company, Chicago

Galvanic and faradic stimulation* of the long extensor and the long and short flexor muscles of the toes and faradic stimulation of the plantar nerve were carried out on 7 patients with trench foot, who showed diminished to absent ability to flex the toes. The same average quantity of ohms in the galvanic stimulation and of volts in the faradic stimulation brought the same threshold response in the patients with trench foot as it did in a similar number of normal persons. With these results in mind, 2 intelligent and co-operative patients with trench foot who had poor toe-flexion ability — one unilaterally — were given daily re-education in toe motion. At the end of five days both patients were able to flex the terminal phalanges of the big toes voluntarily. They had been in the hospital for sixty to ninety days at the time this experiment was tried without regaining this ability by themselves.

The ability to distinguish between hot and cold was tested. With the use of test tubes filled with warm and with cool water, with a temperature difference between them of 15 to 20° C, 21 normal persons and 14 patients with trench foot were examined, the test tubes being held for a maximum of five seconds against the area in and around the big toes. In all cases of trench foot so tested there was a loss of temperature sense in at least the tips of the big toes, whereas in the normal persons — except in 1 case complicated by marked toe callus — there was a ready ability to distinguish the temperature difference. In addition, a minority of the patients with trench foot had this loss at the base of the big toes on both the flexor and extensor surfaces. In all the cases of trench foot except 1, hypalgesia began proximal to the area of loss of temperature sensation. There seemed to be no correlation between proprioception and the extent of temperature loss, in that position sense might be present even when there was a loss of temperature sensation over the entire big toe.

An attempt was made to demonstrate the presence or absence of deep-seated sensitivity to cold in the distal portions of the foot in cases of trench foot. The subject was seated in a chair with the toes and ball of one foot and the fingers of one hand submerged in a pan of ice water. Since higher temperatures gave equivocal results in normal persons, the temperature of the water was kept at about 5°C. The members were kept submerged for a minimum of ninety seconds.

Ten patients with mild to moderate cases of trench foot and 10 normal persons were tested by this method. All the patients with trench foot complained of aching of the fingers within one minute, but only 1 complained of aching in the submerged portion of the foot. All the normal persons complained of aching of the foot, but in most cases the pain was confined to the areas of the metatarso-

phalangeal joints and was not of sufficient severity to make the subject withdraw his foot from the bath.

* * *

Either loss or exaggeration of superficial pain over the more distal portions of the feet appears to be common to all cases of trench foot. Loss of proprioception may occur in some cases, but deep pain sensation tends to persist. Loss or diminution of temperature sensation is a frequent finding. Since it is said that in a cooled nerve the sense of warmth is lost before that of coldness,⁶ it was hoped that these observations would help to distinguish between nerve damage caused by cooling and that caused by asphyxia. No conclusions in this regard, however, could be drawn.

It has been stated that the deep-seated aching due to cooling of an extremity is mediated by the small nonmyelinated nerve fibers of Class C.⁷ The absence of this pain in cases of trench foot is evidence that these fibers are damaged. Although the above study tends to show that such damage has occurred, the method is in essence dependent on subjective interpretations of pain and hence is not particularly valuable as a test for this condition.

The loss of voluntary toe flexion found in some cases is rather difficult to understand. The motor nerves and muscles show no obvious functional or structural abnormality. It seems likely that this disability is due to a disturbed toe-flexion pattern, perhaps lost during the earliest stages of the disease, when acute edema and vascular disturbance make toe motion painful.

PATHOLOGY

Scattered reports of the pathology of this condition are available in the literature.^{4, 5} In severe cases, gangrene with complete or partial vascular obstruction is obvious. Intense fibrosis and increased deposition of collagen have been described in severe cases of immersion foot.⁸

In 3 of the mild cases examined in this study, biopsy specimens of the tissues overlying the mesial aspect of the proximal phalanx of the big toe were taken. Microscopical examination† of sections stained with the Bodian protargol method revealed minor changes in the nerve trunks consisting of focal swelling of the axone cylinders. The nerves appeared to contain a comparatively large amount of fibrillar tissue for the location and the number of Schwann-cell nuclei. The vessels, corium and epidermis appeared normal, and there was no evidence of an increase in fibrosis or collagen or of a decrease in fat.

COMMENT

The chronic disability resulting from mild trench foot presents an interesting problem. In the early stages of the disease, damage to the blood vessels,

*This was done with the technical assistance of First Lieutenant Helen T. Lawrence, physiotherapist.

†These examinations were interpreted by Major Victor N. Tompkins, M.C. AUS.

resulting in inflammatory edema and a tendency to gangrene, overshadows the other aspects of the condition. When this phase has subsided, the patient is left with painful, tender feet that have a tendency to become cyanosed on dependency or exposure to cold. On gross examination in a warm room with the legs horizontal, the feet appear completely normal, and only on neurologic examination of the distal portions of the feet does any abnormality become apparent. When cyanosis is induced, vascular disease is at once assumed and is considered to be responsible for the disability. From the observations in this study, however, this does not appear to be the case, rather it is the terminal nerve twigs that are at fault—a terminal neuritis. Furthermore, one occasionally encounters a supposedly normal person whose extremities become cyanotic under similar conditions but who does not complain of any pain or tenderness such as that experienced by patients with trench foot. It is because neuritis is the underlying fault that, at least in my experience, interruption of the sympathetic pathways to the feet does not bring about frank relief of the symptoms, although it relieves the cyanotic tendency—and, of course, the associated hyperhidrosis.

On the basis of prolonged observation of these patients in the Mediterranean Theater of Operations, it has been found that the complaints of pain and tenderness clear extremely slowly. During the summer, hyperhidrosis, with resultant skin maceration and a tendency to epidermophytosis, was frequent. The pain and tenderness felt on walking was less during the warm weather, but even so prevented the sufferer from taking long marches. During the subsequent winter, a year after the onset of the disease, when the weather was cold and damp, spontaneous aching occurred and was associated with further diminution of walking ability, although not to its initial levels. It appears likely that this disability will disappear only after a period

of years and that therapy directed at the blood vessels and non-neural tissues will be of no avail.

SUMMARY AND CONCLUSIONS

A study was made of the later manifestations of trench foot of relatively mild severity.

A variety of related observations of the arterioles, capillaries and venules revealed that there was increased arteriolar tone, apparently secondary to increased sympathetic stimulation, but no evidence of arteriolar obstruction. The capillaries and venules were apparently normal.

Observations of the sensory and motor nerve disturbances revealed that besides superficial hypalgesia there was frequently diminution of temperature, vibration and position sense. Poor toe-flexion ability was shown to be owing to no obvious structural abnormality. Deep-seated sensitivity to cold tended to be absent.

The lesions of the less severe cases of trench foot are conceived of as involving all the more superficial foot tissues, but with a quantitative variation from patient to patient as regards the tissues affected. It appears that the disability encountered in the later stages of mild cases of this condition are more dependent on neural than on vascular disease. Microscopic examination of the damaged tissues tends to confirm this concept.

HEMORRHAGE FROM THE GALL BLADDER*

PERRY B HUDSON, M D,† AND PEER P JOHNSON, M D ‡

BEVERLY, MASSACHUSETTS

THE purpose of this paper is twofold—to present 4 cases of hemorrhage into or from the gall bladder, 3 of which had unusual features, and to show the significance of hemorrhage into the gastrointestinal tract in cases of cholelithiasis, as indicated by routine examination of the stools

Of the cases of massive hemorrhage from the gall bladder, 1 was due to neoplasm, so that the hemorrhage was not remarkable. The other 3 cases, however, are similar to the 24 already contained in the literature. This condition was first reported in 1892 by Naunyn,¹ who described 3 cases of ruptured arterial aneurysms causing massive hemorrhage into the gall bladder. In 1903, Huguein² reported a case of such a hemorrhage into the gall bladder and throughout the extrahepatic biliary duct system, but this was found to have been caused by carcinoma of the common duct. In 1915, Schnyder³ reviewed the literature and found 8 cases similar to those presented here, and added 2 of his own. In 1925, Heusser⁴ reported the case of a forty-seven-year-old man with cholelithiasis who developed massive hemorrhage into the lumen of the gall bladder. Perhaps the most remarkable case contained in the literature is that given by Fiessinger et al.⁵ His patient was a four-year-old child who developed massive idiopathic bleeding from a noninfected gall bladder that contained no stones. In 1939, Meyer-May⁶ reported a case of enormous hemorrhage into the gall bladder that was probably due to trauma incurred in a football game.

Another group of hematocholecysts found in the literature are those reported by Leared⁷ in 1858, Schnyder³ in 1915, Gjellerup⁸ in 1921, Waters⁹ in 1926, Bartlett and Bartlett¹⁰ in 1936 and Mailer¹¹ in 1939. In all these cases there was spontaneous rupture of the gall bladder, with considerable free intraperitoneal hemorrhage. Each case represented a mechanical tearing of the wall of the gall bladder secondary to blockage of the cystic duct. These cases, together with those of traumatic hemorrhagic cholecystitis, such as that described by Ireneus,¹² are not considered to be similar to the cases reviewed and reported elsewhere in this paper.

Hemorrhage into the gastrointestinal tract, as indicated by routine stool examination, is of importance in cases of cholelithiasis. In a number of patients in whom anemia is apparently the primary disease, little attention is directed to the biliary system. It has long been well known, if not fully appreciated, that a considerable percent-

age of patients with cholelithiasis have no marked abdominal symptoms or signs. A considerable number of them have blood in the stools, a point that is frequently neglected in the differential diagnosis. In reviewing our own cases, it was found that in 13 per cent of 100 consecutive cases of cholelithiasis brought to operation there was blood in varying amounts in the stools. In some of the cases there was concomitant disease, which may or may not have been the cause of melena. For instance, a patient had had a duodenal ulcer excised twenty-four years previous to admission for cholelithiasis. At the earlier admission, however, there was no blood in the stools. Another patient had diverticulosis of the colon, which may or may not have accounted for the presence of blood. Other disease, such as carcinoma of the breast, may be discounted as noncontributory to the finding of blood in the stools. In cholecystitis without cholelithiasis, 8 per cent of the cases with this finding in a series of 100 consecutive cases have been operated on at the Beverly Hospital in recent years.

CASE REPORTS

CASE 1 S S (No 54359), a 57-year-old, Jewish housewife, had had several previous hospital entries. Twenty-two years prior to admission she had a resection of the left ovary, left salpingectomy, right salpingo-oophorectomy, ventral fixation of the uterus, perineorrhaphy and dilatation and curettage. Fifteen years after the initial operation, she had a second perineorrhaphy and also an anterior colporrhaphy. Up to eight months prior to this admission the patient was in good general physical condition except for a 7-year history of occasional attacks of asthma. A careful history taking, however, revealed that as long as 1 year prior to admission she had had a sense of fullness in the epigastrium after eating. This usually occurred directly after taking a meal and was never accompanied by actual abdominal pain, although there was considerable gaseous distention. Some relief was obtained from the ingestion of sodium bicarbonate. There was no history of nausea, vomiting, jaundice, dark urine or tarry, bloody or clay-colored stools.

Eight months before the patient entered the hospital, she developed pain radiating from the substernal region to the back, especially on the left side, and extending into the arms. At that time a diagnosis of coronary disease was made and treatment was given accordingly. Shortly thereafter, because of an idiopathic anemia, the patient was given iron and liver therapy and placed on a special diet. One month later she began to have tarry or black stools. This may have been due to the oral administration of iron, because during 1 week of abstinence from iron the stools became brown. Four months later, during a stay at this hospital for bronchial asthma, hypertrophic arthritis, secondary anemia, possible gall-bladder disease and coronary insufficiency with healed myocardial infarct, the stools revealed a +++ test for occult blood, the reason for which was not immediately explained. A moderate secondary anemia with a hematocrit of 30 per cent quickly resulted. Extensive x-ray study of the gastrointestinal tract and gall bladder revealed no gastrointestinal cause for the melena, but the gall bladder was seen to be diseased. An attempt by an internist to determine the cause of secondary anemia following discharge also failed. Tenderness in the right upper quadrant of the abdomen,

*From the Department of Surgery, Beverly Hospital.

†Resident in surgery, Beverly Hospital.

‡Chief surgeon, Beverly Hospital.

unexplained melena and secondary anemia continued, the anemia progressing until the red-cell count was 2,000,000 and the hemoglobin 40 per cent. There were four admissions for transfusion only during the 2 months prior to the final admission. This procedure was necessary because the patient persistently refused an exploratory laparotomy that the surgical staff advised on the basis of x-ray evidence of gall-bladder disease, together with bleeding from the gastrointestinal tract.

Physical examination on admission revealed a well developed, somewhat obese, moderately ill, woman complaining of pain in the right upper quadrant of the abdomen. She was not cyanosed, dyspneic or jaundiced. The temperature was 101°F, the pulse 92, the respirations 22, and the blood pressure 140/80. The abdomen was slightly obese but not distended and contained a well healed scar low in the midline. The liver edge was palpable 3 fingerbreadths below the costal border at the right midclavicular line. Just below the liver edge there was felt a dome-shaped mass 2 cm in diameter that was exquisitely tender. The mass was freely movable but seemed to move synchronously with the liver on deep breathing. The kidneys were not palpable, nor was the spleen. No other masses were felt. No hernia was demonstrable. There was no appreciable rebound tenderness or muscle spasm.

The urine was essentially normal except for the presence of sugar. The hemoglobin was 55 per cent, the red-cell count 2,610,000, and the white-cell count 6350, with 77 per cent neutrophils, 21 per cent lymphocytes and 2 per cent monocytes. The reticulocyte count was 1.1. A blood smear was not remarkable. The total protein was 7.4 gm per 100 cc. The albumin-globulin ratio was 1.4. The blood nonprotein nitrogen was 34 mg per 100 cc, and the blood-sugar level 140 mg. The patient at that time was taking 40 units of regular insulin daily. The blood Hinton reaction was doubtful. The hematocrit was 32 per cent.

X-ray examination of the gastrointestinal tract was negative. Examination of the gall bladder after the administration of dye led to a diagnosis of pathologic gall bladder.

During the hospital stay the patient was transfused several times, beginning immediately after admission. On the 3rd hospital day, with a preoperative diagnosis of an abdominal mass in the right upper quadrant, of undetermined source and nature but probably malignant, mild, uncomplicated diabetes mellitus and unexplained melena, a laparotomy was performed through an incision in the right upper rectus muscle. The gall bladder was distended and filled with stones and large blood clots. The liver was enlarged but was otherwise not remarkable. Cholecystectomy and biopsy of the liver were carried out. The common duct was not explored. The patient was transfused after operation. Postoperatively the temperature spiked to 101.5°F on several days, but otherwise improvement was steady. The drain was removed on the 8th postoperative day, following which the temperature rose and a small wound abscess developed, a culture of which grew *Staphylococcus aureus*. Following this mild complication, recovery was uneventful. The diabetes was controlled fairly well with insulin and diet. The stools showed no further blood. The pathological report revealed chronic cholecystitis with cholelithiasis and a malignant hemangioendothelial sarcoma. Apparently this lesion had been removed in toto. There was no evidence of metastasis at operation and there has been no recurrence of symptoms, or anemia.

Comment. This case at first seems to support the belief that bleeding from the gall bladder is prone to occur in patients with vascular disease. The patient was diabetic, and although she had no marked external arteriosclerosis, there was a history of coronary insufficiency and she was at an age when diabetic arteriosclerosis begins to manifest itself. The presence of the hemangioendothelial sarcoma within the gall bladder, however, may well have accounted for the bleeding. This finding actually seems to exclude this case from the group of true hematocholecyts to which the other 3 cases presented here clearly belong.

CASE 2. D W (No 26893), a 30-year-old housewife, was admitted 9 years after an initial attack of severe epigastric pain. Other attacks subsequently occurred, and in all of them the pain was constant and acute in onset. A similar attack 6 months prior to admission had lasted for only 1 hour.

The present attack centered in the right upper quadrant of the abdomen, and the patient ascribed her symptoms to ice cream that she had eaten a few hours previously. She had vomited bile-colored fluid many times. She had never been jaundiced and had noticed no tarry or clay-colored stools or dark urine. She had passed no gross blood with stools.

Physical examination revealed an obese woman with acute distress in the upper abdomen. The temperature was 98.2°F, the pulse 76, and the respirations 20, and the blood pressure 120/80. The abdomen was obese but soft. There was marked tenderness in the right upper quadrant and throughout the entire epigastrium. There was no rebound tenderness, no palpable mass, and no hernia or other pathologic findings. Peristalsis was normal.

The urine was essentially normal. The hemoglobin was 97 per cent, the red-cell count 4,940,000, and the white-cell count 16,900 with 79 per cent neutrophils, 18 per cent lymphocytes, 2 per cent monocytes and 1 per cent eosinophils. The stool was brown and contained no blood. The icterus index was 8.2. The van den Bergh reaction was indirect. The bilirubin was less than 2 mg per 100 cc. A blood Hinton test was negative. In a test for urinary diastase, 32 cc. of starch solution was digested by 1 cc. of urine. The blood nonprotein nitrogen was 26 mg per 100 cc., and the blood sugar 80 mg.

Three days after admission, x-ray examination of the gall bladder following intravenous administration of dye revealed no concentration of dye. No stones were visible. An x-ray diagnosis of pathologic gall bladder was made.

On the 5th hospital day, with a preoperative diagnosis of acute cholecystitis and cholelithiasis, a laparotomy was performed under spinal anesthesia through an incision in the right upper rectus muscle. The gall bladder was moderately distended, and the mesentery was adherent to it. On aspiration of the gall bladder a large amount of fresh gross blood was obtained. There were several faceted stones and two ulcerations in the mucosa. No exploration of the common duct was carried out. The pathological diagnosis was the subsiding phase of a chronic recurrent cholecystitis and cholelithiasis, with formation of small ulcers. The postoperative course was uneventful, and the patient was discharged on the 15th postoperative day.

Comment. This case is probably typical of the cases of cholecystitis with cholelithiasis in which there is unexplained hemorrhage into the gall bladder. There was no blood dyscrasia and no known vascular disease, but microscopic sections of the extirpated gall bladder revealed marked sclerotic changes in the blood vessels.

CASE 3. H R (No E-4154), a 68-year-old housewife, was admitted with a chief complaint of acute epigastric pain radiating to the back. Pain had begun on the previous day. The patient had had "gall-bladder trouble" during the 24 years prior to admission. The attacks, which lasted for 10 to 15 minutes and occurred several times yearly, consisted of discomfort in the midepigastrium, with radiation of dull pain to the right costal margin and beneath the right shoulder blade. There was also a sensation of gaseous distention. Between attacks there was a slight degree of indigestion, characterized by gaseous distention following meals. The patient generally refrained from fatty foods but found that she could occasionally take fat in small amounts. There was no history of jaundice, dark urine or clay-colored or tarry stools prior to the most recent attack. There had never been chills.

Twelve years prior to admission the patient was seen at a diagnostic clinic, where she was told that she had "gall-bladder trouble." She was not operated on, since it was thought desirable to reduce the body weight, which was well over 200 pounds, before surgery was attempted. Six weeks before admission, she had an unusually severe attack, accompanied for the first time by mild nausea and vomiting. X-ray films taken elsewhere revealed impaired function of the gall bladder. There was no jaundice with the present attack, but the urine was mahogany-colored. The bowel movements had been scanty and clay-colored for the last few days. There was no history of diarrhea, blood in the stools or tarry stools.

Physical examination on admission revealed an obese

woman in moderate epigastric distress. There was a slight icteric tinge to the skin and scleras. The temperature was 98°F, the pulse 100, the respirations 20, and the blood pressure 186/104. The abdomen was soft and nontender. No masses were palpable in any quadrant, nor was there muscle spasm.

In a test for urinary diastase 4 cc of starch solution was digested by 1 cc of urine. The blood nonprotein nitrogen was 28 mg per 100 cc and the blood sugar 87 mg. The icterus index was 17. The van den Bergh reaction was immediate and indirect. The bilirubin was 2.89 mg. A blood Hinton test was negative. The prothrombin time was 35 seconds (normal, 17 seconds). The blood amylase was 45 mg per 100 cc. The stool revealed a +++ test for blood, and the vomitus a +++ test. The urine gave a ++ test for bile, the sediment contained a few red and white cells and bacteria. The hemoglobin was 71 per cent, the red-cell count 3,740,000, and the white-cell count 8400, with 68 per cent neutrophils, 30 per cent lymphocytes and 2 per cent monocytes. A blood smear was not remarkable.

The electrocardiogram was negative except for mild left-axis deviation, which was ascribed to left ventricular hypertrophy.

During the hospital stay there were recurrent attacks of nausea, vomiting and upper abdominal pain. Most of the stools contained blood. The bile disappeared from the urine 9 days after admission.

A preoperative diagnosis of chronic cholecystitis, cholelithiasis, choledocholithiasis and hemorrhage from the gall bladder was made. Under spinal anesthesia, a laparotomy was performed through an incision in the right upper rectus muscle, and an adherent gall bladder containing large clots of gross blood and numerous stones was removed. There were two ulcerations in its mucosa. The common duct contained three stones. The pancreas was normal. No other disease was found in the right upper quadrant of the abdomen. A T-tube was placed in the common duct, and a large amount of bile drained postoperatively. The postoperative course was uneventful, and the patient was discharged on the 23rd postoperative day. The pathological diagnosis was chronic and acute cholecystitis, cholelithiasis and blood clot in the gall bladder. There was no evidence of malignancy.

Comment. This case was remarkable in that extensive studies were undertaken to determine the exact cause of bloody stools that coexisted with known cholelithiasis and cholecystitis. By a process of exclusion, the only feasible explanation for the presence of blood in the stools was bleeding from the gall bladder, so that this diagnosis was made preoperatively. Such a diagnosis is highly unusual in the medical literature on this subject.

This patient suffered from hypertensive and arteriosclerotic heart disease of a mild sort, and it is known that bleeding from the gall bladder is likely to occur in patients with arterial and venous disease. Heusser¹ points out that the real reason for hemorrhage from the gall bladder is probably intrinsic pathologic changes in blood vessels rather than direct or mechanical erosion of the vessels by stones. Microscopic studies of this case seemed to confirm this theory.

CASE 4. W. C. (No. J-4033), a 44-year-old man was admitted with a history of attacks of sharp pain in the right side of the chest, accompanied by nausea and four spells of vomiting, of 5 days' duration. The vomitus consisted of undigested particles of food. Following the pain in the chest there was dull pain in the right upper quadrant of the abdomen, which persisted and became worse shortly before admission. During the 48 hours prior to admission, the nausea and vomiting subsided. The patient had been treated, for 3 days by his local physician, the treatment consisting of bed rest and nothing by mouth except whisky and water. The patient had never been jaundiced and had never noticed clay-colored, tarry or bloody stools. His past history revealed nothing remarkable except constipation during the week prior to admission. There had been no previous surgical operations or hospitalizations.

Physical examination on admission revealed a stocky, well developed and well nourished middle-aged man in mild upper abdominal distress. He was alert and co-operative and was not cyanotic, dyspneic or jaundiced. The temperature was 99°F, the pulse 88, the respirations 20, and the blood pressure 152/82. The heart was enlarged to the left

and downward. The apex impulse was felt in the 6th intercostal space outside the midclavicular line. The heart sounds were of good quality, and the rate was regular. There were no thrills or murmurs. The abdomen was obese. There was exquisite tenderness around the region of the gall bladder in the right upper quadrant, where a large mass, assumed to be a distended gall bladder, was readily palpated. The spleen and kidneys were not felt. There was no evidence of hernia. Peristalsis was normal. The rest of the abdomen was soft and nontender. There was no demonstrable fluid. An admission diagnosis of subsiding acute cholecystitis and cholelithiasis was made.

The urinalysis was negative except for the presence of 30 to 40 white cells per high-power field in the sediment. The red-cell count was 5,030,000 and the hemoglobin 97 per cent. The white-cell count was 10,350, with 79 per cent neutrophils, 16 per cent lymphocytes, 2 per cent monocytes and 3 per cent eosinophils. A blood smear was not remarkable. Examination of the stool revealed mucus but no blood. A blood Hinton test was negative. The nonprotein nitrogen was 28 mg per 100 cc, the blood sugar 77 and the vitamin C level 0.35 mg. The total protein was 5.9 gm per 100 cc, the fibrinogen being 0.7 gm, globulin 2.1 gm and the albumin 3.1 gm, an albumin-globulin ratio of 1.5.

X-ray examination confirmed the presence of gallstones, and on the 3rd hospital day, under spinal anesthesia, the abdomen was opened through an incision in the right upper rectus muscle. The gall bladder was found to be greatly distended, and stones were palpated in it. There were no ulcerations in the serosa. Cholecystectomy was carried out without undue difficulty, and the patient had an uneventful postoperative recovery until the 4th postoperative day, when the lower end of the rectus incision opened and there was a slight eversion of omentum through the wound. Resuturing was immediately carried out under spinal anesthesia. Following this, no further complications developed, and the temperature did not rise above 99.6°F after the second operation.

When the gall bladder was opened following operation, it was found to contain several clots and a massive hemorrhage. There were also present the pathologic changes suggestive of chronic and acute cholecystitis, as well as gallstones. A pathological diagnosis of bleeding gall bladder revealing a marked chronic and acute inflammatory process was made. The microscopic examination of sections from the gall bladder revealed the mucosa to be swollen and edematous and the blood vessels to be markedly dilated. The sclerotic changes in the vessels described in Cases 2 and 3 were present but not marked.

SUMMARY

The literature on hemorrhage of the gall bladder is briefly reviewed, and 3 cases of idiopathic hemorrhage are reported. A case of hemorrhage from hemangioendothelial sarcoma of the gall bladder is also described.

It seems quite likely, after reviewing our operative cases and those collected from other workers, that sclerotic changes in the vessels of the gall bladder are the underlying cause of such hemorrhage. Mechanical irritation from stones seems to be a secondary consideration.

The only lesson to be learned from these case studies is that more attention should be directed to the finding of blood in the stools of patients in whom cholelithiasis has not been excluded. It is probable that many cases of unexplained secondary anemia or of blood in the stools are due to cholelithiasis.

CLINICAL NOTE

SENSITIVITY TO TINCTURE OF MERTHIOLATE

CAPTAIN LESTER LIPSON, M C, A U S

TINCTURE of Merthiolate is widely used as a skin antiseptic and a preoperative preparation. This tincture is a 1:1000 alcohol acetone aqueous solution of sodium ethyl mercurithiosalicylate. Sensitivity to it is rare, but because this may occur and cause a disabling dermatologic complication, the present report seems justified.

CASE REPORT

A 21-year-old soldier was admitted to the 101st General Hospital on April 14, 1945. Three weeks previously, he had fallen from a vehicle suffering abrasions of both knees. After 5 days of self-treatment by dressing the abrasions with his first-aid packet, without noticeable improvement, the patient reported to the dispensary, where the abrasions were painted with Tincture of Merthiolate. This treatment was repeated daily for 5 days, by which time the skin had blistered, so that the treatment was stopped. The skin lesions, however, became more disabling during the next few days, and the patient was sent to this hospital. As a civilian he had had numerous attacks of poison-ivy dermatitis.

At physical examination the patient did not appear to be seriously ill. The extensor surfaces of both knees and the adjacent thigh and leg areas were the sites of a secondary infected dermatitis. There were many blebs and bullae, filled with serous or purulent fluid, and inflammatory erythema and induration were present throughout the area of involvement.

Patch tests were done in the usual manner on the flexor surfaces of the forearm with the following substances: Tincture of Merthiolate, aqueous Merthiolate solution, alcohol, acetone, Tincture of Metaphen (4-nitro-anhydro-hydroxy-mercury-ortho cresol), aqueous solution of Mercurochrome (dihrom-oxy-mercuri-fluorescein-sodium), and mercurial ointment (30 per cent metallic mercury). In the test with Tincture of Merthiolate, the patch had to be removed in 12 hours because of severe pruritus. The reaction exactly mimicked the lesions on the knees, showing blebs, vesicles and induration, and it spread to involve an area five times the size of the patch. Two weeks later, evidence of the reaction still remained (Fig 1). A reaction of equal severity resulted from

the test with the aqueous solution of Merthiolate. All the other patch tests were negative after 48 hours.

The lesions were treated as those of a pyoderma and cleared up without difficulty. Considerable discoloration persisted.

The material used for the patch test, which was performed in England, was not the same as that originally applied to the knees. The mercurials other than Merthiolate elicited no reaction and the tests with acetone and alcohol were similarly negative. All the tests were applied to areas not pre-

FIGURE 1 Photograph of the Reaction
This photograph was taken two weeks after the patch test with Tincture of Merthiolate had been applied.

viously treated by any other drug. One must conclude that the sensitivity was due specifically to Merthiolate, since there were positive reactions both to the tincture and to the aqueous solution.

SUMMARY

An unusual case of skin sensitivity to Merthiolate is presented. No sensitivity to other mercurials could be demonstrated. Because of the widespread use of this skin antiseptic, the possibility of such sensitivity should be kept in mind.

MEDICAL PROGRESS

DIABETES MELLITUS

ELLIOTT P JOSLIN, M D *

BOSTON

THIS review of progress in diabetes mellitus will consider advances in knowledge concerning alloxan and carbohydrate metabolism, recent papers on diabetic neuropathy, two articles dealing respectively with diabetes in children and with facts concerning the disease in Finland and, finally, associations, societies, foundations and trusts primarily interested in the problems brought about by this disease

ALLOXAN

Duff,¹ a well informed scientific investigator whose opinion is greatly respected and whose review of the pathology of the pancreas in experimental diabetes mellitus is most complete, makes the following statement "It is most improbable at present that alloxan plays a role in the etiology of human diabetes" Despite this assertion, I cannot escape the clinical conviction that the discovery of the specific action of this substance in destroying the beta cells of the islands of Langerhans has brought medical scientists nearer to the explanation of diabetes than has any step made hitherto — including partial pancreatectomy and the injection of anterior-pituitary extract Since the progress reports of 1944 and 1945 in this journal,^{2, 3} distinct advances have been made in the knowledge of alloxan that strengthen this belief More and more the specificity of its action in animals and birds has been confirmed Although in the human body alloxan has not been demonstrated in metabolic processes, particularly that of uric acid, from which it can be derived, tests for it have identified its presence in the tissues of animals

The first of these tests was devised by Leech and Bailey⁴ It detects alloxan in quantities as small as 0.05 mg in blood, and with slight modifications in certain tissues, including the pancreas It has been found that alloxan reaches its highest level at the end of injection, following which it rapidly decreases, with complete disappearance from the blood in five minutes It is found in the tissues of the pancreas in quantities of 24 to 56 mg per 100 gm at the end of the injection

A second test, devised by Banerjee, Dittmer and du Vigneaud,⁵ involves the conversion of alloxan into riboflavin, a phenomenon that is measured by microbiologic and fluorometric techniques It is useful only for the detection of alloxan in aqueous solu-

tions These authors confirmed the results of Leech and Bailey regarding the stability of alloxan at various hydrogen-ion concentrations They showed that alloxantin, which acts similarly to alloxan, yields the same amount of riboflavin as does alloxan Incidentally, the fact that alloxan and alloxantin are closely akin to a vitamin is interesting, even if not yet proved to be significant Moreover, if alloxan can be converted into riboflavin, the reverse may well be possible

Ruben and Tipson,⁶ in a preliminary paper, have recently reported the detection by another method of what they assumed to be alloxan in the normal livers of the steer, cat, calf, domestic fowl, guinea pig, lamb, rabbit and rat

Finally, Archibald⁷ has described six methods for the detection of alloxan under varying conditions As a result of his tests, he concludes that the blood plasma and urine of normal human beings and dogs must contain less than 0.02 mg of alloxan per 100 cc The addition of alloxan to filtrates of whole blood containing glutathione results in the formation of dialuric acid Archibald states that the possibility that circulating blood normally contains small amounts of alloxan should not be overlooked

These various tests for alloxan and the demonstration of its existence and reactions under varying conditions in animals count toward its conceivable importance in diabetes

Substances closely akin to alloxan act similarly to it The first of these is alloxantin, which was referred to in my last progress report³ Styryl quinoline No 90, which was originally found by Dunn to destroy the islet cells, has not as yet been proved to cause diabetes, but Bruchmann and Wertheimer⁸ have shown that methylalloxan, dimethylalloxantin, dialuric acid and methyl dialuric acid produce it in rats when injected intravenously The demonstration that these bodies, so closely related to alloxan, also cause diabetes suggests that if the search is continued, the actual chemical that plays the diabetogenic role can be found

Neutralized alloxan or alloxan dissolved in either rabbit or human blood plasma is not diabetogenic This discovery, of which I was aware a year ago, has now been published by Leech and Bailey⁴ Weinglass, Frame and Williams⁹ have gone a step farther and shown that 3-4, diamino-toluene, orthophenylene-diamine or sodium bisulfite, if injected intravenously within five minutes before alloxan is given,

*Clinical professor of medicine, emeritus, Harvard Medical School
medical director, George F Baker Clinic, New England Deaconess Hospital

prevents its diabetogenic action. A marked decrease in the blood glutathione invariably follows the injection of a diabetogenic dose of alloxan.¹⁰ When the molecular equivalent (400 mg per kilogram of body weight) of reduced glutathione is injected immediately before and during the injection of 200 mg of alloxan per kilogram of body weight, the glutathione fails to prevent the subsequent diabetes. The blood-alkoxan and blood-reduced-glutathione determinations made in 6 rabbits injected with 200 mg per kilogram suggest that there is an immediate reaction between alloxan and blood-reduced glutathione, with a tendency toward the complete disappearance of both. The critical level at which blood-reduced glutathione changes tend to parallel the development of diabetes is about 100 mg per kilogram. During the slow development of diabetes through repeated small doses of alloxan, the blood-reduced glutathione tends to be increased over normal, with a sudden drop to normal as diabetes ensues.⁴

The rapidity of the action of alloxan in causing destruction of the islets of Langerhans and producing diabetes is so unlike the speed of development of the disease in human beings that the demonstration by Bailey, Bailey and Leech¹⁰ that repeated doses over a long period also bring on the disease naturally appeals to a clinician. This rapid destruction of the islets by a single large dose of alloxan, however, was shown by Goldner¹¹ and Gomori and Goldner¹² when they temporarily ligated the blood supply to half the pancreas and injected alloxan. The temporary ligatures were released five minutes later, and histologic sections revealed the absence of changes in the islet cells in the part of the pancreas deprived of blood for this period of time, whereas in the remaining portion the usual necrosis of the islets was present.

Marked differences exist between alloxan diabetes and the diabetes caused by partial pancreatectomy and the injection of anterior-pituitary extract. In the former particularly, the disease can be prevented or even cured if hyperglycemia is avoided, this is distinctly not the case with alloxan diabetes. Differences in the pathologic picture have been emphasized by Duff¹ as follows:

The hydropic degeneration of the beta cells produced by partial pancreatectomy appears to be identical with that produced by anterior-pituitary extracts. This change is at first reversible and only later progresses to irreversible cell damage. In both instances hydropic degeneration is probably caused by the excessive functional demands associated with hyperglycemia. In alloxan diabetes, the beta cells of the islets show, from the beginning, degenerative changes that lead quickly to necrosis without the appearance of a stage in any way resembling hydropic degeneration. The necrosis is probably caused by the direct action of alloxan on the islet cells, and this injury is irreversible.

It should not be overlooked, however, that there are resemblances between alloxan diabetes and the

diabetes caused by partial pancreatectomy and anterior-pituitary extract. Thus, Bailey, Bailey and Leech¹⁰ found that in the diabetes produced in one to three weeks by the daily injection of small doses of alloxan (40 mg per kilogram of body weight), the pancreas underwent a series of changes quite different from those following a single massive injection. With the small doses a wide variety of changes in the beta cells was apparent. Some of them looked almost normal, whereas in others degeneration was the only evidence of injury, and still others showed hydropic degeneration. On the other hand, these authors also state, "This complex picture of normal cells, slightly injured cells, cells with hydropic degeneration, irreversibly damaged cells and a mitosis in a single islet is not clearly duplicated in any other form of experimental diabetes or in human patients," but I have always understood this statement to mean that in these animals a remarkably comprehensive picture in a single islet can be found for which one would need to search in several islets in the human being.

Hughes and Hughes¹³ injected rats subcutaneously with repeated small injections of alloxan. They found that the larger and presumably older beta cells of the pancreas succumbed to the toxic action of concentrations of alloxan that were too low to damage young beta cells.

Further studies on animals with slowly produced alloxan diabetes must be made and reported before one can reach a final conclusion that the histologic picture of alloxan diabetes is essentially different from that of the other two experimental forms of the disease. Kennedy and Lukens,¹⁴ as well as Bailey, Bailey and Leech,¹⁰ also noted hydropic degeneration in an animal with alloxan diabetes, but they attributed it to the effect of hyperglycemia on beta cells that had escaped destruction by the alloxan.

In this connection, the experience of Carrasco, described in my last report,³ is of interest. A dog that he injected with alloxan developed diabetes in a mild form but subsequently recovered. This result makes it clear that the pancreas of an alloxan-injected animal may regenerate just as does the pancreas in diabetes induced surgically or by anterior-pituitary extract. Furthermore, it should be borne in mind that in diabetes in human beings, hydropic degeneration has steadily grown rarer and rarer, with an accompanying decrease in the mortality from the disease in the first days, weeks and months following its onset. It is true that further experiments with alloxan are needed before it can be determined whether the fibrosis and hyalinization of the islands, so frequent in human diabetes, will appear when experimental conditions are set to allow an opportunity for it. Moreover, too little time has been spent by investigators of alloxan diabetes in studying the possibility of altering its course by diet, reduction of blood sugar and the

giving of insulin. Thus, Burn, Lewis and Kelsey¹⁵ demonstrated that rats with alloxan diabetes when placed on a high-fat diet showed a disappearance of the glycosuria, which remained absent until the normal diet had been resumed. An abrupt resumption of the high-fat diet was accompanied by some ketonuria, but on a gradual increase of the fat component the glycosuria disappeared without the development of ketonuria. In other words, alloxan diabetes in rats may at times be controlled by diet. After successive periods of a high-fat diet, the glycosuria seen on a return to a normal diet steadily diminished.

The regular appearance of diabetic cataracts in rabbits, and less frequently in rats, observed by Bailey, Bailey and Leech within two months after injections of alloxan, reminds one of the frequency of such a complication in human beings with diabetes. Such cataracts have been shown in partially depancreatized dogs and also in depancreatized rats,¹⁶ and I understand have been reported in the pituitary diabetes of a dog. The observations of the Boston group have been confirmed by Chesler and Tislowitz¹⁷ in rats, and personal communications state that cataracts have been found at various other laboratories, in Cleveland and Philadelphia.

Various birds, such as owls, ducks and chickens, have been intravenously injected with alloxan by Scott, Harris and Chen¹⁸ without developing diabetes. Pigeons, however, developed hyperglycemia and showed normal islets, but with occasional hydropic degeneration. Pigeons, like human beings, do not convert uric acid into allantoin, but they respond to alloxan in the same way as do animals that produce allantoin from uric acid. The same holds true for the Dalmatian hound. Goldner¹¹ noted the occurrence of a whitish deposit, identified as sodium urate, in the pericardium, pleura and liver of many diabetic pigeons with diabetes. This was not observed by Mirsky¹⁹ in his report of experiments with alloxan in ducks. Hyperglycemia was produced, but as in pigeons, there was only partial necrosis of the islands of Langerhans. Mirsky found necrosis without diabetes when 50 to 750 mg of alloxan per kilogram of body weight was injected into the wing vein of ducks. Two hundred milligrams caused death within three to forty-eight hours. Hyperglycemia occurred in some birds but not in others. Hypoglycemia was not noted. The islets of ducks appear to be sensitive to large doses of alloxan, but Mirsky states that these birds do not require intact islands to maintain carbohydrate metabolism and thus differ markedly from other species. One duck, following the injection of 50 mg of alloxan per kilogram, showed necrosis in nine days but no hyperglycemia.

Ramos²⁰ reports hyperglycemia with sugar values reaching 242 mg per 100 cc in turtles two days after the injection of alloxan. Goldner and Gomori²¹ pur-

sued their studies on carbohydrate in uric acid metabolism in pigeons following injections of alloxan. The blood sugar was increased from the normal daily level of 150 mg to 300 to 400 mg. Smaller doses caused a similar syndrome but without a rise in the blood sugar. The uric acid increased from the pre-*alloxan* level of 4.2 to 7.0 mg to 8 to 34 mg in six hours and from 9 to 135 mg in twenty-four hours. Such an increase has been clinically recognized in human beings as a symptom of visceral gout. It was accompanied by a conspicuous atrophy of the musculature.

The more one experiments with alloxan, the more bizarre are the results. Thus, Thorogood and Zimmermann²² found that dogs made diabetic with alloxan and subsequently depancreatized required only one third of the insulin needed prior to pancreatectomy. Direct ligation caused little or no drop in the need for insulin. They also found that depancreatized dogs developed acidosis much more easily than did those with alloxan diabetes, although the diabetes in the latter was apparently severer. They thought that there might be a second hormone, possibly residing in the alpha cells, that acted in opposition to insulin and tended to prevent acidosis and coma.

Monkeys develop diabetes and also acidosis following injections of alloxan. This is unusual, as is pointed out by Goldner and Gomori,²¹ because monkeys do not always develop severe diabetes following pancreatectomy. According to Orias,²³ rats with 95 per cent of the pancreas removed are more resistant to the diabetic action of alloxan than are normal controls, but with repeated subliminal doses at ten-day intervals they tend to develop diabetes more readily than do normal rats.

Alloxan when introduced into the alimentary tract of rats causes the same changes in the islets of the pancreas, according to Ruben and Yardumian,²⁴ as those that it produces when injected into the tissues or peritoneal cavity. When this method is employed with a dosage sufficient to produce diabetes, however, distinct hepatic and renal damage occur.

Assays of the pancreases of dogs with alloxan diabetes for insulin show about 0.5 unit per gram, in contrast to the pancreases of normal dogs, which contain 2 or 3 units per gram.²⁵ For a comprehensive report of the factors affecting the insulin content of the pancreas, one should consult Haist's article.

The hyperglycemia that early results in animals injected with alloxan has been ascribed to gluconeogenesis in the liver. It has been duplicated by the simultaneous injection of adrenalin and insulin into animals. It has been prevented by the injection of alloxan into functionally or anatomically adrenalectomized rabbits, according to Goldner and Gomori.²⁶ Houssay, Orias and Sara²⁷ found that hyperglycemia did not occur in hepatectomized dogs or toads. They observed it in adrenalectomized

animals and dogs with a previous section of the splanchnic nerves and in recently hypophysectomized toads

The hypoglycemia that follows hyperglycemia in animals with alloxan diabetes is not directly caused by alloxan, because it does not occur in depancreatized dogs or dogs already made diabetic with alloxan. Furthermore, the injection of alloxan into eviscerated cats is not followed by a reduction in blood sugar.²⁵ Hypoglycemia has been thought to be due to the liberation of alloxan from the necrosing degenerated beta cells, and Goldner and Gomori²⁶ state that whenever hypoglycemia develops, diabetes follows if the animal survives. From this conclusion Houssay et al dissent. In fact, their conclusions regarding the triphasic blood-sugar changes in animals with alloxan diabetes are as follows

(1) The liver is essential for the initial hyperglycemia produced by alloxan. Hyperglycemia is observed in adrenalectomized animals and those with section of the splanchnic nerves. It must be attributed principally to a direct action of alloxan on the liver. (2) The secondary hypoglycemia is not due to liberation of insulin, but to an extrapancreatic effect, probably lack of glucose production by the liver. The liver of the animal already in a diabetic condition is generally insensible to this action of alloxan. (3) The final hyperglycemia is mainly due to the destruction of the beta cells of the islets of Langerhans, and becomes permanent if the animal survives. (4) The liver plays an important role during the three phases of modification of blood sugar level.

Kirschbaum, Wells and Molander²⁹ conclude as follows from their experiments

An initial hyperglycemia did not appear in either adrenalectomized or hypophysectomized rats injected with alloxan. With the doses of alloxan used, hypoglycemic convulsions did not appear in any of 15 intact animals, whereas convulsions occurred within six hours in all of 14 adrenalectomized and in 9 of 10 hypophysectomized animals. In the absence of the adrenal medulla the reaction to alloxan was the same as in intact animals. Removal of the adrenal cortex (regenerated cortex following adrenal enucleation) resulted in the same reaction as total adrenalectomy.

Foglia, Oras and Sara³⁰ injected alloxan subcutaneously into rats and found a prolonged initial hyperglycemia lasting for three to five hours, which was followed by a marked hypoglycemia. In previously pancreatectomized rats, however, subsequent injection of alloxan failed to affect the blood-sugar level.

Thomas and Emerson³¹ showed that the pituitary glands of rabbits given intravenously 200 to 300 mg of alloxan per kilogram of body weight revealed degeneration of the basophils and in some cases areas of necrosis in the adrenal cortex. Rats receiving 400 mg per kilogram subcutaneously developed similar lesions. Janes and Friedgood³² demonstrated that rats made diabetic with alloxan showed marked reduction or disappearance of their diabetic symptoms following adrenalectomy. Thus, they respond to adrenalectomy in a manner similar to that shown by pancreatectomized animals.

Pregnant rats injected with alloxan developed diabetes, according to Friedgood and Miller.³³ The

alloxan passed through the placenta but did not cause diabetes in the offspring. No reason for this is given. Chesler and Tislowitz¹⁷ found that alloxan dwarfed the growth of immature rats. Lowry and Hegsted,³⁴ using rats on a thiamin-deficient diet, demonstrated that rats made diabetic with alloxan develop thiamin deficiency at approximately the same rate as normal controls, or perhaps slightly less quickly. Furthermore, the response of the diabetic animals to thiamin therapy was more marked than that of the controls. Schneider, Lewis, Moses and McCullagh³⁵ report diabetic retinitis associated with reduction of the plasma protein in rabbits made diabetic with alloxan. They describe changes in the lens in 15 rabbits.

With the aid of deuterium, Stetten and Boxer³⁶ found that on a diet that was 60 per cent carbohydrate one fourth of the urinary glucose formed by rats with alloxan diabetes was synthesized *in vivo* and the other three fourths was derived from the dietary carbohydrate. The proportion of liver glycogen synthesized from fragments smaller than hexose was greater than had been found in normal rats. Synthesis from fatty acids decreased to 5 per cent of the normal rate. This failure of the diabetic animal to utilize glucose in the synthesis of fatty acids constitutes a major metabolic defect in this disease.

Comparative studies of the action of alloxan on the islet cells of the pancreas and the convoluted tubules of the kidney in the rabbit, the dog and man have been published by Brunschwig and Allen.³⁷

Interest in alloxan diabetes continues unabated. Published work in 1945 emanated from at least twenty-five different laboratories in eight countries. With the cessation of the war, one may expect this year twice the number of reports published in 1945.

CARBOHYDRATE CHEMISTRY

Carbohydrate chemistry has made marked strides in the last few years. Perhaps one of the most spectacular discoveries has been the synthesis of glycogen *in vitro* by Cori.³⁸ Even more recent is the work of Hastings,³⁹ who has shown by the use of radioactive tracer elements that a substance seemingly as remote from carbohydrate as bicarbonate of soda can under suitable conditions take part in the creation of a carbohydrate molecule. The influence of insulin on blood pyruvate localized in a general way the action of insulin, but the crucial point in the breakdown of carbohydrate at which there is interference in its utilization, as in diabetes, has always been a mystery. Evidence that may furnish a valuable clue to the solution of the problem has recently been reported by Price, Cori and Colowick.⁴⁰ In the utilization of glucose by animal tissues this substance is ordinarily transformed to glycogen by oxidation, which is catalyzed by hexokinase (glucose and adenosine triphosphate glucose-6 phosphate and adenosine diphosphate). According to these au-

thors, anterior-pituitary extract inhibits this reaction, as shown either by injecting rats with it prior to the preparation of tissue extracts or by adding it to the enzyme preparation in vitro. Moreover, — and this is of vital importance, — this inhibition can be counteracted by insulin, either in vivo or in vitro.

Of particular interest is the statement of Price et al that rats made diabetic by the injection of alloxan yield tissue extracts that show the same enzyme activity curve as do those obtained from rats made diabetic by anterior-pituitary extract. The brain, they point out, is an apparent exception, since brain extracts prepared from rats injected with alloxan or with anterior-pituitary extract do not show an inhibition of hexokinase activity. Brain extracts can, however, be inactivated by addition of anterior-pituitary extract in vitro.

Anterior-pituitary extract does not inhibit the conversion of glycogen to lactic acid in muscle extract. In a dialyzed liver dispersion, when oxygen consumption is measured, oxidation of glucose is inhibited by anterior-pituitary extract, whereas that of fructose-6-phosphate and of pyruvate is not. Insulin releases hexokinase from inhibition by anterior-pituitary extract in all cases. It does not by itself enhance hexokinase activity under these experimental conditions. Price et al state

Within a certain range the release of inhibition is proportional to the amount of insulin added in vitro. That the in vivo action of insulin is of a similar nature is indicated by the fact that muscle extracts prepared from diabetic rats after the injection of insulin show normal hexokinase activity. When insulin is reduced by cysteine, it no longer exerts its antagonistic effect against anterior-pituitary extract inhibition of hexokinase activity.

The authors promise to discuss in later publications the implications of this important discovery.

DIABETIC NEUROPATHY

An outstanding summary of diabetic neuropathy, with the listing of 171 references, as well as a contribution to the subject, has recently been published by Rundles.⁴¹ Like the reviews by Duff² and Haist,²⁸ elsewhere cited, this work is to be held up as an example for future authors. All these articles deserve detailed comment, but the greater clinical importance of Rundles's paper forces me to give it preference.

Diabetic neuropathy has been described for over fifty years, and such names as Marchal de Calvi, Bouchard, Pavy, Leyden, Charcot and others less familiar have been associated with it. In 1936, Jordan⁴² published a comprehensive summary of the data on neuritis available at the George F. Baker Clinic at that time. Rundles's article has been excellently reported in an editorial in the *Journal of the American Medical Association*,⁴³ to which those who do not have access to the original paper may turn. Several points made by Rundles, based on his experience with 125 cases among some-

what more than 3000 new diabetic patients during a seven-year period, deserve emphasis. Of these he studied 35 personally. From his intensive survey of the literature and his own observations, he reached definite conclusions, which are most important for any physician treating a diabetic patient. He states "Most diabetics who develop organic disease of the peripheral nerves have had antecedent periods usually of months or years' duration of grossly neglected or poorly managed treatment. There is strong evidence that the disordered metabolism of diabetes mellitus itself is the etiologic factor in this as well as other accompanying diabetic complications." Rundles cites 5 cases of his series in detail. The first of these patients had typical symptoms of neuritis in the fingers and feet, following careless treatment for diabetes. In addition, she had discoloration of the right great toe and a blistered leg, which she attributed to a burn. The toe became dark purple, and pus exuded from it. After four weeks of hospitalization with orthodox treatment of the diabetes by an 1800-calorie diet containing 150 gm of carbohydrate and 80 gm of protein, and 10 units of insulin three times a day, the infected toe healed, although there was no definite alteration in the neurologic status.

The second case was that of a boy twenty years old with diabetes of six years' duration. In addition to characteristic symptoms of neuritis in the lower extremities and a so-called "low abdominal bulge," due to a quart of residual urine in the bladder, the patient showed the customary elevated spinal-fluid total protein (69 mg per 100 cc), first emphasized by Root.⁴⁴ Six weeks after admission, cloudy vision developed. An ophthalmology consultant, finding macular edema, punctate and flame-shaped hemorrhages and extensive areas of exudate, diagnosed severe diabetic retinopathy. Six weeks later there had developed an extensive proliferating retinopathy with both fundi filled with new-formed, dilated and tortuous veins and capillaries, with even more extensive deep and superficial hemorrhages but no further visual impairment. With diabetic control, supplemented by vitamins, the patient was discharged after four months little improved, but was seen at intervals for another eighteen months. The diabetes remained well controlled. He gradually gained in weight and strength, and the retinal hemorrhages became less extensive. To all physicians interested in diabetes the report of the condition of the eyes is significant. The consultant found the retinopathy much improved, reporting only minimal pigmentary disturbance in the regions of former hemorrhage, slight wrinkling and fibrotic scarring in different areas, a few new-formed blood vessels and a rare rosette-shaped hemorrhage. Rundles describes this result as the most astounding recovery of a diabetic retinitis of this type and severity he has ever seen or heard of. Unfortunately, such an experience is unique. Most ophthalmolo-

gists agree that diabetic neuropathy is almost always progressive and that retinitis proliferans rarely, if ever, improves.

The limits of space forbid the citation of the many interesting observations recorded by Rundles, but it must be pointed out that more than one fourth of his patients were less than forty years of age, with 8 of them twenty or younger. There was no predilection for welfare patients as compared with those of average or superior means, but all the patients showed lax diabetic care. No case was seen in which diabetic neuropathy actually preceded the appearance of diabetes mellitus. Furthermore, Rundles states that none of these patients were among those regularly attending his diabetic clinic or under the adequate supervision of competent physicians with provision for enlightened dietary management and checkup visits. These findings confirm the observations of Joslin and Root⁴⁵ that the symptoms of diabetic neuropathy always start during a time of uncontrolled diabetes.

Muscular cramps and aching in various parts of the body were early symptoms, and muscular weakness, especially of the legs, was almost uniformly present, 4 of the patients being able to go upstairs at home only by crawling on their hands and knees. Numbness, tingling and paresthesias, and shooting pains, characteristically worse on exposure to cold and at night, making the touch of bedclothes unbearable and sleep impossible, were frequent complaints. The lower extremities were most severely affected. The peroneal nerve was more vulnerable than the tibial, and the ulnar more vulnerable than the radial or median. Occasionally symptoms appeared in the pudendal, femoral or intercostal nerve areas or in asymmetrical areas in the extremities. The Achilles tendon reflexes were absent in 81 per cent of the cases, and patellar reflexes in 56 per cent, and each was diminished in an additional number of cases. Rundles considers diminished or absent tendon reflexes to be the most reliable single sign of diabetic peripheral nerve disease.

Gastrointestinal dysfunction, with diabetic, often nocturnal, diarrhea, and genitourinary and sphincter disturbances, are discussed. Rundles calls special attention to disease of the peripheral autonomic nerves, which was evidenced by damage to the peripheral sympathetic nerves and revealed by sweating, loss of vasomotor and pilomotor control and dependent edema. His knowledge in this regard was gained from the 35 patients whom he studied personally. Among these there were 26 patients who had dependent edema of the lower extremities appearing during the course of the neuropathy, which Rundles ascribed to involvement of the vasomotor nerves. Orthostatic hypotension and orthostatic tachycardia were observed and are also discussed. The association of diabetic neuropathy and retinopathy is emphasized, together with the fact that they may appear in the absence of hyper-

tension, impaired renal function and albuminuria. Wagener, Dry and Wilder⁴⁶ pointed out that retinal disease and peripheral-nerve disease were frequently associated in diabetic patients, and that 25 per cent of a large group of patients with diabetic retinitis had diabetic neuritis in addition. Rundles found that the converse relation, also held in his patients with diabetic neuropathy, since 43 (34 per cent) of the 125 patients had retinal disease characteristic of that due to diabetes. The coincidence of these two diabetic complications appears to him to be more than fortuitous. Acceptable evidence of occlusive arterial disease in patients with diabetic neuropathy was not unduly frequent. McKittrick and Root⁴⁷ have likewise noted the presence of neuritis in a considerable percentage of patients with lesions of the lower extremities in the absence or notable lack of vascular disease.

Deficiencies of vitamins were not observed, and the therapeutic use of vitamins, especially the vitamin B complex, was not found useful. This fact corroborates Jordan's⁴² detailed study of 63 patients, in only 1 of whom the diet appeared to have been deficient. Rundles further states that a number of recent patients who had been given no vitamin supplements appeared to be recovering from their neuropathy as rapidly as had any others in the past, and adds that he has never seen clinical improvement in diabetic neuropathy by any treatment regimen in the absence of effective diabetic control.

The diagnosis of diabetic neuropathy is one of the least precise, because it is easy to ignore the muscular weakness, aches and pains of acute diabetic non-regulation, particularly if the neurologic examination is inexpert. All that Rundles writes along these lines emphasizes the importance of an article by the late Dr Abraham Rudy,⁴⁸ in which he reports numerous cases of neuropathy in old-aged diabetic patients who were returned to well-being by the application of prolonged diabetic care and control of their disease.

The prognosis in diabetic neuropathy varies according to the severity of the neuritic disease. Recovery may take place within a few weeks or in six to twelve months, and in severe cases it may require one or two years.

In conclusion, Rundles points out the following

Occlusive arterial disease, diabetic cataracts, and advanced stages of diabetic retinopathy are late complications representing irreversible organic changes, which diabetic treatment will not alleviate and for which other treatment offers but poor compensation. Neuropathy, along with early stages of retinopathy and hepatomegaly, should be emphasized as reversible diabetic complications always a warning to both physician and patient of inadequately controlled diabetes which in the course of time, if uncorrected, will lead to widespread and permanent degenerative changes. At least 50 per cent of all diabetics will survive with little or no treatment for many years. In them the ultimate development of degenerative complications is the only criterion by which the adequacy of their treatment can be judged.

This article by Rundles is one of the most important in recent years, since it proves the necessity for painstaking and aggressive treatment of diabetes from its incipency to its very end

(To be concluded)

CASE 32131

PRESENTATION OF CASE

A sixty-nine-year-old housewife entered the hospital in collapse

On the morning of admission she had an attack of excruciating substernal and epigastric pain and collapse lasting nearly an hour and followed by a loose bowel movement Three hours later, in the early afternoon, she was well enough to attempt to stoke the household furnace While at this task she had a second attack of upper abdominal pain, severer than the first The pain radiated to the left shoulder She apparently collapsed and was found lying on the floor about five hours later and was brought to the hospital

About five years before admission the patient had had an episode of deep right chest pain radiating to the scapula This attack was said to have been initiated by exercise and relieved by rest In the following years she had had attacks of epigastric pain approximately every six months, it began as a squeezing, nonradiating pain followed by nausea, vomiting and syncope for one to three hours There were no intervening symptoms She had known that she had hypertension for an indefinite number of years There had been no exertional dyspnea or ankle edema Many years previously she had had an ovary and a "tumor" removed from the abdomen

On physical examination the patient was cyanotic and responded poorly The apical impulse was not visible, and the left border of cardiac dullness was poorly defined, although it appeared to be just outside the midclavicular line The heart sounds were distant and at times were not heard There was moderate dullness over the left chest posteriorly from the spine to the posterior axillary line Breath sounds were diminished over this area There was severe epigastric tenderness without spasm No abdominal masses were palpated There was an old longitudinal midline scar above the symphysis Rectal examination was negative

The temperature was 97°F, the pulse 98, and the respirations 25 The blood pressure was unobtainable

The red-cell count was 4,020,000, with a hemoglobin of 8.5 gm, and the white-cell count 14,100 The urine had a specific gravity of 1.020, and the sediment contained 1 or 2 red cells and 15 to 20 white cells per high-power field A glove specimen of stool was guaiac negative The serum amylase was 29 units, and the nonprotein nitrogen 26 mg per 100 cc A portable x-ray film of the chest showed poor visualization of the left half of the diaphragm The heart was enlarged, and there was marked enlargement of the aorta

On the morning after admission the patient was more alert and her abdominal pain had lessened She had developed a severe productive cough, and the white-cell count rose to 25,900 There was no change in the temperature or pulse With plasma and saline the blood pressure rose to 80 systolic, 60 diastolic At 7.50 p.m. the same day she had a sudden severe pain under the right scapula and in the right axilla The blood pressure fell slightly but soon rose to 120 systolic, 70 diastolic At 8.20 p.m. she had another attack of excruciating pain in the same region and suddenly died

DIFFERENTIAL DIAGNOSIS

DR ALLAN G BRAILEY It seems to me that this woman died of cardiovascular disease One might think in passing of acute pancreatitis, but when she came to the hospital the serum amylase was found to be normal and the subsequent course seems completely inconsistent with pancreatitis Pulmonary embolism deserves attention The pain of embolism, however, is not so agonizing as that described here Embolism of such degree as to cause collapse would produce marked dyspnea, and there is no mention of evidence of dilatation of the right heart, such as distended neck veins There is no hint of a likely source of emboli, although the source is frequently obscure There is no mention of bloody sputum I do not believe that we need to suppose she had embolism as a primary cause of death

The two diagnoses that have to be carefully juxtaposed are myocardial infarction and dissecting aneurysm The story is consistent with infarction The patient was sixty-nine years old and was therefore likelier to die of coronary disease than of dissecting aneurysm Five years previously she had had chest pain brought on by effort and which may have been evidence of pre-existing coronary disease The heart signs and blood pressure are apt to be well maintained in dissecting aneurysm This patient, however, was obviously in shock when she came in, and the poor quality of the heart sounds and blood pressure could be as logically ascribed to shock as to the underlying condition The location of the pain was substernal and upper abdominal Three hours later the second attack was said to have been epigastric It is a good story for myocardial infarction but pain proceeding downward constitutes one argument in favor of dissecting

aneurysm There was no pericardial friction rub Of course that frequently is not present even with massive cardiac infarction An electrocardiogram would be a great help Was one taken?

DR TRACY B MALLORY No

DR BRAILEY It seems unlikely that a person three hours after severe infarction would feel like getting up and stoking a furnace

DR ROBERT L BERG A cardioscope was taken in the Emergency Ward and was negative

DR BRAILEY The fact that she made a temporary recovery to the point where she was willing to stoke the furnace suggests that her attack was due to dissecting aneurysm She was known to have hypertension for years, a constant prerequisite for dissection The character of the onset of the pain in these cases is usually significant, but we cannot be too sure what it was like here If it came on suddenly, it would favor aneurysm The pain of cardiac infarction comes on over a period of a few minutes If she had a dissecting aneurysm, the terminal episode of pain in the right chest might have resulted from dissection upward Four seizures of terrific pain in twenty-four hours favor an aneurysm with discontinuous dissection It is not likely that she had four such closely repeated infarctions of the heart Somewhat against dissection is the report that the blood pressure stayed low If it did stay low, we have to assume that this was due to a state of shock It may be significant that the last two attacks of pain occurred only after the blood pressure began to rise A more serious objection is the fact that no evidence is given of occlusion of the branches of the aorta, but some of the intercostal branches might have been occluded without producing obvious symptoms in so sick a patient

Are there any x-ray films?

DR MILFORD D. SCHULZ The film has been lost

DR BRAILEY I should like to know particularly about the aorta If it was enlarged it might easily have resulted from hypertension and arteriosclerosis I also wish I knew how big the right ventricle was Nothing is said about that

The patient died suddenly How sudden is "suddenly"? Instantaneous death from heart disease may be due to ventricular fibrillation, to cardiac standstill or to rupture of the heart or aorta, but she certainly had not had coronary occlusion long enough to have ruptured the heart She could easily have died of a disturbance of rhythm This is a difficult problem to decide, but I shall vote in favor of dissecting aneurysm and try to justify it on the basis that the pain moved downward, that she had four attacks of terrific pain of sudden onset and that death was instantaneous

DR MALLORY Dr Berg, will you tell us how the discussion ran on the wards?

DR BERG When she first came in she was seen in the Emergency Ward and was in coma No history was obtainable She was given intravenous

fluids and became somewhat responsive She had abdominal pain and was extremely tender in the epigastrium The chief problem was whether her condition represented an intra-abdominal catastrophe or something originating in the cardiovascular system The surgeons saw her at that time and agreed that there was no immediate need of surgical intervention, and as she improved we were able to get the rest of the story, which focused more closely on the cardiovascular system as time went on I personally did not see the x-ray film, but Dr John Stanbury, who admitted the patient, said that it showed a very much enlarged aorta She was sent up to the wards with a diagnosis of dissecting aneurysm

So far as the manner of death is concerned, I might add that after the last attack of pain she died within thirty seconds

DR CHARLES H BURNETT There was no question from the x-ray film that the aorta was markedly enlarged

DR MALLORY Does that alter your opinion, Dr Brailey?

DR BRAILEY No, it rather helps to confirm my diagnosis

DR ALBERT J STUNKARD The blood pressure, which was unobtainable in the Emergency Ward, was up the next morning

CLINICAL DIAGNOSES

Dissecting aortic aneurysm
Arteriosclerotic heart disease
Bronchopneumonia

DR BRAILEY'S DIAGNOSES

Dissecting aneurysm of aorta

ANATOMICAL DIAGNOSES

Ruptured syphilitic aneurysm of aorta
Hematoma of mediastinum

PATHOLOGICAL DISCUSSION

DR MALLORY This patient showed a large fusiform aneurysm of the thoracic aorta, not a dissecting aneurysm, but I believe a syphilitic one, despite her advanced age Patients with syphilitic aneurysm do not ordinarily reach the age of sixty-nine The specimen grossly was strongly suggestive of syphilis, it showed wrinkling, so-called "tree barking" and stellate scarring of the intima Microscopically there were many foci of destruction in the media and also a marked perivascular cuffing with lymphocytes and occasional plasma cells, characteristic of syphilitic aortitis The aneurysm had ruptured, and a massive hematoma of the mediastinum had formed There was then dissection of this hematoma in various directions—upward to the base of the heart and downward into the serosa of the stomach, a large portion of which was lifted off the muscularis by the clotted blood

It is quite probable that the epigastric pain and tenderness were directly related to this last extension of blood. It had broken into one pleural cavity, where about 900 cc of fluid was found, about half of it consisting of blood clots.

It was not a true dissecting aneurysm because, as you know, in a dissecting aneurysm the separation in the aorta is within the media so that muscle fibers of the media are found on each side of the plane of dissection. Under such circumstances the pressure in the newly dissected vessel equals or exceeds that within the main aortic lumen, thus occluding by external pressure the small aortic branches. Dr Brailey looked for clinical evidence of this phenomenon in the record but could not find it.

CASE 32132

PRESENTATION OF CASE

A seventy-year-old physician entered the hospital because of persistent vomiting.

Six months before admission the patient began to complain of epigastric fullness and indigestion. He restricted his diet to fluids and soft foods and in six months lost 20 pounds. Ten days prior to admission he had an attack of vomiting, with epigastric discomfort, the vomitus was foul smelling. He was constipated, and enema returns were slight.

On physical examination there was a soft nontender mass in the left upper quadrant that extended from the rib margin to the level of the umbilicus and moved slightly with respiration. There was slight clubbing of the fingers.

The temperature was 98°F, the pulse 90, and the respirations 18. The blood pressure was 140 systolic, 90 diastolic.

The red-cell count was 4,300,000, and the white-cell count 12,200, with 75 per cent neutrophils. The urine had a specific gravity of 1.012, there was no albumin. The prothrombin time was 20 seconds (normal, 14 to 16 seconds), the nonprotein nitrogen 27 mg per 100 cc, the serum protein 6.1 gm, and the chloride 106 milliequiv per liter.

An x-ray film of the chest showed bright lung fields. Between unusually prominent pulmonary markings there were dispersed numerous rounded translucent areas. The appearance was consistent with pulmonary fibrosis with some cystic changes. An intravenous pyelogram revealed a tumor mass filling the left flank and kidney area, its outline was indefinite. There was no filling of the left kidney pelvis. The right kidney functioned normally. In a retrograde pyelogram, the left ureter filled throughout. It was small and swung to the right so that it crossed the spine at the fifth lumbar vertebra. The pelvis was flattened, rotated and lay almost to the right of the spine.

A gastrointestinal series taken on the eleventh hospital day showed that the stomach, colon and duodenum were deformed by an apparently ex-

trinsic mass on the left side. The stomach was displaced upward and anteriorly. The duodenal bulb was compressed toward the right. The ligament of Treitz was pressed forward and downward. The descending colon was displaced laterally, and the splenic flexure upward. There was barium in the stomach, terminal ileum and cecum twenty-four hours after the meal.

The patient had a slight fever on the thirteenth day, and there was tenderness in the left costo-vertebral region. These signs quickly disappeared. Another urine showed 10 to 15 white cells per high-power field, and on culture there was a moderate growth of *Staphylococcus albus*.

An operation was performed on the twenty-second hospital day.

DIFFERENTIAL DIAGNOSIS

DR FLETCHER H COLBY: Since the diagnosis rests largely on the x-ray findings, I shall ask the roentgenologist to interpret the films now.

DR JAMES R LINGLEY: The chest shows a diffuse linear density throughout both lungs that is consistent with fibrosis. The hilar shadows are prominent and perhaps somewhat nodular. Incidentally, in cases of this type one should always think of diffuse pulmonary metastases. The plain abdominal film shows density throughout the left side of the abdomen, apparently due to a large mass the margins of which are not too well defined. On the retrograde film, there is displacement of the ureters to the right and the kidney pelvis is not well filled. In the intravenous pyelogram there is no evidence of excretion on the affected side. The gastrointestinal films show displacement of the stomach to the right and some displacement of the descending colon.

DR COLBY: Is the pulmonary picture consistent with metastases?

DR LINGLEY: I think it is more consistent with fibrosis, but metastatic disease is a possibility.

DR COLBY: The x-ray report states that the renal pelvis on the affected side was flattened and rotated. That is an important finding, but I suggest that the irregularity in this region represents ureter and not renal pelvis.

DR LINGLEY: I believe that you are correct. The pelvis is probably not filled on the affected side.

DR COLBY: Are these x-ray findings in the gastrointestinal tract — the displacement of the stomach, duodenum and large bowel — quite consistent with a tumor arising from the right kidney?

DR LINGLEY: I believe that the mass is a greatly enlarged left kidney.

DR COLBY: We have a patient seventy years of age who had had gastrointestinal symptoms for at least six months. He had had persistent vomiting for the ten days before entry. On examination there was found a large mass that filled the left loin and extended down almost to the pelvis on that side. From the x-ray study with pyelograms, intravenous

aneurysm There was no pericardial friction rub Of course that frequently is not present even with massive cardiac infarction An electrocardiogram would be a great help Was one taken?

DR TRACY B MALLORY No

DR BRAILEY It seems unlikely that a person three hours after severe infarction would feel like getting up and stoking a furnace

DR ROBERT L BERG A cardioscope was taken in the Emergency Ward and was negative

DR BRAILEY The fact that she made a temporary recovery to the point where she was willing to stoke the furnace suggests that her attack was due to dissecting aneurysm She was known to have hypertension for years, a constant prerequisite for dissection The character of the onset of the pain in these cases is usually significant, but we cannot be too sure what it was like here If it came on suddenly, it would favor aneurysm The pain of cardiac infarction comes on over a period of a few minutes If she had a dissecting aneurysm, the terminal episode of pain in the right chest might have resulted from dissection upward Four seizures of terrific pain in twenty-four hours favor an aneurysm with discontinuous dissection It is not likely that she had four such closely repeated infarctions of the heart Somewhat against dissection is the report that the blood pressure stayed low If it did stay low, we have to assume that this was due to a state of shock It may be significant that the last two attacks of pain occurred only after the blood pressure began to rise A more serious objection is the fact that no evidence is given of occlusion of the branches of the aorta, but some of the intercostal branches might have been occluded without producing obvious symptoms in so sick a patient

Are there any x-ray films?

DR MILFORD D SCHULZ The film has been lost

DR BRAILEY I should like to know particularly about the aorta If it was enlarged it might easily have resulted from hypertension and arteriosclerosis I also wish I knew how big the right ventricle was Nothing is said about that

The patient died suddenly How sudden is "suddenly"? Instantaneous death from heart disease may be due to ventricular fibrillation, to cardiac standstill or to rupture of the heart or aorta, but she certainly had not had coronary occlusion long enough to have ruptured the heart She could easily have died of a disturbance of rhythm This is a difficult problem to decide, but I shall vote in favor of dissecting aneurysm and try to justify it on the basis that the pain moved downward, that she had four attacks of terrific pain of sudden onset and that death was instantaneous

DR MALLORY Dr Berg, will you tell us how the discussion ran on the wards?

DR BERG When she first came in she was seen in the Emergency Ward and was in coma No history was obtainable She was given intravenous

fluids and became somewhat responsive She had abdominal pain and was extremely tender in the epigastrium The chief problem was whether her condition represented an intra-abdominal catastrophe or something originating in the cardiovascular system The surgeons saw her at that time and agreed that there was no immediate need of surgical intervention, and as she improved we were able to get the rest of the story, which focused more closely on the cardiovascular system as time went on I personally did not see the x-ray film, but Dr John Stanbury, who admitted the patient, said that it showed a very much enlarged aorta She was sent up to the wards with a diagnosis of dissecting aneurysm

So far as the manner of death is concerned, I might add that after the last attack of pain she died within thirty seconds

DR CHARLES H BURNETT There was no question from the x-ray film that the aorta was markedly enlarged

DR MALLORY Does that alter your opinion, Dr Brailey?

DR BRAILEY No, it rather helps to confirm my diagnosis

DR ALBERT J STUNKARD The blood pressure, which was unobtainable in the Emergency Ward, was up the next morning

CLINICAL DIAGNOSES

Dissecting aortic aneurysm
Arteriosclerotic heart disease
Bronchopneumonia

DR BRAILEY'S DIAGNOSES

Dissecting aneurysm of aorta

ANATOMICAL DIAGNOSES

Ruptured syphilitic aneurysm of aorta
Hematoma of mediastinum

PATHOLOGICAL DISCUSSION

DR MALLORY This patient showed a large fusiform aneurysm of the thoracic aorta, not a dissecting aneurysm, but I believe a syphilitic one, despite her advanced age Patients with syphilitic aneurysm do not ordinarily reach the age of sixty-nine The specimen grossly was strongly suggestive of syphilis, it showed wrinkling, so-called "tree barking" and stellate scarring of the intima Microscopically there were many foci of destruction in the media and also a marked perivascular cuffing with lymphocytes and occasional plasma cells, characteristic of syphilitic aortitis The aneurysm had ruptured, and a massive hematoma of the mediastinum had formed There was then dissection of this hematoma in various directions—upward to the base of the heart and downward into the serosa of the stomach, a large portion of which was lifted off the muscularis by the clotted blood

It is quite probable that the epigastric pain and tenderness were directly related to this last extension of blood. It had broken into one pleural cavity, where about 900 cc of fluid was found, about half of it consisting of blood clots.

It was not a true dissecting aneurysm because, as you know, in a dissecting aneurysm the separation in the aorta is within the media so that muscle fibers of the media are found on each side of the plane of dissection. Under such circumstances the pressure in the newly dissected vessel equals or exceeds that within the main aortic lumen, thus occluding by external pressure the small aortic branches. Dr Brailey looked for clinical evidence of this phenomenon in the record but could not find it.

CASE 32132

PRESENTATION OF CASE

A seventy-year-old physician entered the hospital because of persistent vomiting.

Six months before admission the patient began to complain of epigastric fullness and indigestion. He restricted his diet to fluids and soft foods and in six months lost 20 pounds. Ten days prior to admission he had an attack of vomiting, with epigastric discomfort, the vomitus was foul smelling. He was constipated, and enema returns were slight.

On physical examination there was a soft non-tender mass in the left upper quadrant that extended from the rib margin to the level of the umbilicus and moved slightly with respiration. There was slight clubbing of the fingers.

The temperature was 98°F, the pulse 90, and the respirations 18. The blood pressure was 140 systolic, 90 diastolic.

The red-cell count was 4,300,000, and the white-cell count 12,200, with 75 per cent neutrophils. The urine had a specific gravity of 1.012, there was no albumin. The prothrombin time was 20 seconds (normal, 14 to 16 seconds), the nonprotein nitrogen 27 mg per 100 cc, the serum protein 6.1 gm, and the chloride 106 milliequiv per liter.

An x-ray film of the chest showed bright lung fields. Between unusually prominent pulmonary markings there were dispersed numerous rounded translucent areas. The appearance was consistent with pulmonary fibrosis with some cystic changes. An intravenous pyelogram revealed a tumor mass filling the left flank and kidney area, its outline was indefinite. There was no filling of the left kidney pelvis. The right kidney functioned normally. In a retrograde pyelogram, the left ureter filled throughout. It was small and swung to the right so that it crossed the spine at the fifth lumbar vertebra. The pelvis was flattened, rotated and lay almost to the right of the spine.

A gastrointestinal series taken on the eleventh hospital day showed that the stomach, colon and duodenum were deformed by an apparently ex-

trinsic mass on the left side. The stomach was displaced upward and anteriorly. The duodenal bulb was compressed toward the right. The ligament of Treitz was pressed forward and downward. The descending colon was displaced laterally, and the splenic flexure upward. There was barium in the stomach, terminal ileum and cecum twenty-four hours after the meal.

The patient had a slight fever on the thirteenth day, and there was tenderness in the left costo-vertebral region. These signs quickly disappeared. Another urine showed 10 to 15 white cells per high-power field, and on culture there was a moderate growth of *Staphylococcus albus*.

An operation was performed on the twenty-second hospital day.

DIFFERENTIAL DIAGNOSIS

DR FLETCHER H COLBY: Since the diagnosis rests largely on the x-ray findings, I shall ask the roentgenologist to interpret the films now.

DR JAMES R LINGLEY: The chest shows a diffuse linear density throughout both lungs that is consistent with fibrosis. The hilar shadows are prominent and perhaps somewhat nodular. Incidentally, in cases of this type one should always think of diffuse pulmonary metastases. The plain abdominal film shows density throughout the left side of the abdomen, apparently due to a large mass the margins of which are not too well defined. On the retrograde film, there is displacement of the ureters to the right and the kidney pelvis is not well filled. In the intravenous pyelogram there is no evidence of excretion on the affected side. The gastrointestinal films show displacement of the stomach to the right and some displacement of the descending colon.

DR COLBY: Is the pulmonary picture consistent with metastases?

DR LINGLEY: I think it is more consistent with fibrosis, but metastatic disease is a possibility.

DR COLBY: The x-ray report states that the renal pelvis on the affected side was flattened and rotated. That is an important finding, but I suggest that the irregularity in this region represents ureter and not renal pelvis.

DR LINGLEY: I believe that you are correct. The pelvis is probably not filled on the affected side.

DR COLBY: Are these x-ray findings in the gastrointestinal tract — the displacement of the stomach, duodenum and large bowel — quite consistent with a tumor arising from the right kidney?

DR LINGLEY: I believe that the mass is a greatly enlarged left kidney.

DR COLBY: We have a patient seventy years of age who had had gastrointestinal symptoms for at least six months. He had had persistent vomiting for the ten days before entry. On examination there was found a large mass that filled the left loin and extended down almost to the pelvis on that side. From the x-ray study with pyelograms, intravenous

and retrograde, I think it is fair to say that the mass was definitely localized in the left kidney and was presumably a tumor mass arising from that organ. It is not at all unusual to have gastrointestinal symptoms predominant from renal disease, although they are usually caused by right-sided lesions. These symptoms are regarded as being due either to involvement of the sympathetic nerves that supply the gastrointestinal tract, such as occurs in malignant disease, or to pressure of the enlarged kidney on the adjacent organs. The foul vomitus, the pressure defects on the stomach and duodenum, the displacement of the large bowel and the retention of barium lead one to think that the gastrointestinal symptoms were simply due to pressure from the large left-sided renal mass, particularly since no intrinsic lesion of the gastrointestinal tract was demonstrated.

The essential problem is to determine the nature of the left-sided renal mass. The possibilities to consider are a solid tumor arising from the renal parenchyma, a tumor of the renal pelvis with retention within the kidney, a large solitary cyst of the kidney and hydronephrosis.

So far as a solid tumor is concerned, there are several points that seem to be against it. In the first place, there was lack of bleeding. A single urine examination is recorded, but there were only a few white cells and no red cells. Solid tumors of the kidney, however, can go a long time without either gross or microscopic bleeding. Also against a solid tumor is the fact that the mass was described as being soft. Tumors of the renal parenchyma are firm and hard. The surgeon is frequently uncertain whether a mass involving a kidney is solid or cystic until operation. It seems unlikely, however, that this was a solid tumor. To me the x-ray findings are not characteristic of metastatic disease in the lung.

Tumors of the renal pelvis bleed early and often. This was not the case in this patient.

A solitary cyst of the kidney is a distinct possibility, but we have no definite information that would lead us to believe that this was a solitary cyst. In a solitary cyst there is usually a distinct rounded filling defect of the renal pelvis, which is extremely suggestive and sometimes quite characteristic. We lack that evidence here.

Hydronephrosis seems to be the likeliest cause of this large soft mass. The patient had had no pain,

but this can be explained by the slow development of the hydronephrosis. There had been no pain suggestive of calculus, and there is no shadow of stone by x-ray. There is, of course, a possibility of a non-opaque stone, but the fact that the patient had had no attacks of pain in the past is somewhat against this. The most probable cause of the hydronephrosis seems to be obstruction at the ureteropelvic junction, although the actual lesion is frequently not demonstrable at the time of operation.

DR TRACY B. MALLORY: Are there any suggestions or questions?

DR W. WILSON SCHIER: Could a retroperitoneal lipoma fit this picture?

DR COLBY: I have had little experience with retroperitoneal lipomas.

DR MALLORY: Dr Smith, will you tell us about your operative findings?

DR GEORGE G. SMITH: This patient had a large hydronephrosis, which extended well across the midline and seemed to push directly against the lower part of the stomach. There was nothing particularly remarkable about it. I do not remember whether the obstruction was at the ureteropelvic junction.

DR MALLORY: The operative note mentions a double pedicle. Would that suggest that aberrant vessels might have been the cause of the hydronephrosis?

DR SMITH: It might, but I do not know.

CLINICAL DIAGNOSIS

Cyst of left kidney

DR COLBY'S DIAGNOSIS

Hydronephrosis left kidney

ANATOMICAL DIAGNOSIS

Hydronephrosis left kidney.

PATHOLOGICAL DISCUSSION

DR MALLORY: What this hydronephrosis had to do with the patient's major symptoms, which were gastrointestinal, remains a problem. From the postoperative record it is evident that he was not relieved of the gastrointestinal symptoms by the removal of the kidney. Repeated x-ray examinations showed persistent gastric stasis, and eventually the stomach was explored by Dr L. S. McKittrick. He was unable to find any organic obstruction but nevertheless did a pyloroplasty, with some degree of relief.

MERGER AND MEDICAL SERVICE

THERE has been considerable interest and excitement in recent months about the proposed merger of the armed forces in this country. The obvious advantages from the point of view of efficiency and the importance of co-ordinated effort by all branches of the armed forces in modern warfare have been widely discussed. The resistance to such a merger by those who suspect that their branch might become subordinated in the course of such a merger is, of course, understandable. Nevertheless, the Secretary of the Navy has recently announced that plans are being drawn up and action is already being taken for the merging of several types of facilities that are now duplicated in the Army and Navy. This

is the first departure during peacetime from the traditional and not always good-natured rivalry between the different branches of the service. Arrangements are already being made for merging or co-ordinating activities of Army and Navy facilities in matters concerning procurement, intelligence, ports and shipping, air transport services and even recruiting and training.

No specific mention was made in this announcement about the merging of the medical departments of the services, but that is obviously an important function that could easily benefit by some sort of co-ordination and, probably better still, by complete unification. Although it may sound quite radical, it might not even be amiss to consider the possibility of removing the medical services entirely from the armed forces during peacetime, running them in conjunction with existing civilian institutions.

A good deal has appeared both in the medical and in the lay press about the superior quality of the medical services that were rendered to the armed forces during the war. The low case-fatality rates and the improved cure rates, as compared with those obtained in similar conditions during the last war, are always quoted as proof of this contention. Much of this improvement in end results, however, can readily be ascribed to technics and to life-saving therapeutic measures that had been evolved after the end of World War I but before the beginning of this war. In spite of this, there are still discrepancies between civilian and military practice that leave much to be desired.

One naturally expects the medical services of the armed forces to provide the best and most modern forms of treatment and care. Whether the actual accomplishments during this war are uniformly of as high a quality as one has been led to believe is open to question. Obviously open criticism of the services by officers while they are on active duty is well nigh impossible. In private, however, many of them have been quite vocal in their condemnation of many features of these services. It is to be hoped that, now that the war is over, their criticisms can be aired, and that the causes of any justifiable complaints can be ferreted out and corrected. Many physicians of high professional caliber have seen active service in all branches of the armed forces

Some of them were fortunate, having had the opportunity to utilize their skills to the fullest. Others of equal attainment spent most of their time in "paper work," while holding rather exalted ranks, and still others were treated much as enlisted men, being ordered to do menial duties without any reference to their skills and training. When these officers return to a civilian status, they may prefer to forget their gripes and to get back to their jobs, but they can render an important service by presenting and analyzing their observations and criticisms, unhampered by service regulations.

There are undoubtedly many features of medical service that could be improved as a result of the merging of the medical branches of the armed forces. A uniform and, it is hoped, better policy concerning appointments and assignments to duties based on experience and skill could well be instituted. The services and advice of leading medical authorities could then be better utilized than they have been in the past. A co-ordination of hospital and other facilities for the best management of all types of medical problems, as well as for research, would also accrue to the benefit of all the services. In setting up a new medical department, provision could be made for co-ordinating its activities with those of established medical centers, particularly, although not exclusively, those connected with teaching hospitals and medical schools, much in the same manner as is now being contemplated for the Veterans Administration. Inspiration derived from medical teachers, from those actively engaged in research and perhaps even from collaboration in research activities would help maintain the morale of the medical officers who elect to remain in service.

ALBRECHT VON HALLER — PHYSICIAN-EXTRAORDINARY

ALBRECHT VON HALLER was born at Berne, Switzerland, on October 16, 1708. It is reported that when he was ten years of age he could speak Latin, Greek, Hebrew and Chaldaic, having written verses in Latin, dictionaries for the Greek and Hebrew and a grammar for Chaldean. He studied medicine at Tübingen under Cavernarius and then at Leyden

under Boerhaave and Albinus, receiving his medical degree at nineteen, after submitting a thesis that proved that the so-called "salivary duct" claimed as a discovery by Coschwitz was a simple blood vessel.

He traveled for two years, visiting the University of Paris and the University of London, and then returned to Switzerland to study botany at Basle. He began a collection of plants that became the basis of his tremendous work on plant classification and Swiss flora published in 1742. In his spare time he wrote stories and verses. One of his poems, "*Die Alpen*," is still found in the anthologies.

Von Haller then returned to Berne, where for seven years he engaged in general practice. He applied for the post of city physician but was rejected with the comment "He is a poet. Why should he want to be a hospital physician?"

At the age of twenty-eight, his growing fame as a botanist and an anatomist led to his appointment by George II to the chair in botany, anatomy, surgery and medicine at the newly founded University of Göttingen, and during the next seventeen years he demonstrated a productivity of scientific research and study that has probably never been equaled. He lectured on the subjects covered in his appointment and in addition wrote a history of medicine, the first textbook of physiology, an atlas of angiology, one on pathology and the volume on the classification of plants previously mentioned. In original research he proved that muscle irritability was independent of nerve supply, that bile was concerned with fat digestion, that the pleural cavities contained no air, and that the heart beat was automatic in origin. He described the development of the embryo and the anatomy of the organs of generation and of the brain. In addition, he accurately explained the mechanism of respiration.

Von Haller founded the *Göttingische gelehrte Anzeigen*, a monthly journal, to which he contributed the almost unbelievable total of twelve thousand papers on almost every branch of knowledge. He continued to write verse and published several historical novels. It is difficult to envisage the circumstances under which this work was done, since it should be remembered that the time was the early

eighteenth century, thirty years before the Revolutionary War

In 1753, at the age of forty-five, he returned to Berne, where in the next twenty-five years he occupied several municipal and state offices. He prepared his *Bibliotheca medica*, of which he completed the botanical, anatomical, surgical and medical portions, a work that fills ten quarto volumes. He re-wrote his elements of physiology in four quarto volumes. He continued his nonmedical writing and published a history of Alfred the Great and two other philosophical romances, *Usonia* (1771) and *Fabius und Cato* (1774). He continued his classical studies by writing commentaries on Greek and Latin texts. With all this, until his death in 1777, he found time and energy to carry on a voluminous correspondence with the great scientists of his day.

Although the most famous surgeon of his time he would not operate on human beings. So great was his fame that some pirates who captured an English ship and found on it a package of books directed to him, considered it a crime to rob so learned a man and hurried to the nearest port in order that the books might reach him as soon as possible.

Von Haller was undoubtedly one of the most extraordinary men to grace the profession of medicine, yet he receives scant recognition in modern medical textbooks. Many anatomies do not associate his name with one of his important discoveries, — the vas aberrans, — and the majority of textbooks on physiology do not refer to him at all.

MASSACHUSETTS MEDICAL SOCIETY

SPECIAL MEETING OF THE COUNCIL

A special meeting of the Council of the Massachusetts Medical Society will be held in Boston on Wednesday, April 10, 1946, at 10:30 a.m., in Building E, Harvard Medical School, Longwood Avenue.

Business
1 Report of the Committee Appointed to Confer With Major General Hawley, Medical Administrator of the Veterans Administration, concerning the medical care of veterans by civilian physicians.

2 Schedule to cover fees for services under this heading.

MICHAEL A. TIGHE, M.D., Secretary

Building E is the first building on the right when the quadrangle of the Medical School is entered from Longwood Avenue.
Councilors are asked to sign one of the attendance books before the meeting. The Cotting luncheon will be served at 1:00 p.m. in the Dining Room of Vanderbilt Hall.

SECRETARY'S OFFICE

SURPLUS PROPERTY FOR VETERAN MEDICAL OFFICERS

Few discharged medical officers appreciate the fact that they are entitled to a priority in the purchase of surplus medical equipment, when, as and if it is available, and the majority of those who are aware of this fact have no idea concerning what steps to take in purchasing such equipment.

All who intend to apply must first obtain certification from one of the district offices of the War Assets Corporation. Four such offices are located in Massachusetts, as follows:

<i>Boston</i>	<i>Lowell</i>
Henry Boltz, district manager	E. J. Moriarty, acting district manager
1 Court Street	8 Merrimack Street
Tel. LA Fayette 7500	Tel. Lowell 6388
<i>Springfield</i>	<i>Worcester</i>
Lee Manley, district manager	G. W. Grebenstein, district manager
1200 Main Street	340 Main Street
Tel. Springfield 3-7857	Tel. Worcester 6-4391

At such an office, on presentation of his orders for separation under honorable conditions and his certification that the equipment is for use in his own professional enterprise, the veteran's application for the described property is approved on Form 66. He retains one copy, for use at the time of inspection or purchase of what he desires, and the other copy is forwarded to the appropriate disposal agency, which in the case of New England purchasers of medical equipment is the Consumer Goods Division, War Assets Corporation, 600 Washington Street, Boston. When this disposal station has acquired enough material to make a sale worth while, those veterans interested in the type of goods to be sold will be sent a catalogue, giving the stock number, Army nomenclature and price of the material offered and place where it may be inspected prior to the sale.

The veteran may be present in person at the sale or he may write to the disposal agency, giving his case number (from Form 66), applying for whatever articles he desires to purchase and enclosing a certified check. An opportunity to inspect the various items that are offered for sale may or may not be given, depending on the location of the stock. The sale to veterans will extend over a period of about two weeks on each lot offered.

To avoid disappointment, veterans should realize that they do not have the first choice on these goods. The first priority goes to federal agencies, and the second priority to agencies of a state, county or municipality. After these purchasers have been satisfied, the veteran has his chance, and what is then left is offered to nonprofit institutions, such as hospitals, and finally to the public. There is a movement on foot in the Congress to move the veteran doctor from the third priority class to the second.

MICHAEL A. TIGHE, M.D., Secretary

Some of them were fortunate, having had the opportunity to utilize their skills to the fullest. Others of equal attainment spent most of their time in "paper work," while holding rather exalted ranks, and still others were treated much as enlisted men, being ordered to do menial duties without any reference to their skills and training. REVIEW LECTURE COURSE

Two changes have been made in the program of the Postgraduate Review Lecture Course recently forwarded to all registered physicians in Massachusetts

In the first place, the time of the meeting on Wednesday, May 8, has been changed, the four speakers beginning their talks at 3 00, 3 45, 4 30 and 5 15, respectively

Secondly, the title of the exercise on Monday, May 13, has been changed from "Round-Table Discussion on Obstetrics in General Practice" to "A Critical Review of Progress in Obstetrics during the Last Four Years, including a Consideration of Certain Immediate Problems of the Newborn"

MASSACHUSETTS DEPARTMENT
OF PUBLIC HEALTHCOMMUNICABLE DISEASES IN
MASSACHUSETTS FOR FEBRUARY, 1946

RÉSUMÉ

DISEASES	FEBRUARY 1946	FEBRUARY 1945	SEVEN-YEAR MEDIAN
Anterior poliomyelitis	1	3	0
Chancroid	1	1	*
Chicken pox	764	1340	1347

†Four-year average

COMMENT

Measles, this month, showed a fourfold increase over last year's near record low. Mumps reached its lowest February figure in 10 years. Chicken pox was at its lowest since 1929.

Record low figures were reported for lobar pneumonia and tuberculosis, other forms.

The first cases of typhoid and anterior poliomyelitis for the current year were reported during February.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from Stoughton, 1, total, 1.

Diphtheria was reported from Arlington, 1, Boston, 7, Camp Edwards, 1, Gloucester, 2, Haverhill, 1, Lynn, 1, Malden, 1, Somerville, 2, Southampton, 1, Springfield, 1, Taunton, 2, Wellfleet, 1, total, 21.

Dysentery, amebic, was reported from Cambridge, 1, Revere, 1, Waltham (Regional Hospital), 1, total, 3.

Dysentery, bacillary, was reported from Marblehead, 3, Wrentham (State School), 6, total, 9.

Hookworm was reported from Camp Edwards, 1, total, 1.

Malaria was reported from Athol, 1, Bedford, 1, Belmont, 1, Beverly, 1, Boston, 17, Braintree, 1, Brockton, 1, Brookline, 1, Cambridge, 2, Camp Edwards, 7, Chelsea, 1, Dedham, 1, Everett, 2, Franklin, 1, Gardner, 2, Haverhill, 1,

Holbrook, 3, Leicester, 1, Leominster, 1, Lynn, 2, Lynnfield, 1, Malden, 3, Marblehead, 1, Marlboro, 2, Medford, 1, Melrose, 1, Methuen, 1, Milton, 1, Norwood, 2, Peabody, 4, Quincy, 2, Revere, 1, Rowley, 1, Salem, 1, Saugus, 1, Somerset, 1, Somerville, 3, Springfield, 2, Taunton, 2, Tyngsboro, 1, Wakefield, 1, Walpole, 1, Waltham, 2, Waltham Regional Hospital, 10, Wellesley, 1, Wilmington, 1, Worcester, 6, total, 102.

Meningitis, meningococcal, was reported from Boston, 4, Braintree, 1, Cambridge, 1, Everett, 1, Fall River, 3, Framingham, 1, Gloucester, 1, Leominster, 1, Lexington, 1, Milford, 1, Newton, 1, Southbridge, 1, Taunton, 1, Waltham, 1, Waltham Regional Hospital, 1, Worcester, 1, total, 21.

Meningitis, Pfeiffer bacillus, was reported from Fallmouth, 1, New Bedford, 1, total, 2.

Meningitis, pneumococcal, was reported from Boston, 1, Cambridge, 1, Everett, 1, Framingham, 1, total, 4.

Meningitis, undetermined, was reported from Cambridge, 1, Westfield, 2, total, 3.

Salmonella infections were reported from Brockton, 1, Cambridge, 4, Fitchburg, 1, Holyoke, 1, Norwood, 1, total, 8.

Septic sore throat was reported from Barre, 1, Boston, 7, Haverhill, 2, Merrimack, 2, North Adams, 1, Salem, 1, total, 14.

Tetanus was reported from Fall River, 1, total, 1.

Trichinosis was reported from Danvers, 1, Somerville, 1, Westport, 2, total, 4.

Typhoid fever was reported from Malden, 1, total, 1.

CORRESPONDENCE

A PLEA FOR THE GENERAL PRACTITIONER

To the Editor: Looking back over more than twenty-five years of general practice, with all their rough spots, as well as their smooth and pleasant ones, I feel grieved that the term "general practitioner," with its broad but plebeian meaning, has had no chance to lift itself from its lowly stratum in the medical world. How often the phrase, "He is a great specialist!" Has anyone ever heard, by chance, a remark such as, "It is remarkable how many things Dr. — can do, and do well"? It is certainly seldom uttered by a fellow physician, and a layman never makes the remark with the same sure confidence with which he tells the world "Dr. — is going to operate on my wife. He is a fellow of the American College of Surgeons." Hence my thesis, Why not an American College of General Practitioners?

What percentage of medical men are general practitioners? I certainly believe that they compose the majority. The economic exigencies of rural medicine make this statement sure. Throughout the history of medicine, it has been commonly recognized that general practitioners form the largest and most important subdivision of medical practice.

It is also true, that this group has furnished many men who have become outstanding in the medical world. We are indebted to the general practitioner for many of the outstanding advances in our science, and even if this were not so, the general practitioner is still in a position to evaluate the patient's complaints and physical findings and either treat the patient or intelligently refer him to one who can treat him better.

In my mind, the movement toward the narrower specialties may be directly traced to the fact that the general prac-

tioner has never been accorded his just professional recognition. To quote from an article by Dr. Russell L. Cecil in the May, 1945, issue of the *Medical Clinics of North America*: "during the last five decades a great variety of new specialties have appeared in the field, and many internists are devoting almost their entire time to such subjects as tuberculosis, diabetes, arthritis, allergic diseases and disorders of the endocrines. Personally, I believe this is a wholesome trend. However, it is very important for these highly specialized practitioners to maintain their contacts with the whole field of internal medicine. Otherwise, they become so narrow in their point of view that their approach to all medical problems is completely dwarfed. The rapid development of these subspecialties makes it difficult at times for the general practitioner to discover just what constitutes his domain today in the field of practice. Perhaps the establishment of group clinics will lead to a solution of these confused borderlines."

With a deep sense of respect and appreciation for all that Dr. Cecil stands for in the world of medicine, I cannot but feel that this statement tends to put the general practitioner more or less out on a limb. In spite of this, he warns these highly specialized practitioners, the specialists, to keep close to general practice lest they become narrow.

What have our medical societies done for this large cooperative and all too submissive majority of medical men called general practitioners except to accept their support to further the exclusiveness of and to create more fellowships and boards for the minority specialists?

For the purpose of furthering the cause or elevating the status of the general practitioner, to me it seems needless to discuss his comparative mental equipment. Does it not require as much training, ability and experience to do well almost everything pertaining to the care of the sick as it does to do expertly just one division of this whole? It may be the opinion of many of our specialists that the general practitioner of tomorrow will be a kind of trained greeter or steerer whose chief function will be to find the groove in which his patient is put to get to the proper specialist. Contrary to this thought, numerous writings appear from time to time in reference to the lot of the general practitioner. Dr. James L. Halliday in the June, 1943, issue of the *British Journal of Medical Psychology* expressed the following opinion: "Members of our profession are becoming increasingly separated in function and the medical outlook of each is tending to be constricted to some partial or special view. As a result, there is a tendency to ignore the underlying system of medical thought which unifies our diverse observations and activities and enables us to place them in a proper setting and perspective." In this same article, Dr. Halliday further states: "In the future of organized medicine, the general practitioner who has received a training in human biology will be pivotal in importance, and specialists will be regarded merely as his technical assistants."

Here and elsewhere, Dr. Halliday has ably pointed out the fallacies into which a mechanistic concept of disease must lead. Sound etiology will force us to accept old Cicero's dictum, *Nisi humani alicuius a me puto*, which, freely translated, means "There isn't a thing about my patient that I may not need to know." No system of medical records, no matter how skillfully contrived, can dispense with the integrating intelligence of a trained experienced mind. Here the sum of the parts is less than the whole. This integrating intelligence must stand near the beginning of the therapeutic process. There have been rhapsodies about the good old-fashioned family doctor. They are not all empty praise, although no doubt that good old fellow in the horse and buggy was paid half in cash and half in love, which was not the right formula. But we all know that the accomplishments of medical practice are not to be explained in engineering terms.

Now that I am no longer a general practitioner but have confined my work to internal medicine, I believe that it is not presumptuous of me to thus plead for recognition of the general practitioner. At the present time, any man who limits himself to a specialty, has, if qualified, an opportunity to pass the examination of a board and to become recognized by his fellows in his special field of work. This is true not only of the highly developed specialties, such as eye and x-ray, but also of the more comprehensive specialties, such as surgery and internal medicine. Why should not a well qualified general practitioner have the opportunity to pass a board examination in his general field that would put him

on equal footing with his brethren who have qualified in more limited fields?

With these thoughts in mind, why is it not feasible to establish the Board of General Practice or the American College of General Practitioners, or whatever it may be called, which would offer the same inducement to study and improvement that is accorded to men in other recognized specialties?

Those who have devoted years of study to the details of qualifications in the specialties would be able than I to specify eligibility regarding training, hospital experience, practical experience and the amount, if any, of formal post-graduate instruction.

I am cognizant of the fact that the difficulties of setting up proper standards in such an inclusive specialty would be greater than those that have been experienced in the more limited fields. I am sure, however, this is not an unsurmountable barrier. Certainly it is worth the attempt, and such action would be a potent factor in raising the standards of and making more attractive the practice of general medicine.

Should my hopes and pleadings bear fruit, I am sure that the family physician, an American institution with more tradition and sentiment than any other branch of American medicine, will find a new life incentive and goal to work for and that this will bring righteous recognition from his fellows. His will be a chance, similar to that of his confreres in the specialties, for appreciation and recognition by the millions whom he serves day and night, regardless of the physical or mental troubles with which they may be afflicted.

FRED C. ATKINSON, M.D.

257 Main Street
North Andover, Massachusetts

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

The Examination of Reflexes: A simplification. By Robert Wartenberg, M.D. With a foreword by Foster Kennedy, M.D. 12", cloth, 222 pp., with 7 illustrations. Chicago: The Year Book Publishers, Incorporated, 1945. \$2.50.

The author in this short manual has attempted to classify and unify the reflexes. Each reflex and the methods for testing and evaluation are discussed in a separate section. The important literature on the subject has been reviewed and noted in the text. A bibliography of 465 references is appended.

The Management of Obstetric Difficulties. By Paul Titus, M.D., obstetrician and gynecologist, St. Margaret Memorial Hospital, Pittsburgh, and consulting obstetrician and gynecologist, Pittsburgh City Homes and Hospital, Mayview and Homestead Hospital, Homestead, Pennsylvania. Third edition. 8", cloth, 1000 pp., with 426 illustrations and 8 color plates. St. Louis: C. V. Mosby Company, 1945. \$10.00.

The first edition of this authoritative reference work was published in 1937, and the second in 1940, this third edition has been extensively revised to bring it up to date and incorporate the new material of the past five years. Additions and changes have been made in the chapters on sterility, ante-partum care, the general management of pregnancy, labor and the puerperium and their complications. X-ray pelvimetry has been rewritten and simplified, and the chapters on toxemia in pregnancy have been thoroughly revised, with the addition of a proposed new classification of toxemias. The chapter on intravenous infusions and blood transfusions has been completely revised, and the related subjects of Rh incompatibilities and erythroblastosis brought up to date. Caudal analgesia has been added to the chapter on anesthesia. The technique of extraperitoneal cesarean section are described, with a number of detailed new illustrations. The use of penicillin in puerperal sepsis, gonorrhea and syphilis complicating pregnancy, and in pyelitis and other infections, as well as the dosage and technique of administration, are discussed in considerable detail. This book should be in the reference libraries of obstetricians and all physicians practicing obstetrics, as well as medical libraries, especially those of hospitals.

Courage and Devotion Beyond the Call of Duty Being a partial record of official citations to medical officers in the United States Armed Forces during World War II Preliminary edition 16", paper, 254 pp Evansville, Indiana Mead Johnson and Company, 1944

In this preliminary edition, short sketches are provided of various physicians who have received military and naval awards for courageous action in combat or for outstanding achievement in medical service. Short biographies are listed alphabetically, and each describes briefly the action for which the citation or award was made. This small book is unusual and a worth-while addition to the medical history of World War II.

Estudos Cirurgicos Vol 4 Eurico Branco Ribeiro, director of Sanatorio Sao Lucas 8", cloth, 280 pp, illustrated Sao Paulo, Brazil Libreria Atheneu, José Bernades, 1945

In this volume Dr Ribeiro has continued his collection of clinical cases covering the whole field of surgery. A number of the interesting cases are documented with selected lists of references to the medical literature. A combined index for the four volumes of studies has been appended to the text, making available all the cases in the four series, the first of which was published in 1934.

Penicillin Therapy, including Tyrothricin and Other Antibiotic Therapy By John A. Kolmer, M.S., M.D., Dr P.H., Sc.D., LL.D., L.H.D., professor of medicine, School of Medicine and School of Dentistry, Temple University, and director of the Research Institute of Cutaneous Medicine 8", cloth, 302 pp, with 22 illustrations and 20 tables New York D. Appleton-Century Company, Incorporated, 1945 \$5.00

This small book has been written for the medical and dental professions and is largely based on the literature for 1944 and 1945. Various methods of administration are fully discussed. Necessary laboratory procedures are included.

NOTICES

ANNOUNCEMENTS

Dr. R. Cannon Eley has returned from naval duty and will resume the practice of pediatrics at the Children's Hospital, 300 Longwood Avenue, Boston.

Dr. Benjamin Cohen announces his return from military service and the opening of an office for the practice of psychiatry and neurology at 520 Beacon Street, Boston.

Dr. James M. Faulkner, having returned from military service, is resuming the practice of internal medicine at 262 Beacon Street, Boston.

Dr. Calvin B. Faunce announces his return to the practice of otolaryngology at 290 Commonwealth Avenue, Boston.

Dr. Joseph Hahn, on termination of his military service, announces the reopening of his office at 121 Chestnut Street, Springfield.

Dr. Samuel Levine, having returned from military service, announces the opening of an office at 40 Baltimore Street, Lynn, for the practice of orthopedic surgery.

Dr. Henry M. Pollock, Jr., announces his separation from military service and the opening of offices for the practice of urology at 549 High Street, Westwood, and 536 Commonwealth Avenue, Boston.

Dr. N. S. Scarcello announces that he has been released from active duty with the United States Navy and will resume the practice of urology at 11 Irving Street, Worcester.

Dr. D. Thomas Staffier announces the removal of his office to 21 Breed Street, East Boston.

Dr. Jonathan Zonis announces the removal of his office from 300 Seaver Street, Roxbury, to 371 Commonwealth Avenue, Boston.

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday, April 9, at 8:15 p.m. Dr. Alvan L. Barach will speak on the subject "Treatment of Chronic Pulmonary and Sinus Infections." A discussion by Dr. Maurice S. Segal and Dr. Daniel Miller will follow.

NEW ENGLAND DERMATOLOGICAL SOCIETY

The regular annual meeting of the New England Dermatological Society will be held in the Skin Out-Patient Department of the Boston City Hospital on Wednesday, April 10, at 2:00 p.m.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston

Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCE PROGRAM

Wednesday, April 3 — Cerebral Hemorrhage Dr. R. D. Adams

Friday, April 5 — Experiences with the Use of Universal Donor Blood and Pooled Plasma Transfusions Dr. C. P. Emerson

Wednesday, April 10 — Medical Experiences in the Navy Dr. R. P. McCombs

Friday, April 12 — The Roentgenological Changes in the Gastrointestinal Tract in Scleroderma Dr. R. Schatzki

Wednesday, April 17 — The Diagnosis of Ruptured Membranes by the Vaginal Smear Dr. G. A. Bourgeois

Friday, April 19 — Holiday

Wednesday, April 24 — Atrophies, Hypertrophies, and Neoplasms of the Skin Dr. F. M. Thurmon

Friday, April 26 — Vagus Resection in the Management of Peptic Ulcer Dr. F. D. Moore

On Tuesday and Thursday mornings, Dr. S. J. Thannhauser will give medical clinics on hospital cases. On Saturday mornings, clinics will be given by Dr. William Dameshek. Medical rounds are conducted by some of the staff members from 12:00 to 1:00 in the Lecture Hall.

All exercises are open to the medical profession.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The general oral and pathological examinations (Part II) for all candidates will be conducted at Chicago, by the entire Board from Monday, May 6, through Saturday, May 11, 1946. The Palmer House in Chicago will be the headquarters for the Board. Formal notice of the exact time of each candidate's examination will be sent to him several weeks in advance of the examination dates. Hotel reservations may be made by writing direct to the Palmer House.

Candidates for re-examination in Part II must make written application to the secretary's office not later than April 15.

Candidates in military or naval service are requested to keep the secretary's office informed of any change of address. Deferment without time penalty, under a waiver of the published regulations applying to civilian candidates, will be granted if a candidate in service finds it impossible to proceed with the examinations of the Board. Applications are now being received for the 1947 examinations. For further information and application blanks, address Dr. Paul Titus, Secretary, 1015 Highland Building, Pittsburgh, 6.

Number 14

THE PENETRATION OF PENICILLIN THROUGH NORMAL AND INFLAMED MENINGES*

LIEUTENANT COLONEL J MURRAY KINSMAN, M C, A U S, AND

CAPTAIN C ANTHONY D'ALONZO, M C, A U S

FOLLOWING the demonstration that penicillin exhibits a remarkable antibacterial effect against organisms frequently causing meningitis, there immediately arose the question of the most effective mode of its administration in patients with these infections. Before penicillin was used in the treatment of meningitis, it was necessary to study its distribution in the body, particularly in the spinal fluid after extrathecal administration. Rammelkamp and Keefer¹ demonstrated that the meninges and the choroid plexus form a partial barrier against the passage of the drug from the blood stream into the spinal fluid, both in normal persons and in patients with meningitis. As a result of their investigations, it became the practice to give penicillin both extrathecally and intrathecally when it was used in purulent meningitis.

In general, the results with this combined form of therapy have been good.^{2,3} Recently, however, McDermott, Eagle and Nelson⁴ have shown that low concentrations—those of 0.02 units per cubic centimeter or less—of penicillin appear in the spinal fluid of normal persons several hours after massive parenteral doses. That inflamed meninges are more susceptible to the passage of penicillin than are normal ones was suggested by experiments in which constant amounts of the drug were injected intrathecally and assays of the blood and spinal fluid were performed at intervals thereafter. These studies showed that when the meninges are inflamed, the penicillin is absorbed from the spinal fluid more rapidly than it is in normal subjects.⁵ Evidence tending to confirm these observations has been presented by Fleming⁶ and more recently by Rosenberg and Sylvester.⁷ The latter reported that they had found penicillin in the spinal fluid in patients with meningitis who had been treated by the intramuscular or the intravenous route alone. Price and Hodges⁸ reported that 4 patients were cured, both clinically and bacteriologically, follow-

ing extrathecal therapy, 3 of them had meningococcal meningitis and 1 had pneumococcal meningitis. They mention 2 other patients in whom the cause of recovery was difficult to evaluate because they had received large doses of sulfonamides prior to penicillin therapy. In none of these cases were assays of the blood or spinal fluid performed. These observations have naturally suggested that intrathecal administration of penicillin is not necessary.

On the other hand, there is evidence that extrathecal therapy alone is sometimes inadequate. Some patients with pneumococcal pneumonia have developed pneumococcal meningitis while under treatment with penicillin administered by the intramuscular route.⁹ Moreover, in a few patients with pneumococcal⁹ and meningococcal¹⁰ meningitis there was a poor response to penicillin therapy until it was given intrathecally.

Because of the conflicting reports, it seemed advisable to obtain further information concerning the most efficient mode of administration of penicillin in patients with meningitis, this was considered especially important because of the comparatively high incidence of meningitis in wartime. Studies have been conducted in this hospital concerning the penetration of penicillin into and out of the spinal fluid. The results of these studies, together with certain clinical observations concerning the effectiveness of extrathecally administered penicillin in the treatment of meningococcal meningitis, comprise the present report.

ASSAY OF SPINAL FLUID FOLLOWING INTRATHECAL ADMINISTRATION

To determine how long penicillin persists in the spinal fluid after intrathecal administration, 4 patients with meningococcal meningitis were treated according to the following schedule: a dose of 25,000 units was given intravenously and one of 10,000 units intrathecally at the same time, one hour later, a dose of 25,000 units was given intramuscularly and repeated every three hours, the intrathecal injection was again administered at the

*From the Medical Service Regional Station Hospital Fort Bragg, North Carolina.
Part of this study was done under the direction of Lieutenant Colonel Worth C. Daniels, A. C., A. U. S.

eleventh hour Spinal fluid was collected for assay at the eighth and twenty-fourth hours. The specimens taken at the eighth hour contained 3.9 to 20.0 units per cubic centimeter, and those taken at the twenty-fourth hour contained 0.078 to 0.312 units. The penicillin content of the spinal fluid eight hours after the intrathecal injection of 10,000 units was thus shown to be far in excess of the minimum therapeutic requirement, and sixteen hours later, after a second intrathecal injection of 10,000 units, it was still at a therapeutically effective level. This indicates that when penicillin is used intrathecally for meningitis, it is not necessary to repeat the injections oftener than once every sixteen hours. Moreover, further observations in the same cases suggest that injection once every twenty-four hours is sufficient.

ASSAYS OF SPINAL FLUID FOLLOWING EXTRATHECAL ADMINISTRATION

In Patients Without Meningitis

More than 20 patients with early syphilis without meningitis were given intramuscular injections of 20,000 to 40,000 units of penicillin every three hours for one to eight days, and the spinal fluid was assayed at various intervals from the fifth to the eighth day. In no case was penicillin detected in the spinal fluid.

In Patients with Meningococcemia

Since it is now generally accepted that meningococcal meningitis is a sequel to or a metastatic form of a bacteremic phase, it was thought that in meningococcemia penicillin might possibly diffuse more readily into the spinal fluid than it does in normal persons. Specimens of the spinal fluid of 6 patients with meningococcemia who were being treated by penicillin were therefore collected for assay. Five of the patients received an initial dose of 25,000 units intravenously, which was repeated one hour later and then every three hours day and night. The spinal fluid was collected at the eighth and twenty-fourth hours of treatment in 4 cases and at the fifth and ninth days in 1 case. The sixth patient was on the same schedule, but in this case each dose was 40,000 units and the spinal fluid was collected at the eighth and twenty-fourth hours. In not one of the twelve specimens of spinal fluid was any penicillin detected, although in every case the clinical response to treatment was excellent and in no case did meningitis develop.

In Patients with Meningitis

Tuberculous meningitis Prior to making observations on patients with meningococcal meningitis, 2 patients with tuberculous meningitis were given penicillin by extrathecal injections and spinal fluid was obtained for assay. One patient was given five doses of 40,000 units each over a period of ten hours, the specimen of spinal fluid taken at the

eleventh hour contained a trace of penicillin, whereas that taken at the twenty-ninth hour contained none. The other patient received 40,000 units every three hours for eight doses, at the eighteenth hour no penicillin could be found in either the blood or the spinal fluid, whereas at the twenty-third hour the blood contained 0.4 units per cubic centimeter and the spinal fluid a trace of penicillin. In spite of large doses, therefore, only a trace of penicillin could be found in the spinal fluid after eleven hours of treatment in one case and after twenty-three hours of treatment in the other.

Meningococcal meningitis In view of the reported successes in treating meningococcal meningitis with penicillin administered only extrathecally, a study was made of the distribution of penicillin and its effectiveness in this disease when administered by the intramuscular route. Two case reports illustrating these points follow.

CASE 1 A 33-year-old soldier was admitted to the hospital on November 18, 1944, at 3:40 p.m. At 8 a.m. of that day he had had a chill, and he later developed a splitting headache. On admission he showed fever, an erythematous rash, marked rigidity of the neck, bilateral Kernig and Brudzinski signs, absent knee jerks and drowsiness. The spinal fluid contained 1540 cells per cubic millimeter, gram-negative intracellular diplococci were found on the smear, and Group I meningococcus was obtained from the culture.

It was decided to treat the patient with penicillin by the extrathecal route alone. Accordingly, at 5:45 p.m. he was given 40,000 units intravenously (Fig. 1). One hour later

FIGURE 1 Case 1

This is the temperature curve of a patient with meningococcal meningitis who was treated initially only with penicillin. The dotted lines under 1 in the penicillin dosage zone represent intrathecal injections.

he received 40,000 units intramuscularly, and this dose was repeated every 3 hours. During the next 24 hours the temperature fell to 99.6°F, the rash disappeared, the Kernig sign became less pronounced, the knee jerks returned, and the patient became less lethargic and drowsy. The headache, however, appeared to be as severe as ever. The spinal-fluid cell count rose to 9000 by 8:45 a.m. on November 19 and dropped to 3450 at 5:45 p.m., and the pressure fell from 210 to 125 mm (Table 1). All specimens subsequently yielded meningococci on culture. At 7:20 p.m. on November 19, 25 hours after the first dose of penicillin, the patient had a sudden chill, and the temperature rose to 102°F and a half-hour later to 103°F. At the same time the headache became still severer, the rigidity of the neck increased, the Kernig sign became more pronounced, and the patient became more lethargic. The spinal fluid obtained 1 hour after the chill contained 6200 cells, almost twice as many as did the speci-

men taken 3 hours previously, and the pressure had risen from 125 to 285 mm. At 9 p.m. sulfadiazine therapy was instituted in addition to the penicillin, which was continued, and from this time on the patient made a rapid and complete recovery. Blood cultures taken throughout the course of the illness were negative.

Comment For a while this patient appeared to be responding to penicillin, although the improvement was less rapid than that usually produced by sulfadiazine. Taking into consideration the clinical relapse and the supporting

established by examination of the spinal fluid, which contained 4650 cells per cubic millimeter and in which gram-negative intracellular organisms were demonstrated on smear (Table 3).

Because it was possible to keep the patient under close observation, it was decided to begin therapy with penicillin alone. This was begun at 10 p.m. on January 22 with a dose of 40,000 units intravenously and 40,000 units intramuscularly, the latter being repeated at 11 p.m., midnight and 1 a.m. and every 3 hours thereafter. There was some

TABLE 1 *Spinal-Fluid Findings in a Case of Meningococcal Meningitis (Case 1)*

	8 45 a.m.	140	Cloudy	9,000	93	Negative	Meningococcus Group I
	5 45 p.m.	125	Cloudy	3 450	88	Negative	Meningococcus Group I
11/20/44	8 45 p.m.	285	Cloudy	6,200	88	Negative	Negative
	5 45 p.m.	110	Cloudy	4 300	87	Negative	Negative
11/23/44	10 00 a.m.	68	Clear	6	50	Negative	Negative

bacteriologic evidence, however, the case must be definitely classified as one of failure of penicillin to effect a cure. It is of interest that the only time a measurable level of penicillin was present in the spinal fluid was 27 hours after parenteral therapy was instituted, shortly before sulfadiazine was administered (see Table 2).

CASE 2 An 18-year-old soldier was admitted on January 20, 1945. He apparently had a mild upper respiratory infection, and was about to be discharged on January 22 when

clinical improvement (Fig. 2) but not of a marked degree, and because the patient's condition remained poor, sulfadiazine therapy was begun on January 23, 20 hours after the first dose of penicillin. A little later the temperature rose to 105°F. Both sulfadiazine and penicillin were continued, and there was rapid and complete recovery. Blood cultures taken throughout the course were negative.

Comment As in Case 1, there was an initial improvement followed by a relapse and sulfadiazine was necessary for cure.

*Patient died at 35th hour after the first injection; spinal fluid was collected at autopsy 13 hours later.

†Patient died at 5th hour after the first injection; spinal fluid was collected at autopsy 2 hours later.

he had a chill, followed by fever. He gradually developed a splitting headache, a sore throat and stiffness of the neck. Examination later in the day showed a fine macular eruption, moderate rigidity of the neck, positive Kernig and Brudzinski signs and sluggish reflexes. By this time the patient was semicomatose. A diagnosis of meningococcal meningitis was

In this case the relapse occurred 20 hours after the institution of penicillin therapy as compared with 25 hours in Case 1. No penicillin was found in the spinal fluid at any time (see Table 2). Throughout the period of penicillin therapy the cell count remained elevated and both smears and cultures were positive.

Following these experiences there was felt a natural reluctance to attempt to treat other patients with penicillin by the extrathecal route alone. Since, however, Rosenberg and Sylvester⁷ had found penicillin in the spinal fluid in 8 patients at one and a half and two and a half hours after a single intramuscular injection of 40,000 units of penicillin, it was decided to attempt to confirm

3 cases (Cases 3, 4 and 5) of the 4 in which extremely large doses were given in the beginning

DISCUSSION

The studies reported herein indicate that although parenterally administered penicillin may penetrate into the spinal fluid in patients with meningitis, it does so irregularly and in relatively low concentrations. These observations do not confirm those of Rosenberg and Sylvester,⁷ who found measurable spinal-fluid levels in all of 10 cases of meningitis, with some values as high as 0.35 units per cubic centimeter. The differences are undoubtedly due in part to the fact that the assays in the present study were done by a modification of the Rammelkamp¹¹ serial dilution test, whereas Rosenberg and Sylvester used a turbidimetric method. A detailed discussion of assay procedures is beyond the scope of this paper, but in general it may be said that owing to the variable factor of lysis of sensitive staphylococci by penicillin, the reliability of turbidimetric methods such as that employed by Rosenberg and Sylvester is open to serious question. The fact that certain of the values that they obtained—as high as 0.35 units per cc—are so much higher than those in the present study following much larger doses of penicillin and than those obtained in other laboratories⁴ makes this explanation all the more probable.

The fact that the 2 patients in the present series who failed to respond to extrathecal therapy alone did not have measurable amounts of penicillin in the spinal fluid, except for a trace on one occasion, presumably indicates an inability of the penicillin

FIGURE 2 Case 2

This is another temperature curve of a patient with meningococcal meningitis who was treated initially only with penicillin

their results without jeopardizing the life of the patient by withholding other treatment. To be certain that a high concentration of penicillin was present in the blood stream, the doses used were large—at the outset a 40,000-unit dose was injected intravenously and the same dose intramuscularly. This dose was again given intramuscularly and 2 hours later. Specimens of blood and spinal fluid were collected for assay one and a half and two and a half hours after the beginning of treatment,

TABLE 3 Spinal-Fluid Findings in a Case of Meningococcal Meningitis (Case 2)

DATE	HOUR	APPEARANCE	NO OF CELLS	POLYMORPHONUCLEAR CELLS %	SMEAR	CULTURE
1/22/45	9 00 p m	Turbid	4 650	96	Meningococcus	Meningococcus Group I

after which the patients were placed on sulfadiazine. The results in 4 cases (Cases 3, 4, 5 and 6) are recorded in Table 2, which also incorporates the results in the 2 cases reported above and in 3 cases (Cases 7, 8 and 9) in which assays were done at odd intervals. These studies showed that penicillin may indeed penetrate into the spinal fluid, although it does so irregularly and in low concentrations. Concentrations of the order reported by Rosenberg and Sylvester—that is, up to 0.35 units per cubic centimeter—were not found in a single case, the highest level being 0.05 units. It should be emphasized that the blood levels were usually high—either 0.5 or 1.0 units per cubic centimeter—when measured at one and a half and two and a half hours after the beginning of treatment in

to penetrate readily into and through the meninges. This does not invalidate the favorable results obtained by Price and Hodges⁸ from administration by the extrathecal route alone, but merely emphasizes the variability and irregularity in the appearance of therapeutic concentrations of penicillin in the spinal fluid when the drug is given in this manner.

The recent studies of Meads and his associates¹² reveal important information concerning a subject closely related to the problem of parenteral versus intrathecal therapy. It was found that certain strains of meningococci were relatively resistant to penicillin, some of them so much so that even with intrathecal and extrathecal penicillin therapy combined the results were not so good as those obtained

with sulfadiazine. These observations indicate that if penicillin is to be used in the treatment of meningitis, the concentration in the meninges and spinal fluid should be high enough to be effective against the relatively resistant organisms occasionally encountered. From the present studies, it is evident that when given only extrathecally penicillin penetrates into the spinal fluid too irregularly and in concentrations too small to satisfy fully these requirements. An exception to this is syphilitic meningitis, in which penicillin administered intramuscularly appears to give excellent results^{12, 14}.

Four main points indicating that extrathecal therapy alone is not effective in meningitis have emerged from the present studies and from previous reports. These are the development of pneumococcal meningitis in patients receiving extrathecal penicillin therapy for pneumococcal pneumonia, the failure of many patients with pneumococcal and meningococcal meningitis to respond to penicillin until it was administered intrathecally, the low concentrations and irregularity of appearance of penicillin in the spinal fluid of patients with meningitis following extrathecal administration alone, and the fact that many cases of meningitis are caused by meningococci that are relatively resistant to penicillin.

It is therefore our opinion that patients with pneumococcal, streptococcal or staphylococcal meningitis should receive penicillin by both the extrathecal and intrathecal routes. For meningococcal meningitis, sulfadiazine is probably preferable to penicillin, but here too, if penicillin is administered, it should be given both extrathecally and intrathecally.

SUMMARY AND CONCLUSIONS

Because of the conflicting evidence for and against the intrathecal versus the extrathecal administration of penicillin in the treatment of meningococcal meningitis, a study has been made concerning the penetration of this drug into and through the spinal fluid.

When doses of 10,000 units of penicillin were injected intrathecally in patients with meningococcal meningitis who were also receiving moderately large doses intramuscularly, therapeutically effective amounts were still present in the spinal fluid sixteen hours later.

In more than 20 patients without meningeal involvement who were given intramuscular injections of 10,000 to 25,000 units of penicillin every three hours, penicillin was not found in the spinal fluid in a single case after five to eight days of therapy.

In 5 patients with meningococcemia without meningitis who received 25,000 units of penicillin

intramuscularly every three hours, and in 1 who was given 40,000 units on the same schedule, penicillin was not found in the spinal fluid in any case after eight and twenty-four hours of therapy in 5 cases and after five and nine days in 1 case. Every patient recovered, and in no case did meningitis develop.

In 2 patients with tuberculous meningitis who were treated extrathecally alone, only a trace of penicillin could be found in the spinal fluid — after eleven hours of treatment in one case and after twenty-three hours of treatment in the other.

In 9 patients with meningococcal meningitis who were treated during the early part of their illness with penicillin extrathecally only, assays of the spinal fluid were performed at various time intervals after the beginning of therapy. In some cases no penicillin could be demonstrated in the spinal fluid at any time up to thirty-five hours, in others small amounts, never larger than 0.05 units per cubic centimeter, were found. The appearance of penicillin in the spinal fluid after large extrathecal doses was irregular and inconstant.

The case histories of 2 patients with meningococcal meningitis who were treated with comparatively large doses of penicillin extrathecally are presented. In each case relapse occurred after an initial period of improvement — after twenty hours of therapy in one case and after twenty-five hours of therapy in the other. Both patients promptly recovered under sulfadiazine therapy.

Penicillin penetrates the meningeal barrier too erratically to justify its use extrathecally alone in purulent meningitis.

CLOSURE OF COLOSTOMIES

With Report of a Case

LIEUTENANT COLONEL PHILIP S FOISIE, M C, A U S *

THE abdominal cavity, on account of its size and central location, offers a conspicuous target for pieces of flying shell fragments, so that it is not surprising that every trainload of recently wounded patients arriving at an Army general hospital includes a fair number with abdominal injuries. Those that we have received were in fair condition on admission. In a few cases, the wound had been closed when exploration revealed no perforation of the bowel. In some, large hematomas had been found or other nonintestinal injuries had been repaired, but in the largest group of cases there was a history of bowel perforation, often multiple. In most of these, wounds of the small bowel had been sutured or resections had been done when the trauma was extensive. Many of these patients had primary closure with good results. In most cases of injury to the large bowel, the injured site had been exteriorized; and most cases that presented any great amount of bowel damage had received colostomy. Only in occasional cases did the record state that the limbs of bowel had been sutured together to form a well defined spur. By digital examination, however, it was possible to decide which cases were suitable for crushing, and most of the cases were prepared for closure in this manner. In 26 cases, colostomies were closed by applying clamps to reduce the septum between the bowel loops, and this was followed by simple transverse suture of the stoma, after the bowel had been freed to below the peritoneum and the adjacent rim of skin, with any protruding and edematous portion of the bowel, had been resected. It was usually found that this section of the bowel was fairly well walled off from the general peritoneal cavity by intraperitoneal adhesions, and no attempt was made to free them. After closure the bowel was dropped into the abdominal cavity and the peritoneum was closed over it, but the adhesions were not completely freed in the general peritoneal cavity. These patients had extremely little post-operative reaction or distention. Such a procedure can be carried out through a small elliptical incision, a small margin of skin around the stoma being excised, even when it is situated well in the flank or close to the inguinal region.

In only 2 cases were the loops resected and the free ends anastomosed. In one of these, a large mass of bowel had been exteriorized onto the abdominal wall following extensive injury to the descending colon. In the other case, a large amount of protruding bowel was eroded and thickened from exposure and was so situated laterally as to offer

little opportunity for freeing it up in situ. In this case the bowel was closed externally, covered with a rubber glove and brought back into the abdomen, and after resection of the entire mass a lateral anastomosis done.

Whether the limbs of bowel are sutured together to form a spur suitable for subsequent crushing or a loop of bowel is brought to the surface with no attempt to approximate its limbs, a certain amount of spur is bound to result. Efferent and afferent limbs adhere to some extent by their approximation in passing through the abdominal wall. All that is necessary to allow room enough for subsequent closure is to crush a portion of the intervening septum. Almost any type of surgical forceps is satisfactory for this purpose. The Kelly forceps suffices when only a small bite needs to be taken, but it is rarely comfortable to close the instrument to the first notch when it is first applied, and since it has no tooth at the tip, it is likely to slip off as the edema subsides. The Ochsner forceps overcomes this disadvantage but takes an extremely small bite. We generally use a pylorus clamp for the first application, employing the Kelly forceps later if a little more of the septum must be taken. The instrument is closed only to the point where it begins to be uncomfortable, and the bite is held with a strip of adhesive tape around the handles of the forceps. The slack can be taken up gradually every two or three hours with new strips as edema subsides until the first notch is reached. It is not necessary to apply two parallel clamps and slough out the central section. As soon as a cut is made in the septum it separates, and this forms an adequate lumen.

A practical criterion as to the adequacy of the preparation is the patient's ability to resume normal bowel movements. Patients admitted with evacuation occurring exclusively through the abdominal stoma begin to have normal defecations after some of the opposed bowel wall has been crushed. We have frequently tested this function by plugging the stoma with a vaseline gauze pack supported by a firm pressure dressing. This serves to encourage normal defecation if the lumen is adequate and also reduces any herniation of the bowel, as well as any edema in the exposed portion. Occasionally this results in complete reduction of the bowel beneath the skin margin and almost complete spontaneous closure. We have not waited for this to occur, however, since it still leaves bowel tied into the abdominal wall and requires unnecessary time. In such cases it is necessary only to excise the skin margin and close the small remaining opening into the bowel with a purse-string suture.

*Instructor in surgery, Tufts College Medical School and assistant to visiting surgeons, Boston City Hospital (on leave of absence)

The bowel can then be freed from the abdominal wall, the peritoneum closed over it, and the defect in the abdominal wall repaired. The wound is closed without drainage.

In some circumstances there is some question whether sufficient lumen has been left after closure

on the amount of lumen present. This is particularly true when the absence of a well defined spur has made it advisable to do little or no crushing. In such cases a transverse closure is done, and if it is thought that this has resulted in a questionably small lumen at the point of closure, an auxiliary

FIGURE 1 Completed Closure by Transverse Suture at the Site of Colostomy, with Anastomosis of Adjacent Loops in Cases in Which the Closure Leaves a Lumen of Questionable Adequacy

of the bowel. This happens when the opening is particularly large so that its inversion with two layers of sutures may have encroached too much

stoma is made by a lateral anastomosis of the adjacent limbs as they lie side by side in the portion of the bowel that traverses the abdominal wall

(Fig 1) This is done through the smooth longitudinal band of the antimesenteric margin, which can be easily approximated, since these loops of bowel are usually found bound together by adhesions incident to their displacement into the abdominal wall. In this way a satisfactory intestinal stream is re-established without sacrificing any blood supply to the bowel and without breaking through the protective walling-off process that to some extent at least seals off the local area of affected bowel from the general peritoneal cavity. Apart from the safety factor that this more conservative procedure affords, the postoperative course is milder than it is in cases in which resection and anastomosis are done.

PREOPERATIVE PREPARATION

As soon as colostomy patients are admitted, the record is studied to learn the extent and nature of the original bowel injury and to ascertain what was done at the forward hospital. A digital examination of the stoma is then made to determine whether the loops lie in close approximation and to gauge the thickness of the intervening septum. If the loops diverge immediately and there is a bulk of intervening tissue, no crushing is attempted. In most cases the two loops are found to lie parallel for several centimeters, with only a thin septum consisting of the two bowel walls, so that there is ample opportunity for crushing between them, even when the record makes no mention of the formation of a well defined spur. Clamps are applied as described above, several small bites being taken in preference to including too much tissue in the first application. The clamps usually fall off in three days, and a day or two more is allowed for any edema to subside before making a reapplication, if this is considered necessary. As a result of blood loss incident to the original injury and the emergency operative procedure, and because of the somewhat impaired nutrition secondary to the altered bowel habits, the blood picture in most of these cases is somewhat below normal. From one to three transfusions have been required to restore a normal circulation before any type of closure is done. There is a week of preoperative preparation after the patient appears to be anatomically ready for closure. During this period the proximal and distal loops are irrigated daily with warm saline solution and an occasional enema is given. Since no succinylsulfathiazole is available in this area, 1 gm of sulfaguanidine is administered every four hours during the week of preparation. A low-residue diet is given beginning four days prior to operation, and during the final twenty-four hours only clear fluids are given. Multi-vitamin preparations are given from admission until the patient has regained ability to tolerate a full diet postoperatively. A thorough cleansing of both loops of the colostomy is done on the evening before operation and again

just prior to leaving the ward for the operating room.

POSTOPERATIVE CARE

On the patient's return from the operating room the following routine is employed. A transfusion of 500 cc of whole blood is given immediately and is repeated if indicated. Drainage with a Wangenstein tube is done until flatus is being passed spontaneously and the abdomen is perfectly soft, this period averages three days. A dose of 3000 cc of 5 per cent glucose in normal saline solution is given daily until the patient begins to take fluids, and in some cases 1000 cc is given daily for one or two more days. Penicillin is administered, 40,000 units being included in each infusion.

The patient receives 16 mg of morphine every four hours for the first day and as needed thereafter. On about the third day the suction tube is clamped.

FIGURE 2 *An Abdominal Wound Caused by a Shell Fragment. The suture line of the exploratory incision has separated. There is a large defect in the lower abdominal wall opening directly into the abdominal cavity. A clamp has been applied to the colostomy spur. Note the extensive denuded area. Evacuation of the entire bowel drainage onto, and in fact into, this wound posed a difficult surgical and nursing problem.*

and the ingestion of small amounts of fluids by mouth is begun. If these are well tolerated, they are increased, and the patient is given a light diet for two days and then placed on a regular diet. There is usually normal defecation on the fourth day without an enema, and from then on convalescence is generally uneventful.

RESULTS

In this series of 26 cases, closure failed in only 1. In this case a small localized abscess was encountered alongside the bowel and deep in the abdominal wall.

In the face of this fact, no further freeing of the bowel was done, but it was closed in the hope of eliminating the fecal drainage as an aid to clearing up the infection. Drains of course had to be inserted into the abscess cavity. This closure broke down and fecal drainage persisted, and it took several weeks to clear up the infection in the abdominal wall. The patient finally had to be

subsequent paper on intestinal obstruction following abdominal wounds with bowel injury.

In 23 cases there were no complications. All these patients ran an extremely mild postoperative course and immediately developed normal bowel habits. They gained in weight and made general improvement, and were returned to the Zone of Interior in excellent physical and mental condition.

The case history of a patient with extensive abdominal trauma illustrates some of the many problems involved in the management of these cases.

A 35-year-old private was wounded on December 21, 1944, by a shell fragment which tore a large hole in the left lower quadrant of the abdominal wall. There had been evisceration of the ileum and jejunum with perforation of the jejunum and of the sigmoid colon. He had of course, experienced severe shock. On December 21 the jejunum was closed and the sigmoid exteriorized, and an unsuccessful attempt was made to close the abdominal wall.

The patient was evacuated to the United Kingdom on December 29, and was admitted to this hospital on January 2, 1945. The abdomen showed extensive loss of tissue (Fig 2). The operative incision had completely broken open

FIGURE 3 Photograph of the Same Abdomen at an Intermediate Stage

The midline wound has healed. The spur has been cut through, ready for closure of the bowel. There is still a large denuded area, which could not be grafted because of continual soiling. At this point, the patient was operated on, the colostomy was closed, the abdominal wall was repaired, and the skin defect was covered with split-thickness grafts.

evacuated with a persistent fecal fistula, but he was afebrile and had no further suppuration and had normal bowel movements as well. Final closure will have to be postponed until all inflammatory reaction has subsided. The patient was, however, gaining weight and doing well generally when evacuated to the Zone of Interior.

In 2 cases the wounds broke down slightly, with a small amount of fecal drainage for a few days. These wounds closed spontaneously, and there were no signs of peritoneal soiling.

There was 1 death in this series. It was caused by intestinal obstruction with massive gangrene of the bowel owing to adhesions resulting from the original trauma. The colostomy closure was functioning perfectly and was unrelated to the obstruction, which involved practically the entire small bowel, the latter being caught in multiple dense adhesions. This case will be discussed fully in a

FIGURE 4 The Final Result

The entire wound healed solidly, and normal bowel habits were restored. Note the skin grafts closing the defect seen in the previous illustrations.

and was held only by deep stay sutures. The bowel could be seen moving beneath the incision with respiration. Abdominal fluid welled up freely through the wound. A dark triangular area just medial to the colostomy opened into the abdomen and was constantly filled with feces. An area over the left iliac crest was completely denuded of skin, and the whole wound exuded with pus and feces.

The wound was strapped together with wide fenestrated strips of adhesive and was flushed several times a day, after the abdominal cavity had been protected as much as possible with wide strips of vaseline gauze. Cutting of the spur was begun at once (Fig 2). Several transfusions were given to build up the patient's general condition, and on January 9, under Sodium Pentothal anesthesia on the ward, a simple purse-string suture was applied to the colostomy in an at-

tempt to stop the fecal contamination of the open wound. This suture broke down in a few days. On January 17, a large abscess of the right thigh was drained. On January 30, pinch grafts were applied, and these stimulated the growth of points of epithelium that helped to close the wound. On February 24, a clamp was reapplied to cut the spur down a little more, and on March 5 preparation of the patient for closure of the colostomy was begun. There was still a large granulating area about the colostomy (Fig 3), but an adequate lumen had been established. On March 12, under spinal anesthesia, the bowel was freed and closed by a transverse suture. It was possible to close the peritoneum over the sutured bowel without completely freeing the intra-abdominal adhesions. There was some difficulty in repairing the defect in the abdominal wall owing to loss of fascia, but a flap of the external oblique muscle was used to close the wound securely. Split-thickness skin grafts were then applied, all the denuded areas on both sides of the colostomy being included.

The patient did extremely well. There was a small amount of leakage, which closed spontaneously, and the wound healed solidly (Fig 4). The patient developed normal bowel habits and gained in weight, and was returned home in excellent condition.

SUMMARY

The closure of colostomies in 26 cases following battle injuries is reviewed. Most of these were closed without resection and without completely freeing the bowel. In cases in which the local closure resulted in a lumen of questionable adequacy, an auxiliary stoma was made in adjacent loops. Thus, a satisfactory bowel continuity was re-established with a minimal sacrifice of blood supply and with a mild postoperative course.

In this series a fair amount of intraperitoneal walling-off has been encountered. The re-establishment of adequate bowel continuity and closure without disruption of this protective mechanism seemed to minimize the severity of the postoperative course and to offer some protection against leakage and soiling.

An interesting and difficult case is presented.

A NEW ANTISEPTIC SOLUTION FOR TOPICAL APPLICATION

Comparative In Vitro Studies

ETHAN ALLAN BROWN, M R C S (LONDON), L R C P (ENGLAND),* WILFRED KRABEK, M Sc,
AND RITA SKIFFINGTON, B Sc

BOSTON

THE earliest written records contain references to the use of germicidal agents.¹ The standard drug encyclopedias² list more than one hundred official and nonofficial preparations used for this purpose. The voluminous literature concerned with antiseptics attests to the intense study that has been given this subject, one of paramount importance in the field of medicine.

The ideal antiseptic for topical application must be stable, nontoxic, nonirritating and nonallergenic. It must act fairly quickly, yet its action in mixed infections must be relatively long lasting and effective. Its properties should permit its safe application to tissues as different as are the skin and mucous membranes, as well as to the highly specialized epitheliums of the eye and ear and, perhaps, of the genitalia. There must be no esthetic objections to its color, odor or other physical characteristics. Other considerations, such as availability and price, are secondary but nevertheless important factors.

With this and other points in mind, almost all available antiseptic solutions were studied and classified, but each was found wanting in one or more of the necessary qualifications. A review of the history of topical antiseptics reveals that one of the oldest of present-day solutions, hydrogen peroxide, possesses the greatest number of the above-

listed advantages. Not only are its constituent and end products innocuous, but it is intimately related to bacterial metabolism.³ It has fallen into disfavor because it suffers from two apparently major disadvantages: it is not stable in vitro, and its action in vivo is too transient to affect bacteria. The stabilization of hydrogen peroxide and the control of its rate of decomposition in catalase or peroxidase systems would open a new field in both peroxide chemistry and wound antiseptics.

It occurred to us that these problems could be solved by the use of carbamide peroxide as a solute and a source of hydrogen peroxide and that of anhydrous glycerol as a solvent. With the discovery that carbamide peroxide can be stabilized in alcohols and especially glycerol,⁴ it seems that such solutions may have unusual antiseptic properties.

Studies of the action of 4 per cent carbamide peroxide in glycerol on fusiform bacteria⁵ have shown that, by the agar-cup plate method, zones of inhibition are produced whose radial measurements from the edge of the cup to the edge of the zone are approximately 18 mm. A 0.125 per cent solution gives a zone of 5 mm. The glycerol control and the materials used for comparison—phenol (1 per cent), Pepsodent (undiluted) and Listerine (undiluted)—showed no zones of inhibition.

Further studies⁶ demonstrated that following the oral use of carbamide peroxide solution (2 per cent in 50 per cent glycerol and 50 per cent water),

*Instructor in medicine, Tufts College Medical School; consultant in allergy, Joseph H. Pratt Diagnostic Hospital; physician-in-chief, Allergy Clinic, Boston Dispensary.

the total number of viable bacteria in the oral cavity was reduced by 26 to 93 per cent for a period of two hours. The viable fusiform bacteria were reduced by 52 to 93 per cent. The number of bacteria, both viable and nonviable, were reduced by 10 to 62 per cent.

The use of this solution in 35 cases of chronic purulent otitis media⁷ gave the following results. Three patients showed no improvement, and 3 required additional treatment. The condition cleared completely in 29 cases within four to thirty-eight days, and in 17 cases within fourteen days. Equally encouraging results were achieved in the treatment of infections of the skin, eyes and mouth and in varicose and diabetic ulcers. These results will be reported in later articles. In all, the solution has been used by more than thirty physicians on more than 650 patients, in studies extending over a period of four years. The present paper, part of an extended series on antiseptics, is concerned with laboratory data, the solution being compared with a number of standard preparations for a series of organisms generally present in infections of the skin and mucous membranes.

The solution consists of 4 per cent carbamide peroxide in substantially anhydrous glycerol. Experiments with an 8 per cent solution are included, although its use in patients was followed on several occasions by slight transient irritation. For purposes of identification, the solution has been tentatively named *Thenardol*, in order that it may commemorate Jacques Louis Thénard (1777–1855), the discoverer of hydrogen peroxide.

On contact with water, the carbamide peroxide is split into carbamide (urea) and hydrogen peroxide. The presence of catalase or peroxidase in the tissues causes decomposition of the hydrogen peroxide into water and oxygen. In the concentrations present, none of the contained substances are toxic, irritating or allergenic.

The uses of urea as a peptizing agent are too well known to require listing.^{8,9} It should be noted at this point that all the previous studies concerning urea have dealt with its aqueous solution. Preliminary studies indicate that with the glycerol solution there is little or no absorption from wide areas of denuded tissues and no rise in nonprotein nitrogen.

The literature concerned with the antiseptic effects of hydrogen peroxide covers a period of more than sixty years, the greater part of it is unfavorable.¹⁰ Many of the authors who have worked in this field have noted that its relative ineffectiveness is chiefly due to its rapid decomposition and therefore transient action in aqueous solutions. None of this literature is pertinent, since little previous work has been reported regarding the action of hydrogen peroxide in glycerol, in which the rate of decomposition is relatively slow. Noteworthy work has been done by Melenev,¹¹ who since 1935

has worked with slow-acting peroxides, especially zinc peroxide, in watery suspensions, and by Reid and Altemeier,¹² who used the same peroxide in ointment form. The latter investigators state that the organic peroxides tend to be unstable but that urea peroxide in ointment form, if carefully made, remains stable. No details of the process of preparing the ointment are given. Our technic of preparation gives us an organic peroxide in stable liquid systems.⁴

The biochemistry of glycerol has been reviewed in detail.¹³ It has been stated¹⁴ that it is used more frequently in prescriptions than is any other substance except water. The ingestion of 30 cc three times daily for fifty days by 14 normal adults was found to be harmless.¹⁵ It should be noted that the absorption of glycerol, a factor to be considered in its application to large denuded areas, especially in diabetic patients, leads to the formation of glucose and glycogen.¹⁶

Although experimental work with wounds in animals¹⁷ has shown that glycerol holds granulations in check and permits epithelium to advance, not all authorities agree that this is clinically true. Glycerol solutions are said to cause irritation, owing in most cases to their dehydrating properties.

The term "irritation" requires definition so as to make it clear whether it refers to the subjective feelings of the patient or to the objective observations of the investigator. It is also necessary to consider the length of time the antiseptic solution has been used and the type of lesion to which it has been applied. Almost all substances, including water, retard healing if left in contact with damaged tissue for a sufficiently long time.

In 4 of our patients, there were complaints of a burning sensation but no objective changes could be seen. In another patient, no irritative effects were noted until the solution had been used as a continuous wet dressing on an infected anterior abdominal wall for fifty days.

It appears from preliminary clinical studies that glycerol solutions, although irritating at the point in the patient's progress at which the infection is under control and exudate is at its minimum, are less irritant than are any of the antiseptic tinctures that the physician is likely to use, either prophylactically or therapeutically, for the same type of lesion at the same time. Irritation is of concern only when it occurs before the infection has been checked. When it does so at a later date, it merely gives warning that the antiseptic should have been discontinued, however difficult it is to choose the moment at which this should be done.

In the present solution, the hygroscopic property of the glycerol constitutes a valuable adjunct to the chemotherapeutic process, since it draws plasma from the deeper parts of wounds, thereby washing out micro-organisms and exposing them to antiseptic action. Its viscosity gives it the mechanical

advantage of both the liquid and ointment types of medication. One of the special virtues of the solution is that it does not dry when used as a wet dressing in chronic infections.

Our studies were concerned with more than one hundred antiseptic solutions, of which the following six, used for comparison, were chosen for the present paper: tincture of iodine (*U S P*), Tincture of Mercresin (standard strength), Mercurochrome (2 per cent aqueous), Tincture Metaphen (1 200),

of a twenty-two-hour to twenty-six hour dextrose broth culture of the organism to be studied and poured into a 90-mm petri dish with an unglazed porous top. After the agar had hardened, a 1.5-cm cup was cut with a sterile cork borer, and a drop of melted agar was introduced into the cup to fill any cracks present. With a sterile pipette, 0.2 cc of the antiseptic to be studied was placed at the bottom of the cup. Replicate experiments were performed three or more times for each solution.

*The measurements are given in millimeters from the edge of the cup to the edge of the zone. The numbers in parentheses refer to the zones that gave positive subcultures and imply that the antiseptic solution at the point of subculture was bacteriostatic but not bactericidal.

Tincture of Phemerol (1 1000) and Zephiran Chloride Tincture (1 1000). The list includes a halogen, two mercurials, a mercury-phenolic compound and cationic agents dispensed as tinctures and as aqueous and glycerol solutions.

We appreciate the fact that 2 per cent aqueous Mercurochrome is not the vehicle in which the substance is said to show its greatest effects. Since it and the other solutions listed have been the subjects of study in all the forms in which they are available and will be reported in detail separately, mercurochrome was chosen as representative of an aqueous mercurial widely used for its supposedly antiseptic action.

These studies were concerned with the effects of antiseptic solutions on approximately forty pathogenic organisms, of which the following twelve are covered in this report: *Staphylococcus aureus* (FDA, Strain 209, and our own laboratory strain), alpha-hemolytic and beta-hemolytic streptococci, an enterococcus, *Micrococcus epidermidis*, a diphtheroid, *Proteus mirabilis*, *Pseudomonas pyocyaneus*, *Escherichia coli*, *Aerobacter aerogenes*, and *Eberthella typhosa*. The first seven organisms are gram-positive, and the remaining five are gram-negative.

The testing method used was a modification of the FDA agar-cup plate technic.¹⁸ Bacto dextrose agar, 35 cc (pH 7.3), was inoculated with 0.2 cc

and for each strain. The results were consistent within significant limits.

The plate was immediately incubated at 37°C and read after eighteen hours. Approximately 0.25 sq cm of the medium was removed for subculture, being taken at a point 2 to 5 mm in from the edge of the clear zone.

Dextrose agar was chosen as the medium so that maximum growth might be achieved for the greatest number of species with uniform conditions for all. Brewer's thioglycollate medium was chosen for the subcultures, since it detoxifies the mercurials and counteracts any residual peroxide. It seemed to have little or no effect on the cationic solutions, such as Zephiran. Considering the number of subcultures necessitated by this work and the relatively small zones obtained under the conditions of the experiments, the use of cationic detoxicants of the type mentioned by Valko and DuBois¹⁹ was not considered feasible.

The clear zone was measured radially in millimeters from the outside edge of the cup to the edge of the clear zone. When the zones were irregular in outline, five representative measurements were taken and an average figure was determined. When the zone edges were hazy, the exact zone was determined by subcultures taken

from the center of the plate toward the periphery. The results are listed in Table 1.

We are fully cognizant of the fallacies inherent in the conclusions that can be drawn from the type of test described. These have been ably discussed by Nve,²⁰ many of whose suggestions have

and 4 per cent Thenardol. The letters below the columns identify the organisms, according to the listing in Table 1. The negative sign (—) over a solid column evidences a negative subculture 2 to 5 mm central to the edge of the zone and implies that the column represents the zone of bac-

FIGURE 1 The Measurement of the Effects of Tincture of Iodine (U S P) on Twelve Common Organisms

been taken into consideration in this and the subsequent papers of the present series. The test is, however, a standard one. It does not control the effects of sublimation and so-called "creeping" for tincture of iodine and of creeping alone for other tinctures. The inhibitions produced by such solutions therefore suggest greater effectiveness than do exact measurements of actual bactericidal action, thus showing them to their greatest advantage.

tericidal power. An open column indicates that subcultures were positive and implies that the antiseptic was bacteriostatic rather than bactericidal. Subsequent reports will deal with the exact limitation of such zones of bacteriostasis, subcultures being taken radially at 2-mm intervals from the edge of the cup to the edge of the clear zone.

It will be seen from the tables that tincture of iodine gives the largest zones. As noted above

FIGURE 2 The Measurement of the Effects of Thenardol (4 per cent) on Twelve Common Organisms

The control of these qualities results in zones greatly reduced in size. Since this work has not become generally known, the traditional method has been used for the present paper.

The accompanying charts (Figs. 1 and 2) demonstrate the results for tincture iodine (U S P)

with correction for the effects of sublimation and creeping. These zones are reduced in size by 2 to 20 mm. The factors involved are varied and complex and require separate studies. This fact holds equally true for the other tinctures, although to a lesser extent.

The differences in effect on the members of the gram-positive (A-G) and the gram-negative (H-L) groups by the antiseptic solutions, especially the cationic detergents, as shown in Table 1, is worth noting. The antiseptics have been arranged in the approximate order of potency, as measured by the agar-cup plate method. As noted above, the measurements were taken radially from the edge of the cup to the edge of the zone in millimeters. Whenever subculture material was positive, the zone was considered one of bacteriostasis. In this event the measurements are enclosed in parentheses. Otherwise, the measurements refer to zones of bactericidal effect as proved by negative subcultures.

Since replicate experiments showed the behavior of the antiseptic solutions to be consistent for each organism, the inconsistent effects of differing organisms should be noted. Tincture of iodine and 8 per cent Thenardol demonstrated excellent bactericidal power. With 4 per cent Thenardol there were positive subcultures for the diphtheroid group. Tincture Metaphen appeared to be bacteriostatic for the staphylococci used and, in the gram-negative group, for *P. mirabilis*, *Ps. pyocyaneus* and *Esch. coli*. Tincture of Mercresin was bacteriostatic for seven of the bacteria, the subcultures being negative for the enterococcus, *M. epidermidis*, *Esch. coli* and *A. aerogenes*. For technical reasons, the results for *E. typhosa* have been omitted, the zone having been too irregular to be read with accuracy. Mercurochrome gave small zones for all the organisms, with positive subcultures for seven. Its effects were apparently less uneven than those of the other solutions studied. The action of Zephiran Chloride Tincture was extremely irregular, with little or no demonstrable effect on *P. vulgaris*, *Esch. coli* and *E. typhosa*. Tincture of Phemerol showed almost no bactericidal power for nine of the twelve bacteria. It affected the standard staphylococcus but not the laboratory strain, a much more resistant organism.

If tincture of iodine is taken as a standard, the great difference between its bactericidal power and those of the other solutions studied is quite remarkable and should do much to outweigh its irritant, toxic and allergenic properties, especially since the mercurials are themselves not free of these same faults. The agar-cup plate technic therefore appears to corroborate the previous studies, especially those of Nye,²⁰ who reached the same conclusions although using other technics in the evaluation of iodine

solutions. Since iodine cannot, however, be used either for applications at frequent intervals or for continuous wet dressings, search for other solutions possessing some of its qualities and adapted for these uses must be made.

SUMMARY

The composition and properties of a new antiseptic solution that is neither toxic, irritant nor allergenic are described. A comparison between it, tincture of iodine and five commercial antiseptic solutions by the agar-cup plate method, with the use of twelve commonly occurring micro-organisms, demonstrates its bactericidal efficacy. Its chemical, physical and bactericidal properties seem to commend its use in mixed infections of the skin and mucous membranes.

Although the perfect antiseptic for topical application in mixed wound infections has not yet been discovered, carbamide peroxide in glycerol or similar solutions appears to approach this goal.

PAPILLOMA OF THE GALL BLADDER*

DAVID MILLER M D †

NEW YORK CITY

IN THE general problem of biliary disease, the relatively infrequent occurrence or recognition of papilloma of the gall bladder is of interest. This report was prompted by the recent finding of 3 cases within the last few months. In each case the preoperative diagnosis was correctly made by the roentgenologist.

Estimations of the frequency of occurrence of papillomas vary, depending on the criteria for histologic diagnosis of these tumors. Kerr and Lendrum,¹ whose criteria were most exacting, had accepted only 7 cases up to 1936. To these was added a case reported by Brown and Cappell² and accepted by the previous authors. On the other hand, in the American literature, Irwin and MacCarty³ found 85 cases of papilloma of the gall bladder in 2168 cases of gall-bladder disease, and C. H. Mayo⁴ found 107 cases in 2538. Kirklin⁵ reported an incidence of 8.5 per cent of gall bladders containing one or more papillomas in 1700 patients undergoing cholecystectomy at the Mayo Clinic during a period of about six years. Recently, Greenwald⁶ reported a series of cases similar to those discussed below.

Although polypoid lesions of the colon and the urinary bladder have a significant association with carcinoma of these organs, this does not appear to be important in the present connection. Phillips⁷ in his series of 500 cases found 1 case in which carcinoma occurred in a papillomatous gall bladder. Kerr and Lendrum¹ reported 3 cases of carcinoma in patients who had gall bladders containing papillomas. I am not aware of any other similar cases.

In the following cases, the abdomen was surgically explored and the gall bladder was removed because of the presenting symptoms, rather than because of the possibility of cancer. The latter can never be ruled out, however, without histologic examination. It is not unreasonable to expect that in rare cases an early carcinoma near the fundus of the gall bladder will be found in cases in which the preoperative diagnosis is papilloma.

CASE REPORTS

CASE 1. A. K. W. (DH-40999), a 36-year-old, married woman was admitted on July 27, 1944, complaining of attacks of nonradiating pain in the right upper quadrant of the abdomen of 3 years' duration. The attacks occurred at 2-month intervals and followed the ingestion of fatty or fried foods. There had been no fever, chills or jaundice. Twelve years previously, the patient had a cesarean section. She had had no other operations and no significant illnesses.

Physical examination was essentially noncontributory. Roentgen-ray examination by Dr. Alice Ettinger at the Pratt Diagnostic Hospital, Boston, revealed papillomas of the gall bladder.

*From the Surgical Service of Dr. Ralph Colp, Mount Sinai Hospital.
†Adjunct surgeon, Beckman Hospital, member of staff, out-patient department, surgical clinic, Mount Sinai Hospital.

The patient was operated on by Dr. Ralph Colp. Exploration of the abdomen revealed a gall bladder of normal size with a slightly thickened wall. Cholecystectomy and appendectomy were performed.

Gross examination of the mucosal surface of the gall bladder showed four papillomas, each 0.5 cm. long, attached by thin pedicles. They were the same color as the rest of the mucosa and somewhat translucent. Microscopic examination of these tumors showed tufts of thin stroma lined with columnar cells (Fig. 1), some of the tufts were stuffed with large clear lipid-

FIGURE 1 Case I

A low-power photomicrograph showing the papilloma attached by a thin pedicle to the mucous membrane of the gall bladder.

bearing cells. The surface epithelium of the gall bladder mucosa was otherwise normal. The wall of the organ showed an increase in fibrous tissue and round cells. The appendix was normal on gross and microscopic examination.

The patient was relieved of her symptoms and made an uneventful recovery.

CASE 2. D. B. (DH-42485), a 46-year-old, married man, was admitted in November, 1944, complaining of attacks of pain in the right upper quadrant of the abdomen, radiating to the right shoulder and scapular region, of several months' duration. For an indefinite period of time he had had postprandial distress and flatulence. On rare occasions he had had some nausea and vomiting. He had never had fever or jaundice with attacks of pain. The past history revealed nothing of importance except hay fever.

Physical examination was essentially normal except for slight tenderness in the right upper quadrant. Roentgenograms of the gall bladder were interpreted by Dr. Arthur Bendick as showing papillomas.

Exploratory laparotomy was performed by Dr Ralph Colp on November 9. The gall bladder was distended with dark-green bile and contained several stones. When it was removed and opened, it was seen to contain two papillomas 1 cm in length. Microscopically, these consisted of piled-up villi with a thin fibrous core lined with columnar epithelium (Fig. 2). The wall of the gall bladder and the mucous mem-

FIGURE 2 Case 2

A low-power photomicrograph showing the papilloma, which has complex processes

brane were otherwise normal. The common duct was not dilated and contained no palpable stones. There were no other abnormalities.

The patient recovered from the operation uneventfully and has been well to the present.

CASE 3 J. M. (MSH-431865), a 35-year-old man, who was admitted in March, 1945, had had vague episodes of dyspepsia over a period of 8 months. These were unrelated to the ingestion of any particular foods. Three weeks before admission he had an attack of epigastric pain, which was relieved by the repeated belching of gas. Similar attacks ensued at irregular intervals. Six hours before admission, non-radiating epigastric pain and distress began and persisted. There was no vomiting.

On physical examination there was moderate tenderness in the right upper quadrant of the abdomen. The patient was afebrile. No mass was palpable. The white-cell count was 16,000, with 90 per cent neutrophils.

The patient was given intravenous glucose and saline solution, and the symptoms subsided within a few hours. Subsequent roentgen-ray examination of the gall bladder showed two radiotranslucent areas, which did not shift in position as the patient was moved (Fig. 3). Dr Marcy Susman's diagnosis was papilloma of the gall bladder.

The patient was operated by Dr Ralph Colp on March 20, 1945. The gall bladder was thin-walled. The stomach was normal. The gall bladder was removed and opened, and two papillomas of split-pea size were seen on the mucous membrane, to which they were attached by thin pedicles. There was an elevated area of mucous membrane 0.5 cm in diameter above the surface of the mucosa. There were also present two bright-orange excrescences 1 to 2 mm in diameter. There were no stones.

The patient has remained well since operation.

DISCUSSION

The etiology of these tumors is a matter of speculation. Infection may play a significant part. Of the 500 cases reported by Phillips,⁸ 255 (51 per cent) occurred in association with chronic catarrhal cholecystitis. In contrast to carcinoma of the gall bladder, the presence of stones in papilloma of the gall bladder seems to have no etiologic significance. Stones were present in 26.8 per cent of Phillips's series. Carcinomas of the gall bladder are associated with stones in 65 per cent to 90 per cent, various series. Polypoid excrescences occur in the so-called "strawberry" gall bladder. These contain deposits of cholesterol, discernible to the naked eye as yellow masses. Such masses may form the nuclei for stones.

Phillips⁸ states that infection and metabolic disturbances, often working together, may play a role in the etiology of these tumors. The nature of the metabolic disturbance is not clear. In a number of cases described by him, papillomas were present in a strawberry gall bladder.

The papillomas appear as projections from the mucous membrane of the gall bladder. Their core is that of the mucous membrane. The pedicles may be so thin that the new growth is easily brushed off or so broad that the mass is firmly attached. These projections may appear in any portion of the organ, but they occur oftenest at its neck or midportion. Microscopically the growths consist of branching complex processes of thin stroma lined with columnar cells.

In the large series of reported cases, the majority of cases usually occur after the third decade of life. The ages in the present cases were thirty-five, thirty-six and forty-six years, respectively.

The symptoms that bring the patient under observation are similar to those of chronic cholecystitis. Intolerance to fatty or fried foods, dyspepsia, flatulence and attacks of pain in the epigastrium and right upper quadrant of the abdomen occur. Fever, chills and jaundice are not usually noted. The patient comes to operation at any time from months to years after the onset of symptoms. It is not clear why these papillomas, often unassociated with stones or infection, produce symptoms. One is forced to indict a vague metabolic disturbance as a causative agent. Relief of the symptoms is obtained by cholecystectomy.

The preoperative diagnosis can be readily made with a high degree of assurance by roentgen-ray examination. In a series of 15 cases of papilloma, Kirklin⁶ was able to diagnose 14 preoperatively. He states that the best time for examination is the twentieth hour after the ingestion of dye. Stones usually change their position with succeeding examinations, are often bunched together and are most frequently found at the fundus. Most papillomas are discrete, do not change position and are

rarely found at the fundus. Adenomas are usually larger than papillomas, measuring 2 cm or more in diameter, as against 0.5 cm to 1.0 cm, and are frequently present at the fundus. Sarcomas are exceedingly rare, only 13 cases having been recorded in the literature.

Since the majority of carcinomas arise near the neck of the gall bladder, the organ is obstructed and damaged and cannot be accurately visualized.

When the papillomas give rise to symptoms, the treatment is surgical. Cholecystectomy should be performed, since it gives relief. Unless jaundice has been noted preoperatively or operation reveals a dilated common duct with an intrinsic palpable mass or many small stones, the common duct need not be opened. Colp¹¹ pointed out in a recent paper that between 30 and 40 per cent of cholecystectomized patients have attacks of pain similar to those

FIGURE 3 Case 3
Gallbladder at twenty-one hours filled with dye and showing 100 faint translucent areas

Sosman,⁹ in his recent excellent paper on the radiologic aspects of gall-bladder disease, stated that he had never made a diagnosis of carcinoma of the gall bladder by cholecystography. Furthermore, Sussman¹⁰ does not recall having made such a diagnosis. For details of the technic of cholecystography, the papers by Sosman⁹ and Kirklin⁵ should be consulted.

that preceded operation. These attacks usually occur within two years of the operation and may be temporary. In cases in which stones had been present, this postcholecystectomy syndrome was encountered less frequently.

CONCLUSIONS

1. Papillomas of the gall bladder are rarely associated with carcinoma.

Exploratory laparotomy was performed by Dr. Ralph Colp on November 9. The gall bladder was distended with dark-green bile and contained several stones. When it was removed and opened, it was seen to contain two papillomas 1 cm in length. Microscopically, these consisted of piled-up villi with a thin fibrous core lined with columnar epithelium (Fig. 2). The wall of the gall bladder and the mucous mem-

FIGURE 2 Case 2

A low-power photomicrograph showing the papilloma, which has complex processes

brane were otherwise normal. The common duct was not dilated and contained no palpable stones. There were no other abnormalities.

The patient recovered from the operation uneventfully and has been well to the present.

CASE 3 J. M. (MSH-431865), a 35-year-old man, who was admitted in March, 1945, had had vague episodes of dyspepsia over a period of 8 months. These were unrelated to the ingestion of any particular foods. Three weeks before admission he had an attack of epigastric pain, which was relieved by the repeated belching of gas. Similar attacks ensued at irregular intervals. Six hours before admission, non-radiating epigastric pain and distress began and persisted. There was no vomiting.

On physical examination there was moderate tenderness in the right upper quadrant of the abdomen. The patient was afebrile. No mass was palpable. The white-cell count was 16,000, with 90 per cent neutrophils.

The patient was given intravenous glucose and saline solution, and the symptoms subsided within a few hours. Subsequent roentgen-ray examination of the gall bladder showed two radiotranslucent areas, which did not shift in position as the patient was moved (Fig. 3). Dr. Marcy Sussman's diagnosis was papilloma of the gall bladder.

The patient was operated by Dr. Ralph Colp on March 20, 1945. The gall bladder was thin-walled. The stomach was normal. The gall bladder was removed and opened, and two papillomas of split-pea size were seen on the mucous membrane, to which they were attached by thin pedicles. There was an elevated area of mucous membrane 0.5 cm in diameter above the surface of the mucosa. There were also present two bright-orange excrescences 1 to 2 mm in diameter. There were no stones.

The patient has remained well since operation.

DISCUSSION

The etiology of these tumors is a matter for speculation. Infection may play a significant part. Of the 500 cases reported by Phillips,⁸ 255 (51 per cent) occurred in association with chronic catarrhal cholecystitis. In contrast to carcinoma of the gall bladder, the presence of stones in papilloma of the gall bladder seems to have no etiologic significance. Stones were present in 26.8 per cent of Phillips's series. Carcinomas of the gall bladder are associated with stones in 65 per cent to 90 per cent of various series. Polypoid excrescences occur in the so-called "strawberry" gall bladder. These contain deposits of cholesterol, discernible to the naked eye as yellow masses. Such masses may form the nuclei for stones.

Phillips⁸ states that infection and metabolic disturbances, often working together, may play a role in the etiology of these tumors. The nature of the metabolic disturbance is not clear. In a number of cases described by him, papillomas were present in a strawberry gall bladder.

The papillomas appear as projections from the mucous membrane of the gall bladder. Their color is that of the mucous membrane. The pedicles may be so thin that the new growth is easily brushed off or so broad that the mass is firmly attached. These projections may appear in any portion of the organ, but they occur oftenest at its neck or midportion. Microscopically the growths consist of branching complex processes of thin stroma lined with columnar cells.

In the large series of reported cases, the majority of cases usually occur after the third decade of life. The ages in the present cases were thirty-five, thirty-six and forty-six years, respectively.

The symptoms that bring the patient under observation are similar to those of chronic cholecystitis. Intolerance to fatty or fried foods, dyspepsia, flatulence and attacks of pain in the epigastrium and right upper quadrant of the abdomen occur. Fever, chills and jaundice are not usually noted. The patient comes to operation at any time from months to years after the onset of symptoms. It is not clear why these papillomas, often unassociated with stones or infection, produce symptoms. One is forced to indict a vague metabolic disturbance as a causative agent. Relief of the symptoms is obtained by cholecystectomy.

The preoperative diagnosis can be readily made with a high degree of assurance by roentgen-ray examination. In a series of 15 cases of papilloma, Kirklin⁵ was able to diagnose 14 preoperatively. He states that the best time for examination is the twentieth hour after the ingestion of dye. Stones usually change their position with succeeding examinations, are often bunched together and are most frequently found at the fundus. Most papillomas are discrete, do not change position and are

lowing discharge, or are followed in their homes by visits at intervals of a week to a few times a year. Lichtenstein describes his method of treatment as follows

Fresh cases receive from the onset "free diet" [By this Lichtenstein means a diet completely corresponding with that of healthy children] The diabetic children are allowed at first to take the ordinary hospital fare and eat their fill. In their homes they are then allowed to share the diet of their brothers and sisters and playmates and to satisfy their individual taste within the same limits as for healthy children. Even sugar and sweets in reasonable amounts are permissible. At the hospital the amounts of food which the children *spontaneously* consume are weighed and measured. In their homes no weighing or measuring of the food is required. The only restriction made is to avoid overindulgence, a rule that should apply in equal degree to all children, thus also to healthy ones.

The children receive the amount of insulin required to produce a good general condition, a feeling of well-being, a satisfactory increase in weight, a moderate amount of urine and complete freedom from acids in the urine. On the other hand, I attach less importance to a moderate rise in blood sugar and to a moderate or small excretion of sugar, in itself. Indeed, I prefer some excretion of sugar to complete freedom from sugar in the urine, as one then runs a smaller risk of hypoglycemia and ketosis, the two dangers that in the first place menace the diabetic child.

The transition between dietetic treatment and "free diet" could always be made without difficulty. Thus children who had previously received a diet of less than 100 gm of carbohydrate per day, during the first few days of the "free diet" consumed 250 to 300 gm of carbohydrate per day. After a few days, however, they spontaneously adjusted themselves to a more moderate consumption of carbohydrates, which, however, was always considerably higher than the amount previously permitted. As a rule it was about 150 to 250 gm per day, corresponding to 6 or 7 gm per kilogram of body weight.

These children spontaneously consume as a rule 2 or 3 gm of protein and 2.5 to 3.5 gm of fat per kilogram per day. The supply of calories was as a rule spontaneously maintained at 80 to 100 for children under five, at 60 to 80 at the age of five to ten years and at 40 to 60 at the age of ten to fifteen years, all per kilogram of body weight.

The general condition of the patients is recorded throughout as extremely satisfactory, with no increased hunger, thirst or polyuria. They are said to have had a feeling of well-being and joy of life, in contrast to the regime that marked them out from healthy children. Growth in height and weight, with a few isolated exceptions, were well within the normal limits for healthy children in Sweden. No difficulties were encountered during puberty. As regards the carbohydrate metabolism, the presence of sugar in the urine up to some tens of grams of sugar for twenty-four hours was not considered a cause for concern provided that the patients felt well, and showed no increase in hunger or thirst, polyuria or itch. As a rule, the degree of glycosuria was less than 10 per cent of the carbohydrate intake. As a result of these measures, severe attacks of hypoglycemia were, in fact, extremely rare.

The blood-sugar fasting values in most well controlled cases ranged between 100 and 200 mg per 100 cc.

Lichtenstein believes that the patients reacted better to infections than they did on the previously restricted diets. There was only 1 death from miliary tuberculosis, and of 41 patients who sooner or later

showed a positive tuberculin reaction, only 1 developed a lung focus, and thus healed. Neither increase in blood pressure nor demonstrable calcification of the blood vessels was observed. The cholesterol, as a rule, was below 230 mg per 100 cc. In 1 case there was a slight unilateral cataract, and in a number of cases there was a slight transient enlargement of the liver.

Lichtenstein's mortality was low. Of the 169 patients, only 8 died. One was murdered, 1 succumbed to miliary tuberculosis with meningitis a few months after the onset of diabetes, 1 died of pleural empyema with peritonitis and one of scarlet fever, 1 died of oral infection, and 3 died of coma. The mortality rate for the ten-year period was 4.7 per cent. Lichtenstein compares this rate with that of my cases, as reported by White,⁵⁰ which was 8 per cent for 150 cases of fifteen years' duration. A comparison to be valuable should be made between children with similar durations of diabetes. It should be added that the mortality of this clinic will be still higher in the 249 cases that are of twenty years' duration and are soon to be reported.

Hagedorn's protamine insulin was used in Lichtenstein's cases instead of protamine zinc insulin. The dosage varied between 10 and 120 units a day, the average being about 40 units. The maximum dose of regular insulin averaged about 60 units. Lichtenstein also frankly points out

To obtain good results, one must exercise a careful, continuous control, with at first frequent and gradually more occasional examinations. In the case of children, the control involves good co-operation with the homes, especially with the mothers. It is therefore necessary to give instructions to the mothers. They must learn the principal features in the clinical treatment of the disease, they must learn to recognize, in particular, such changes in the child's condition as require a modification of the insulin dosage, and they must learn to use the insulin syringe correctly. Many mothers in our Swedish clientele can be taught to make qualitative and sometimes also quantitative sugar tests and even to perform Gerhard's and Legal's tests for ketone bodies in the urine. A more important matter, however, is to draw their attention to the significance of *greater thirst* and *large amounts of urine* as indications of unsatisfactory adjustment, and to the importance of immediately getting in touch in such cases with the doctor treating the case. Another important matter is to get the mothers to understand the *signs of hypoglycemia* and how it is connected. The importance of a *regular conduct of life* with regular meals should also be strongly emphasized.

My own aversion to the treatment advocated by Lichtenstein arises not so much from the actual diets that he employs — which, as a matter of fact, differ little from the average diet now generally given to diabetic children — as from the psychologic effect on the children and the parents of growing up with the belief that their diabetes can be controlled by insulin and not by diet, insulin and exercise. It is the old, old story — a compromise with evil that a possible good may come. Seneca wrote, "We may lay it down as an invariable axiom in all high education that it is never sensible to permit what is bad for the supposed sake of preventing what is worse." In the education of his pupil Nero,

lowing discharge, or are followed in their homes by visits at intervals of a week to a few times a year. Lichtenstein describes his method of treatment as follows:

Fresh cases receive from the outset "free diet" [By this Lichtenstein means a diet completely corresponding with that of healthy children.] The diabetic children are allowed at first to take the ordinary hospital fare and eat their fill. In their homes they are then allowed to share the diet of their brothers and sisters and playmates and to satisfy their individual taste within the same limits as for healthy children. Even sugar and sweets in reasonable amounts are permissible. At the hospital the amounts of food which the children spontaneously consume are weighed and measured. In their homes no weighing or measuring of the food is required. The only restriction made is to avoid overindulgence, a rule that should apply in equal degree to all children, thus also to healthy ones.

The children receive the amount of insulin required to produce a good general condition, a feeling of well-being, a satisfactory increase in weight, a moderate amount of urine and complete freedom from acids in the urine. On the other hand, I attach less importance to a moderate rise in blood sugar and to a moderate or small excretion of sugar, in itself. Indeed, I prefer some excretion of sugar to complete freedom from sugar in the urine, as one then runs a smaller risk of hypoglycemia and ketosis, the two dangers that in the first place menace the diabetic child.

The transition between dietetic treatment and "free diet" could always be made without difficulty. Thus children who had previously received a diet of less than 100 gm of carbohydrate per day, during the first few days of the "free diet" consumed 250 to 300 gm of carbohydrate per day. After a few days, however, they spontaneously adjusted themselves to a more moderate consumption of carbohydrates, which, however, was always considerably higher than the amount previously permitted. As a rule it was about 150 to 250 gm per day, corresponding to 6 or 7 gm per kilogram of body weight.

These children spontaneously consume as a rule 2 or 3 gm of protein and 2.5 to 3.5 gm of fat per kilogram per day.

The supply of calories was as a rule spontaneously maintained at 80 to 100 for children under five, at 60 to 80 at the age of five to ten years and at 40 to 60 at the age of ten to fifteen years, all per kilogram of body weight.

The general condition of the patients is recorded throughout as extremely satisfactory, with no increased hunger, thirst or polyuria. They are said to have had a feeling of well-being and joy of life, in contrast to the regime that marked them out from healthy children. Growth in height and weight, with a few isolated exceptions, were well within the normal limits for healthy children in Sweden. No difficulties were encountered during puberty. As regards the carbohydrate metabolism, the presence of sugar in the urine up to some tens of grams of sugar for twenty-four hours was not considered a cause for concern provided that the patients felt well, and showed no increase in hunger or thirst, polyuria or itch. As a rule, the degree of glycosuria was less than 10 per cent of the carbohydrate intake. As a result of these measures, severe attacks of hypoglycemia were, in fact, extremely rare.

The blood-sugar fasting values in most well controlled cases ranged between 100 and 200 mg per 100 cc.

Lichtenstein believes that the patients reacted better to infections than they did on the previously restricted diets. There was only 1 death from miliary tuberculosis, and of 41 patients who sooner or later

showed a positive tuberculin reaction, only 1 developed a lung focus, and this healed. Neither increase in blood pressure nor demonstrable calcification of the blood vessels was observed. The cholesterol, as a rule, was below 230 mg per 100 cc. In 1 case there was a slight unilateral cataract, and in a number of cases there was a slight transient enlargement of the liver.

Lichtenstein's mortality was low. Of the 169 patients, only 8 died. One was murdered, 1 succumbed to miliary tuberculosis with meningitis a few months after the onset of diabetes, 1 died of pleural empyema with peritonitis and one of scarlet fever, 1 died of oral infection, and 3 died of coma. The mortality rate for the ten-year period was 4.7 per cent. Lichtenstein compares this rate with that of my cases, as reported by White,⁵⁰ which was 8 per cent for 150 cases of fifteen years' duration. A comparison to be valuable should be made between children with similar durations of diabetes. It should be added that the mortality of this clinic will be still higher in the 249 cases that are of twenty years' duration and are soon to be reported.

Hagedorn's protamine insulin was used in Lichtenstein's cases instead of protamine zinc insulin. The dosage varied between 10 and 120 units a day, the average being about 40 units. The maximum dose of regular insulin averaged about 60 units. Lichtenstein also frankly points out:

To obtain good results, one must exercise a careful, continuous control, with at first frequent and gradually more occasional examinations. In the case of children, the control involves good co-operation with the homes, especially with the mothers. It is therefore necessary to give instructions to the mothers. They must learn the principal features in the clinical treatment of the disease, they must learn to recognize, in particular, such changes in the child's condition as require a modification of the insulin dosage, and they must learn to use the insulin syringe correctly. Many mothers in our Swedish clientele can be taught to make qualitative and sometimes also quantitative sugar tests and even to perform Gerhard's and Legal's tests for ketone bodies in the urine. A more important matter, however, is to draw their attention to the significance of *greater thirst* and *large amounts of urine* as indications of unsatisfactory adjustment, and to the importance of immediately getting in touch in such cases with the doctor treating the case. Another important matter is to get the mothers to understand the *signs of hypoglycemia* and how it is counteracted. The importance of a *regular conduct of life* with regular meals should also be strongly emphasized.

My own aversion to the treatment advocated by Lichtenstein arises not so much from the actual diets that he employs — which, as a matter of fact, differ little from the average diet now generally given to diabetic children — as from the psychological effect on the children and the parents of growing up with the belief that their diabetes can be controlled by insulin and not by diet, insulin and exercise. It is the old, old story — a compromise with evil that a possible good may come. Seneca wrote, "We may lay it down as an invariable axiom in all high education that it is never sensible to permit what is bad for the supposed sake of preventing what is worse." In the education of his pupil Nero,

so good a man as Seneca adopted this course but the world knows with what disastrous results. There is unanimous belief among my group that the children who have been treated with great care on a diet including 150 to 200 gm of carbohydrate and who have endeavored to control their diabetes are the ones who have done the best and have avoided the most complications. I know—and my colleagues agree with me—that the patients who have lived on free diets but have admittedly tried less earnestly to control themselves with insulin have been the ones most frequently admitted to the hospital for coma and hypoglycemia. The extremes of such cases will not be included in our twenty-year group, soon to be reported, because these patients are already dead—they did not live even for twenty years.

Long ago I found on visits to noted diabetic clinics in this and other countries that the physicians in charge were skilled clinicians and treated their patients individually and with good results. These clinicians might advocate particular methods of treatment, but in their own clinics they were alive to the individualization of the patient and adjusted the diet and the giving of insulin accordingly. I suspect that this is the case with Lichtenstein, but I also believe that, if he should visit our diabetic camp for girls, he would be impressed with the joyous natures of the campers and would find that they were being given prescribed diets not so very different from those served in their homes by the mothers of his own children, for his intelligent Swedish mothers undoubtedly found that restricted diets worked the best.

STATISTICS ON DIABETES IN FINLAND

The Vartiainens⁵¹ estimated the number of diabetic patients in Finland and at the same time noted the variations in distribution according to age, sex and place of residence—urban or rural. They reached the conclusion that in 1942 the number of such patients was 5800, or 1.6 per 1000 of the total population, which is reported as 3,637,354. If this estimate were applied to the United States, it would mean less than 250,000 such patients. The Vartiainens' estimate is actually based largely on the number of persons receiving aid on account of diabetes, but it is rendered incomplete by the fact that a certain percentage of the inquiries remained unanswered, and by the fact that a large percentage of persons living in the country districts do not require aid of this sort. Without allowing for incomplete replies, chiefly in the urban districts, the Vartiainens reached an estimate of 2703 diabetic patients, but decided that a more nearly correct figure would be 2834. Adding to this number those whose occupations were on farms and in fisheries, they increased their estimate to the final one of 5800.

At the First University Medical Clinic in Helsinki the yearly number of cases treated varied widely,

reaching a peak in the five-year period 1930-1935 and suffering a marked drop in the ensuing five years. They evaluated this variation as partly indicative of the interest of physicians or the preferential admission of patients to the hospital, because in the Second University Medical Clinic the figures were dissimilar.

Comparison of the diabetic mortality computed by insurance companies in Finland with the total mortality of the country gave the surprising result that the percentage of diabetic deaths remained practically constant at 1 per cent from 1890 to 1940, showing only an insignificant drop in the last five years of this period. Information from this source should probably be disregarded, since even in our country it is apparently not considered of great value.

The total diabetic mortality in Finland from 1927 to 1941 showed a steady increase. The number of deaths among males remained nearly stationary, but that among females nearly doubled, the deaths being confined chiefly to patients fifty years of age or above.

The estimated figure of 5800 diabetic patients in Finland, or 1.6 per 1000 population (1 patient among 667 persons), is far lower than the generally accepted incidence in the United States, which is at least 1 patient among 150 inhabitants. Perhaps the methods of computing mortality statistics in the two countries are different. It is said that in 1936 nearly 12 per cent of all deaths in Finland were ascribed to senility and an additional 2 per cent to unknown causes. Moreover, the mortality from tuberculosis was twenty-five times as high as that from diabetes. Some diabetic patients may have been in such groups and thus not included in the estimate.

DIABETIC ASSOCIATIONS, SOCIETIES, FOUNDATIONS AND TRUSTS

Compared with tuberculosis and cancer, diabetes is far behind in the support that it receives from associations, societies, foundations and trusts, yet the need for such support is manifest. There are certainly close to 1,000,000 living diabetic patients in the United States today. Diabetes ranks eighth in the causes of death, and in 1940 it was responsible for 1 death in every 40. Tuberculosis is decreasing, but diabetes is increasing, owing to the prolongation of life in the general population to the age at which the onset of diabetes is most frequent, and owing to the longer duration of life of such patients. One often speaks of childhood diabetes, forgetting that four or more times the life of the diabetic patient with onset in childhood will be lived as an adult.

Centers are needed for experimental investigation, the conducting of statistical studies and the stimulation of physicians in the surrounding communities. Emergency diabetic stations are needed in all large hospitals, hospitals must be properly equipped, and communities must be protected by an

extension of education in the treatment of the disease through hospital classes and outpatient departments. Above all, laboratory facilities must be extended to the practicing physician, because it is he who sees and treats most of the diabetic patients.

The Diabetic Association was inaugurated in London in 1934. The number of members has steadily grown to a total of 8400. Under the auspices of the association *The Diabetic Journal*, now in its fourth year, is issued every three months at the price of 1 shilling an issue. The Diabetic Association thus far is particularly a lay organization, conducted for the benefit of diabetic patients. During the war period it exerted much influence and was of great value to the country in bringing about the system of identification cards for diabetic patients, securing proper rations, making provision for such patients who were rendered homeless and helping to provide a home for diabetic children. It has issued a diabetic cookbook, presents occasional broadcasts on the radio, and is now interested in establishing a Banting Memorial Home. The honorary president is the noted author, H. G. Wells. The driving force among the medical profession has been Dr. R. D. Lawrence.

One of the earliest foundations for diabetes in the United States was the George S. Cox Medical Research Institute, established in 1931 at the University of Pennsylvania in Philadelphia. It is in the Hospital of the University of Pennsylvania, within the Department of Medicine. Dr. C. N. H. Long became the first director in 1932 and served until 1936. He was succeeded by Dr. F. D. W. Lukens, who has served from 1936 to the present time. The staff, in addition to its research work, conducts the outpatient section for diabetes of the Medical Clinic. The laboratory has contributed studies on the physiology and pathogenesis of diabetes. In the clinic, studies on immunity and of the value of exercise and other clinical observations have been made.

For eight years, — from 1934 through 1942, the children of the clinic were sent to the University Camps at Green Lane, where they were supervised by the staff with the assistance of specially trained medical students. This valuable activity was interrupted by the war but will be resumed as soon as possible.

The Renziehausen Foundation was opened on January 1, 1938, in the Children's Hospital of Pittsburgh. It was established through a gift from Miss Emily Renziehausen, of Pittsburgh, for the purpose of taking care of diabetic children. These patients are admitted without charge and are kept under continuous medical and educational supervision up to the age of sixteen. Connected with this foundation is a convalescent home at Large, Pennsylvania, to which children can be sent during the warmer months of the year. The staff of the foundation is made up of members of the faculty

of the Medical School of the University of Pittsburgh and of nurses who are specially trained in pediatrics and diabetic work. Also, the Renziehausen Ward is used for the teaching of medical students and social-service workers. Both the children and parents are taught to know as much about diabetes as possible, and home conditions requiring improvement are usually corrected. Patients are accepted regardless of race, color, creed or financial status, up to the capacity of the foundation to give them proper care.

The New York Diabetes Association was established in New York City in 1934 through the efforts of Drs. Charles Bolduan and Herman O. Mosenthal, with the financial aid and the endorsement of Lucius Littauer. It was affiliated with the New York Tuberculosis and Health Association for three years, and then became independent, with offices at the New York Academy of Medicine. Drs. Herman O. Mosenthal, James Ralph Scott, Charles F. Bolduan, George E. Anderson and Frederick W. Williams have successively been presidents of the association.

The activities of the association have included the publication of *Fundamental Concepts*, which are pamphlets on various phases of diabetes. These have been widely distributed to the profession and to medical schools. A children's camp has been conducted since 1936. At first, the camp accommodated 30 children for a two-week period each. In the summer of 1945, 100 children were taken for a period of four weeks, each, and for 1946 a permanent site, with buildings accommodating approximately 250 children during the summer, has been acquired.

Research projects have been established during the last eight years, and numerous publications have resulted from them. Scientific meetings for physicians and lectures for the laity have been successfully carried out. The latest project of the New York Diabetes Association has been to found the Clinical Society of the New York Diabetes Association. This has secured a large membership among the physicians of Greater New York. This society holds meetings for physicians, is certifying specialists in diabetes in its area, and is taking steps for the standardization of diabetic clinics.

In Cincinnati in 1935, an organization for diabetes was begun. It was established under the name of the Council on Diabetes of the Public Health Foundation. It has led an active existence. Statistical studies have been made, public meetings have been held from time to time, and special posters and exhibits have been prepared and distributed. In 1939, a diabetes instruction service was inaugurated for the benefit of physicians who had the care of diabetic patients in the low income group. Refresher courses for nurses and physicians were established, and a radio program on diabetes was presented in a Sunday evening series. Letters sug-

gesting the possibility of employment of controlled diabetic patients were sent to the directors of industries. Diabetic identification cards were distributed, and a camp was operated for children. At one time an inventory of diabetes in the local schools was made, with the result that a sample survey of 5800 children disclosed only 3 diabetic children, thus indicating a number too small to warrant such an extension of the project to the entire school system.

The American Diabetes Association may be said to have been an outgrowth of the Cincinnati society. Dr. Cecil Striker, of Cincinnati, served as its first president and continues to be its efficient activating force. The first annual meeting was held in June, 1941, but the constitution of the association was adopted on June 12, 1940. Yearly meetings have been held, and the reports of the association's activities and papers read have been published. A notable contribution to the control of diabetes throughout the world has been the issuance of *Diabetes Abstracts*. This quarterly is published by the association and is financed with the help of the Eli Lilly Company. It contains abstracts of all articles on diabetes appearing in medical journals throughout the world. The membership of the association now exceeds 750.

The Philadelphia Metabolic Association was organized in 1934 by a group of physicians particularly interested in diabetes, composed mostly of the chiefs of various diabetic clinics in Philadelphia and their assistants. The association met monthly at different hospitals, at which time cases of interest were discussed. The association became interested in the broader aspect of the treatment of diabetes and admitted to membership social workers, nurses and dietitians whose chief interest was in this disease. It held several public meetings and organized and conducted for three years a summer camp for diabetic children. Lay interest in the diabetic problem increased steadily among public-spirited individuals, many of them outstanding citizens of Philadelphia who had diabetes. It was believed that more could be accomplished if the organization were incorporated, and this was done in 1940. At that time it was thought that the association could do a great deal more if the officers were lay people and the physicians acted in an advisory capacity.

The enlarged association conducted a much bigger camp for children during the summers of 1939, 1940 and 1941. The John B. Deaver Memorial Auxiliary became interested in the project and shared half its financing with the Philadelphia Metabolic Association. Children were admitted from clinics in Philadelphia, as well as some patients in the low-income group referred by private physicians. There were also patients from as far away as Maryland and New Jersey. These three camps had a completely adequate staff of a resident physician, two nurses, a technician and a dietitian,

in addition to the usual camp personnel. Because of inability to obtain adequate personnel, the camps have been abandoned since the war.

The Association sponsored a series of newspaper articles on diabetes by a feature reporter. These articles discussed the disease and the rationale of its treatment and described the advantages to be expected from satisfactory diabetic control. They appeared each day for one week in the *Philadelphia Inquirer*, and it is believed that they did a great deal to increase lay knowledge concerning diabetes. The Association publishes quarterly the *Diabetic Digest*, which is somewhat similar to but smaller than the organ of the British association. This publication is written for the lay diabetic patient and is sent to all association members and other interested persons and groups. During the war the Association first began the distribution of identification cards to diabetic patients, and this work is continuing. An attempt was also made to improve the employment conditions of these patients.

The association at present has about 500 members, over 80 per cent of whom are diabetic patients, the remainder being physicians and other professional people.

The Diabetic Commission of the Pennsylvania Medical Society was organized ten years ago and is composed of a chairman, appointed by the president of the state society, and a representative of each councilor district in the society. In addition, under the commission's general guidance, each county society has a diabetic committee whose function it is to stimulate interest in diabetes and to see that a sufficient number of the society's meetings are devoted to this disease. Under the stimulus of the commission and its county chairmen, more than one hundred and thirty-five meetings of the county societies and their sub-branches were devoted to diabetes during 1942. The commission published the *Primer on Diabetes*, which was distributed to more than 3000 members of the state society and other interested persons. A second edition is being printed. The commission also prepared a motion picture on diabetes, which was suitable for lay groups, and this too had a wide circulation. During the war the commission supplied identification disks, as well as identification cards, to diabetic patients in the state. Under the auspices of a subcommittee in Philadelphia, a survey has been made of all death certificates on which the word "diabetes" appeared. The commission had an exhibit on diabetes at three meetings of the state society, and in conjunction with these concluded a series of talks, which were well attended.

The commission and the Philadelphia Metabolic Association are co-operating with the Philadelphia Tuberculosis Association in making a routine chest-plate examination of all diabetic patients in the city. Diabetic organizations exist in Washington. The Diabetic Trust Fund of the State of Washington

as officially incorporated under the nonprofit corporation laws of the state in 1940, but had its actual beginning in 1924. In that year, \$1000 was given to Dr. Lester J. Palmer to be used for the welfare of diabetic patients, and at my suggestion this money was employed to establish a small store at the Virginia Mason Hospital to dispense diabetic supplies. This store is still a valuable source of income for the fund. As funds accumulated, they were held in trust by the Virginia Mason Hospital until 1940, when the Diabetic Trust Fund was established as a separate organization. In 1945, the fund represented about \$30,000. Its growth is being aided by voluntary contributions, mostly small ones, by the net income of the diabetic store and by a modest annual spring drive, carried on each year chiefly for the purpose of financing the summer camps. The fund at present supports two projects — the publishing of *The Diabetic Monthly* and the financing of the summer camps.

The Washington Diabetes Association, a council of physicians interested in diabetes, was organized in May, 1942, but no further meetings were held because of the war. The next regular meeting is about to take place. About 300 diabetic patients have paid dues. The objectives of this body, as set forth in its constitution and bylaws, are similar to those of the American Diabetes Association. It is closely affiliated with the Diabetic Trust Fund.

Camp Banting for Diabetic Boys held its first session in the State of Washington, in 1938, and the Priscilla White Camp for diabetic girls in the same state in 1939. Annual sessions of two weeks each have since been held. These camps are conducted on the property of the Boy Scouts of America and the Camp Fire Girls. Plans are in progress to construct an independent camp building at these camps. Some children are taken free and others on part pay or full pay. The annual attendance at both camps averages 35 to 40 boys and girls.

For a good many years in Boston, a group of physicians from a dozen or more of the principal hospitals have met yearly and discussed problems of diabetic interest. No formal society has been established, but this subject is under consideration. The group has been sponsored to a considerable extent by the Massachusetts Tuberculosis League and has often had the advantage of the attendance of state or city officials from their respective departments of health.

A diabetic camp, established by physicians in Boston, has been in existence since 1927. It is the second one in the country, the first having been that of Dr. and Mrs. Wendt in Detroit. Fortunately, during the last fourteen years the Association of Universalist Women has placed at the camp's disposal the grounds and buildings of the Clara Barton Homestead in North Oxford, Massachusetts. In addition, the members of this body have materially enlarged and improved the equipment each year.

In the last twelve months, the Clara Barton Homestead Camp accommodated four sets of diabetic girls in groups of 50, each group being taken for a two-week period. Many of these children remained for more than two weeks, however, so that actually only 123 children had the benefit of the camp. Its total expense was approximately \$10,000, of which the children voluntarily contributed about half. Each year diabetic girls are offered an opportunity to go to the camp, and preference is given to those who can make no payments or only small, voluntary ones. The balance of the expense has been largely borne by the Association of Universalist Women, the friends of physicians of the George F. Baker Clinic of the New England Deaconess Hospital, and the Diabetic Fund.

The Diabetic Fund was inaugurated at the Boston Safe Deposit and Trust Company on February 2, 1944. It was established in this trust company because of its particular interest in the Charity Fund and its experience with it. Sums given to the Diabetic Fund are held in trust by the trust company, and the income or a limited part of the principal is available for promotion of diabetic research and diabetic activities under the supervision of an advisory committee. This committee consists of a representative appointed every seven years by the dean of the Tufts College Medical School, one similarly appointed by the dean of the Harvard Medical School and five others associated with the George F. Baker Clinic of the New England Deaconess Hospital. This endowment has grown, and by November 21, 1945, it had received \$93,102.18 in gifts and pledges and had disbursed \$15,000. A friend of the undertaking, desiring that only the income of his donation should be used, established along the same lines, with the same advisory committee, the Horace E. Munroe Permanent Diabetic Fund as a component of the Permanent Diabetic Fund, and these permanent funds have together reached \$7877. Thus far grants have been made, particularly because of the expressed wish of the donors, for research in alloxan and diabetic pregnancies. In addition, allotments have been made for children in diabetic camps and for a grant to the American Diabetes Association.

Finally, a special endeavor has been made in connection with the present building-fund campaign at the New England Deaconess Hospital to secure funds for 50 new diabetic beds and other diabetic projects, among which is a coma unit. Gifts have been sought from a multitude of patients, with the idea that \$1 received from 1000 different patients would accomplish far more than \$1000 from one, because in the former case there would be driven home to many patients the need for research and improvement in the care of such patients, and incidentally make them realize the desirability of animal experimentation. Patients and friends of the New England Deaconess Hospital have re-

gesting the possibility of employment of controlled diabetic patients were sent to the directors of industries. Diabetic identification cards were distributed, and a camp was operated for children. At one time an inventory of diabetes in the local schools was made, with the result that a sample survey of 5800 children disclosed only 3 diabetic children, thus indicating a number too small to warrant such an extension of the project to the entire school system.

The American Diabetes Association may be said to have been an outgrowth of the Cincinnati society. Dr. Cecil Striker, of Cincinnati, served as its first president and continues to be its efficient activating force. The first annual meeting was held in June, 1941, but the constitution of the association was adopted on June 12, 1940. Yearly meetings have been held, and the reports of the association's activities and papers read have been published. A notable contribution to the control of diabetes throughout the world has been the issuance of *Diabetes Abstracts*. This quarterly is published by the association and is financed with the help of the Eli Lilly Company. It contains abstracts of all articles on diabetes appearing in medical journals throughout the world. The membership of the association now exceeds 750.

The Philadelphia Metabolic Association was organized in 1934 by a group of physicians particularly interested in diabetes, composed mostly of the chiefs of various diabetic clinics in Philadelphia and their assistants. The association met monthly at different hospitals, at which time cases of interest were discussed. The association became interested in the broader aspect of the treatment of diabetes and admitted to membership social workers, nurses and dietitians whose chief interest was in this disease. It held several public meetings and organized and conducted for three years a summer camp for diabetic children. Lay interest in the diabetic problem increased steadily among public-spirited individuals, many of them outstanding citizens of Philadelphia who had diabetes. It was believed that more could be accomplished if the organization were incorporated, and this was done in 1940. At that time it was thought that the association could do a great deal more if the officers were lay people and the physicians acted in an advisory capacity.

The enlarged association conducted a much bigger camp for children during the summers of 1939, 1940 and 1941. The John B. Deaver Memorial Auxiliary became interested in the project and shared half its financing with the Philadelphia Metabolic Association. Children were admitted from clinics in Philadelphia, as well as some patients in the low-income group referred by private physicians. There were also patients from as far away as Maryland and New Jersey. These three camps had a completely adequate staff of a resident physician, two nurses, a technician and a dietitian,

in addition to the usual camp personnel. Because of inability to obtain adequate personnel, the camps have been abandoned since the war.

The Association sponsored a series of newspaper articles on diabetes by a feature reporter. These articles discussed the disease and the rationale of its treatment and described the advantages to be expected from satisfactory diabetic control. They appeared each day for one week in the *Philadelphia Inquirer*, and it is believed that they did a great deal to increase lay knowledge concerning diabetes. The Association publishes quarterly the *Diabetic Digest*, which is somewhat similar to but smaller than the organ of the British association. This publication is written for the lay diabetic patient and is sent to all association members and other interested persons and groups. During the war the Association first began the distribution of identification cards to diabetic patients, and this work is continuing. An attempt was also made to improve the employment conditions of these patients.

The association at present has about 500 members, over 80 per cent of whom are diabetic patients, the remainder being physicians and other professional people.

The Diabetic Commission of the Pennsylvania Medical Society was organized ten years ago and is composed of a chairman, appointed by the president of the state society, and a representative of each councilor district in the society. In addition, under the commission's general guidance, each county society has a diabetic committee whose function it is to stimulate interest in diabetes and to see that a sufficient number of the society's meetings are devoted to this disease. Under the stimulus of the commission and its county chairmen, more than one hundred and thirty-five meetings of the county societies and their sub-branches were devoted to diabetes during 1942. The commission published the *Primer on Diabetes*, which was distributed to more than 3000 members of the state society and other interested persons. A second edition is being printed. The commission also prepared a motion picture on diabetes, which was suitable for lay groups, and this too had a wide circulation. During the war the commission supplied identification disks, as well as identification cards, to diabetic patients in the state. Under the auspices of a sub-committee in Philadelphia, a survey has been made of all death certificates on which the word "diabetes" appeared. The commission had an exhibit on diabetes at three meetings of the state society, and in conjunction with these concluded a series of talks, which were well attended.

The commission and the Philadelphia Metabolic Association are co-operating with the Philadelphia Tuberculosis Association in making a routine chest-plate examination of all diabetic patients in the city.

Diabetic organizations exist in Washington. The Diabetic Trust Fund of the State of Washington

was officially incorporated under the nonprofit corporation laws of the state in 1940, but had its actual beginning in 1924. In that year, \$1000 was given to Dr. Lester J. Palmer to be used for the welfare of diabetic patients, and at my suggestion this money was employed to establish a small store at the Virginia Mason Hospital to dispense diabetic supplies. This store is still a valuable source of income for the fund. As funds accumulated, they were held in trust by the Virginia Mason Hospital until 1940, when the Diabetic Trust Fund was established as a separate organization. In 1945, the fund represented about \$30,000. Its growth is being aided by voluntary contributions, mostly small ones, by the net income of the diabetic store and by a modest annual spring drive, carried on each year chiefly for the purpose of financing the summer camps. The fund at present supports two projects — the publishing of *The Diabetic Monthly* and the financing of the summer camps.

The Washington Diabetes Association, a council of physicians interested in diabetes, was organized in May, 1942, but no further meetings were held because of the war. The next regular meeting is about to take place. About 300 diabetic patients have paid dues. The objectives of this body, as set forth in its constitution and bylaws, are similar to those of the American Diabetes Association. It is closely affiliated with the Diabetic Trust Fund.

Camp Banting for Diabetic Boys held its first session in the State of Washington, in 1938, and the Priscilla White Camp for diabetic girls in the same state in 1939. Annual sessions of two weeks each have since been held. These camps are conducted on the property of the Boy Scouts of America and the Camp Fire Girls. Plans are in progress to construct an independent camp building at these camps. Some children are taken free and others on part pay or full pay. The annual attendance at both camps averages 35 to 40 boys and girls.

For a good many years in Boston, a group of physicians from a dozen or more of the principal hospitals have met yearly and discussed problems of diabetic interest. No formal society has been established, but this subject is under consideration. The group has been sponsored to a considerable extent by the Massachusetts Tuberculosis League and has often had the advantage of the attendance of state or city officials from their respective departments of health.

A diabetic camp, established by physicians in Boston, has been in existence since 1927. It is the second one in the country, the first having been that of Dr. and Mrs. Wendt in Detroit. Fortunately, during the last fourteen years the Association of Universalist Women has placed at the camp's disposal the grounds and buildings of the Clara Barton Homestead in North Oxford, Massachusetts. In addition, the members of this body have materially enlarged and improved the equipment each year.

In the last twelve months, the Clara Barton Homestead Camp accommodated four sets of diabetic girls in groups of 50, each group being taken for a two-week period. Many of these children remained for more than two weeks, however, so that actually only 123 children had the benefit of the camp. Its total expense was approximately \$10,000, of which the children voluntarily contributed about half. Each year diabetic girls are offered an opportunity to go to the camp, and preference is given to those who can make no payments or only small, voluntary ones. The balance of the expense has been largely borne by the Association of Universalist Women, the friends of physicians of the George F. Baker Clinic of the New England Deaconess Hospital, and the Diabetic Fund.

The Diabetic Fund was inaugurated at the Boston Safe Deposit and Trust Company on February 2, 1944. It was established in this trust company because of its particular interest in the Charity Fund and its experience with it. Sums given to the Diabetic Fund are held in trust by the trust company, and the income or a limited part of the principal is available for promotion of diabetic research and diabetic activities under the supervision of an advisory committee. This committee consists of a representative appointed every seven years by the dean of the Tufts College Medical School, one similarly appointed by the dean of the Harvard Medical School and five others associated with the George F. Baker Clinic of the New England Deaconess Hospital. This endowment has grown, and by November 21, 1945, it had received \$93,102.18 in gifts and pledges and had disbursed \$15,000. A friend of the undertaking, desiring that only the income of his donation should be used, established along the same lines, with the same advisory committee, the Horace E. Munroe Permanent Diabetic Fund as a component of the Permanent Diabetic Fund, and these permanent funds have together reached \$7877. Thus far grants have been made, particularly because of the expressed wish of the donors, for research in alloxan and diabetic pregnancies. In addition, allotments have been made for children in diabetic camps and for a grant to the American Diabetes Association.

Finally, a special endeavor has been made in connection with the present building-fund campaign at the New England Deaconess Hospital to secure funds for 50 new diabetic beds and other diabetic projects, among which is a coma unit. Gifts have been sought from a multitude of patients, with the idea that \$1 received from 1000 different patients would accomplish far more than \$1000 from one, because in the former case there would be driven home to many patients the need for research and improvement in the care of such patients, and incidentally make them realize the desirability of animal experimentation. Patients and friends of the New England Deaconess Hospital have re-

sponded generously to solicitation, and at the present moment \$243,000 has been received from 3112 persons for extension of the facilities of the hospital along diabetic lines. It seems particularly desirable that this plan of securing gifts from the many and not from the few should be cultivated, and it is the hope of those inaugurating the diabetic funds at the Boston Safe Deposit and Trust Company and the diabetic projects at the New England Deaconess Hospital that the example set will be followed in other localities.

It is a sign of the increasing interest in and importance of diabetes that in the plans for the addition to the Rhode Island Hospital in Providence \$54,000 has been set aside for the Diabetes Clinic.

Active work in diabetes is in progress in a multitude of hospitals and laboratories. I hesitate to publish the above list of societies, but do so partly with the idea that this will lead to corrections and

amplifications, which I shall receive with gratitude. At the Mayo Clinic, in St. Louis, in Omaha, Nebraska, at the University of California and in various hospitals in Chicago extremely active diabetic investigation is going on. Diabetic camps have been conducted at various times in connection with work in the above localities, and continuously at the University of California since 1938. I understand that a diabetic trust fund is in process of creation in Portland, Oregon, and that an organization of somewhat wider scope is being formed in Omaha.

CASE 32141

PRESENTATION OF CASE

A sixty-year-old housewife was admitted to the hospital because of jaundice.

A year and a half before admission the patient became weak and lethargic and had mild anorexia. She remained in bed for several weeks and slowly regained strength until four months before admission, when she became insidiously tired and was noted to have jaundice. Her skin itched slightly, and her urine became dark. Her appetite disappeared. At the height of the jaundice a Graham-Cole test was unsuccessfully attempted by her physician. On a low-fat, low-calorie diet the jaundice slowly disappeared, but it recurred one month before admission. At that time she had two episodes a week apart of sudden acute colicky pain in the right upper quadrant. Each attack lasted half an hour and was not associated with nausea or vomiting. She had had no chills or fever at any time. During that month she was given iron and liver for anemia. The iron was stopped four days prior to

admission, and after that her stools were clay colored. The color of the stools had not been observed previously. There had been a 25-pound weight loss in the four months prior to admission. There had been no swelling of the abdomen or ankles at any time.

The patient had been jaundiced as a child. Seven years before admission an appendectomy had been performed. Prior to the onset of jaundice it was routine for the patient to have one or two cocktails before lunch and dinner and a highball at bedtime. Thereafter her appetite for alcohol decreased proportionately with her desire for food so that she had only an occasional cocktail at noon.

On physical examination the patient was thin and sallow, with a yellowish-brown skin and yellow scleras. There were Grade I apical and aortic systolic murmurs. The liver was palpable in the right hypochondrium and in the epigastrium, the edge was tender and round and the surface was questionably nodular. The tip of the spleen was palpable. There was a firm round mass in the right upper quadrant, immediately beneath the liver edge.

The temperature was 98.6°F, the pulse 75, and the respirations 20. The blood pressure was 132 systolic, 76 diastolic.

The hemoglobin was 12.8 gm. The white-cell count was 8800, with 59 per cent neutrophils, 28 per cent lymphocytes, 7 per cent monocytes and 6 per cent eosinophils. The urine had a specific gravity of 1.028 and gave a ++ test for albumin and a +++ test for bile. The sediment contained 25 white cells and 10 epithelial cells per high-power field. The test for urobilinogen was positive in a dilution of 1:100. The prothrombin time was 30 seconds (normal, 18 seconds), and the serum protein 6.7 gm, with an albumin globulin ratio of 2:1.

The nonprotein nitrogen was 29 mg per 100 cc, and the alkaline phosphatase 26.7 Bodansky units. The stools varied from brown to clay colored and from strongly to slightly positive for bile, they were guaiac negative. During the Graham test the gall bladder contained poorly concentrated dye and was not well visualized, it appeared to contract after a fat-containing meal. No stones were seen. Fluoroscopically the stomach contained a questionable filling defect close to the cardia in the lesser curvature. The stomach was long and low in position. The second portion of the duodenum lay considerably more to the right than usual, and there was a suggestion of a filling defect at the junction of the second and third portions. So far as could be demonstrated the duodenal loop and head of the pancreas were readily movable. At the end of six hours the barium was scattered through the terminal ileum and colon.

On the sixth hospital day the patient had an attack of biliary colic and the jaundice increased.

An operation was performed on the eighth hospital day.

DIFFERENTIAL DIAGNOSIS

DR WYMAN RICHARDSON: This is a case of jaundice, and it presents the same old problem of deciding whether it was intrahepatic or obstructive, or both. Let us briefly review the clinical history for a moment. I have no answer for the lethargy and weakness, which were present one and a half years before entry, as part of the present illness. It makes some difference regarding the ultimate diagnosis. The skin itched slightly at the time of admission, and the urine became dark. Although it says "slightly," that may be of some importance, and as you know it suggests biliary obstruction rather than intrahepatic jaundice. At the height of the jaundice the Graham-Cole test was unsatisfactory. I believe that it is usually considered rather pointless to try to visualize the gall bladder by x-ray in the presence of deep jaundice. Is that so, Dr Lingley?

DR JAMES R LINGLEY: Yes.

DR RICHARDSON: The low-fat diet was all right in the presence of jaundice, but I should say that a high-protein, high-carbohydrate, high-calorie diet containing numerous supplementary vitamins was indicated rather than a low-calorie diet. The pain is described as colicky, but it appeared to be of brief duration.

I "saw red" when I read that both iron and liver were given for anemia. This is done frequently, but if the anemia improves, one does not know whether the improvement was due to the giving of liver or to the giving of iron. It is rare that both iron and liver need to be given to the same patient.

"The patient had been jaundiced as a child." I take it that that means an episode of jaundice and not prolonged jaundice throughout childhood. It

could be interpreted as infectious hepatitis, and one may consider that a previous attack of infectious hepatitis may predispose the liver to damage later on. There is some evidence of this fact in a paper published by Dr Altschule and Dr Gilligan.* To me the evidence is not entirely convincing, since it is based on certain tests some of which, it seems to me, are not entirely specific for liver failure.

There is a slight alcoholic aroma to the history. That may be put in to make it difficult to decide about the question of the cause of this jaundice.

The patient had a yellow-brown skin. I do not know the nationality.

DR TRACY B MALLORY: She was Irish.

DR RICHARDSON: The yellow-brown skin is suggestive of biliary obstruction rather than intrahepatic jaundice.

The "questionably nodular" liver leaves me cold. I think that it is extremely difficult to feel a nodular liver through an abdominal wall. One may feel a grossly nodular liver, such as occurs in the hepatic lobatum of syphilis, and with especially big tumor nodules one may get the impression that the liver is irregular, but, as I have said, a questionably nodular liver means nothing to me.

The fact that the tip of the spleen was palpable is of great importance, and if that notation appears on the record one can usually accept it. In other words a positive finding seems to me more important than a negative finding, especially regarding the spleen.

The firm round mass in the upper quadrant could well have been a dilated gall bladder, although it is frequently difficult to feel a gall bladder and sometimes it does not give the impression of being firm.

The 12.8 gm of hemoglobin indicates a slight anemia. It is perhaps a definite one, even though this patient was a woman. The blood differential was normal. I shall assume that the 6 per cent eosinophils was within the normal limits. The urine was essentially normal, except for the fact that bilirubin was being passed through the kidney. There were a few white cells, but I do not believe that they were significant.

Urobilinogen was present in the urine in a dilution of 1:100. That is definitely increased and means, according to my own definition, that bilirubin was excreted into the gut, because as I understand it, urobilinogen is formed from bilirubin only in the gut, it is reabsorbed and excreted normally through the kidney to some degree, but it may be excreted in increased amounts when there is an increased load of bilirubin going through the biliary system. It may also be increased in some cases when there is inability on the part of the liver to excrete urobilinogen, whereas at the same time the liver can excrete bilirubin. That is confusing. The point is that the presence of increased uro-

* Altschule, M. D. and Gilligan, D. R. Chronic latent hepatitis following catarrhal jaundice. *New Eng J Med* 231:315-317, 1944.

bilinogen in the urine should be a great help, but it frequently is not. In this case it is corroborative evidence that bilirubin was being excreted through the biliary tract into the gut.

The prothrombin time was slightly elevated, and the serum protein was normal. The normal albumin-globulin ratio suggests that there was no considerable degree of intrahepatic disease. The alkaline phosphatase was distinctly elevated, which is in favor of biliary obstruction and somewhat in favor of neoplastic disease.

I want to ask Dr. Lingley whether the head of the pancreas ever is movable. I had not supposed that it was.

DR. LINGLEY: I should not expect it to be.

DR. RICHARDSON: I wonder why it said "readily movable."

DR. LINGLEY: I believe that it is a mistake that the examiner meant the duodenum, rather than the pancreas.

DR. RICHARDSON: Is there or is there not a peptic ulcer in the midportion of the duodenum? The report is mildly suggestive. Would you interpret that as being questionable?

DR. LINGLEY: Yes. The second portion of the duodenum is sometimes difficult to examine because you cannot fill it completely. Small lesions may be hard to demonstrate and in this case I judge that there was some question about it in the examiner's mind.

DR. RICHARDSON: Is there any other comment that you would like to make?

DR. LINGLEY: In regard to the gastric filling defect, the left lobe of the liver can push over against the stomach immediately beneath the cardia and produce a pressure defect where this one is described.

DR. RICHARDSON: I think that the evidence is strong that this patient had a biliary obstructive lesion. The question is, Was it a ball-valve effect or was there a partial obstruction that allowed a certain amount of bile to get through but not the normal amount? Can we rule out intrahepatic disease? I do not believe that one can completely rule it out, but it seems to me that the clinical history is opposed to it, except for the use of alcohol. There was no edema, ascites or varices, and the serum protein was normal. The prothrombin time can be elevated in either condition. There is no note whether the prothrombin time returned to normal after the administration of vitamin K₁. If it did, it might be of some value in indicating that this was an obstructive lesion.

What type of lesion was it? I think that in the wards we frequently have a grand guessing match and end up by operating on the patient to find out. I sincerely believe that any patient with biliary obstruction should be operated on, even though the probability of a malignant tumor may be strong. I remember one patient who was not operated on and whom Dr. Mallory finally examined, only to

find a miserable little stone in the mouth of the common bile duct. As between obstruction, tumor and stone, in favor of tumor are the enlarged gall bladder, the considerable increase in the alkaline phosphatase and the appreciable weight loss. In favor of stone is the history of colicky pain, which I think may occur with either condition but is nevertheless suggestive of stone. We are told that in the presence of stone the gall bladder is usually small and not large. The palpable spleen is not much more in favor of stone than it is of malignancy, but it is suggestive of intrahepatic disease.

Finally, should one consider the possibility of a peptic ulcer in the region of the ampulla, which had caused constriction and resulted in an obstructive lesion? That does occur rarely, but I should expect it to occur in a chronic, long-standing ulcer, of which there is a little evidence in this patient.

I cannot think of any other way to narrow this down. I think that this patient had a malignant tumor, probably arising in the pancreas. It is possible that she had both some type of obstructive lesion and intrahepatic disease, but I am not going to complicate matters by saying that. I will say that there was no intrahepatic disease other than that associated with biliary obstruction, a beginning biliary cirrhosis, if you will. I believe that it is more usual to have intermittent jaundice with stone than with tumor, although I think that it does occur with the latter. My final diagnosis is, as I have said, malignant tumor, probably carcinoma of the head of the pancreas.

CLINICAL DIAGNOSIS

Carcinoma of head of pancreas

DR. RICHARDSON'S DIAGNOSIS

Malignant tumor, probably carcinoma, of head of pancreas

ANATOMICAL DIAGNOSIS

Carcinoma of ampulla of Vater

PATHOLOGICAL DISCUSSION

DR. MALLORY: I am sorry that Dr. Chester M. Jones was called away. I had hoped that he would discuss this case. He thought, as Dr. Richardson did, that the probable diagnosis was carcinoma of the head of the pancreas and that the patient deserved exploration. This was carried out and the enlarged gall bladder contained rather light colored bile and quite a bit of gravel-like sediment. The common duct was dilated. An attempt to pass a probe through the ampulla was fruitless, and the surgeon had the impression that with the tip of the probe he could feel a soft tumor mass rather than a stone. Since he was unable to decide from above, he opened the duodenum in order to palpate the ampulla from both sides. On doing that he became convinced that there was a tumor in the ampulla.

He could not make out any extension, and it seemed that it might be possible to resect it. It was not believed, however, that the patient could stand the operation at that time. So the gall bladder was drained and the patient was sent home for a few weeks, to return to the hospital for radical resection. At that time the pyloric antrum of the stomach, the first and second portions of the duodenum and half of the pancreas were resected. The remaining pancreas was sutured into the intestinal wall, and the operative reconstructions were carried out. After a stormy convalescence she was able to leave the hospital in fairly good shape.

The resected specimen showed a small tumor — only about 2 cm in diameter — sharply restricted to the region of the ampulla but extending a little way up the common bile duct and a little way up the pancreatic duct. The mouths of both the bile duct and the pancreatic duct were found in the small ulcerated crater of the tumor. Microscopic examination showed a fairly well differentiated adenocarcinoma. There were numerous enlarged regional lymph nodes, but all of them were free from metastases, and so far as one could judge, the tumor seemed to have been completely removed.

DR RICHARDSON: Did they biopsy the liver?

DR MALLORY: No biopsy specimen was taken. The liver was smooth and moderately bile stained. They thought that it was normal except for the bile stasis, and at the time of the second operation most of that had disappeared.

A PHYSICIAN: Where did you say that the tumor arose?

DR MALLORY: It was a carcinoma of the ampulla of Vater. There are both benign papillomas and malignant carcinomas of the ampulla. I am not sure that in this hospital we have ever seen a benign papilloma, but there are numerous cases on record. One other point worth remembering when the question of operation arises is that it is quite possible to find a benign as well as a malignant neoplastic obstruction, if the patient can be suitably prepared for operation, it is well worth the risk to attempt resection.

CASE 32142

PRESENTATION OF CASE

First admission. A thirty-four-year-old Irishman entered the hospital because of severe pain in the epigastrium and left flank of four days' duration.

Five years before entry he first began to suffer from gnawing, burning nonradiating pain in the epigastrium following meals by one or two hours and usually relieved by food or sodium bicarbonate. These attacks had been cyclic in nature, with two-month to three-month periods of postprandial pain alternating with four-month to five-month periods of freedom from symptoms. Prior to entry he had had severe postprandial epigastric distress for three

weeks, gradually becoming worse and only partially relieved by food and alkali. On two occasions he vomited recently ingested food without gross blood. In addition to the epigastric distress he developed pain in the left groin that radiated to the flank and back.

Physical examination was negative except for a soft apical systolic murmur. The blood pressure was 140 systolic, 85 diastolic. The laboratory studies were essentially negative. A barium meal disclosed a constantly irregular duodenal cap with a fleck of barium in its lower portion.

After three weeks in the hospital the patient was discharged to be followed in the Out Patient Department.

Second admission (thirteen years later). During the interval the patient continued to have epigastric pain but refused to follow the dietary regimen described. He was, however, able to continue his work. The morning of re-admission he left home for work feeling well, but suddenly he was doubled up by an excruciating midline stabbing abdominal pain that spread to the umbilicus. This pain remained constant.

On physical examination the patient was a well developed and well nourished pale perspiring man in acute abdominal distress. The neck and chest were negative. The abdomen was tense with generalized spasm, most marked in the epigastrium. There was generalized tenderness, peristalsis was absent.

The temperature was 99°F, the pulse 112, and the respirations 40. The blood pressure was 170 systolic, 90 diastolic.

The white-cell count was 14,000, with 87 per cent neutrophils. The urine was normal.

The patient was taken to the operating room, and abdominal exploration was done. The duodenum was found to be heavily scarred, and there was a perforated duodenal ulcer, which was closed by sutures.

After the operation the patient was improved but continued to have epigastric pain and to run a temperature of 100°F. Two days later his condition suddenly became worse. He complained of severe, constant epigastric pain that occasionally radiated into the right groin. There was no vomiting. Morphine failed to bring relief. The blood pressure was 150 systolic, 90 diastolic. The abdomen was board-like, with tenderness and rebound pain, peristalsis was absent. He was prepared for operation, but after induction of anesthesia, his color suddenly became poor, his respirations shallow, and his pulse imperceptible. Despite all resuscitative measures the patient went downhill rapidly and died.

DIFFERENTIAL DIAGNOSIS

DR HOWARD ULFELDER: This patient, in brief, was a man of forty-seven with duodenal ulcer of

eighteen years' standing. No other organic lesion is described, nor does the history suggest that any was suspected.

The last admission was precipitated by perforation into the free peritoneal cavity. This was treated in orthodox surgical fashion, but the immediate postoperative course was marred by persistent fever and epigastric pain. On the second day there was a sharp turn for the worse. This complication was obviously considered amenable to surgical correction, but with the induction of anesthesia the patient took another sharp downward turn and soon expired.

Could this have been a pure anesthetic death? If so, one must still speculate on the nature of the complication that necessitated return to the operating room. It appears more plausible to me to assume that the burden of anesthesia alone was more than this patient could stand, his compensatory mechanisms had already been called on, and his reserves were spent. This view is supported by the fact that anesthesia precipitated a state of profound circulatory collapse. Although the possibility of asphyxia secondary to laryngospasm or aspirated gastric contents should be mentioned, the account of this man's terminal moments does not fit this diagnosis.

Turning now to the mishap that occurred on the second postoperative day, one can suspect that it was due either to a vascular accident or to peritonitis. The past history gives me no leads, although there is mention of pain in the left groin and flank at the time of the first hospital admission and in the right groin on the day of death. The former I shall ascribe to an unusual but not unheard of radiation from the upper gastrointestinal tract. The latter is easily explained by the presence of irritating or infected fluid in the right gutter.

Among vascular accidents, only mesenteric thrombosis deserves attention. Some evidence of obstruction usually accompanies this lesion. None is described here. Coronary occlusion, dissecting aneurysm and pulmonary embolism fail to fit either the symptoms or the physical findings.

Under the heading of peritonitis, mention must be made of a perforated gall bladder, appendix and bowel and of acute pancreatitis. None of these can be completely excluded, but all appear extremely unlikely.

Three lesions remain for serious consideration. Leakage at the site of the recent duodenal suture appears the likeliest, but according to the literature this is extremely rare. Rupture of a previously localized abscess would not be expected so soon after the primary insult. My diagnosis is perforation of a separate peptic ulcer. This also is infrequent,

but ulcers are notoriously multiple during periods of activity and one example of this coincidence was noted in a review of 334 cases of benign perforated ulcer observed in this hospital.*

I predict, therefore, that post-mortem examination revealed early generalized peritonitis, recent duodenal perforation with intact closure, and a separate ulcer (probably gastric), with perforation into the free peritoneal cavity.

DR RODOLFO E. HERRERA When the patient was taken to the operating room the second time, it was our feeling that we were compelled to rule out a leak from the site of the previous perforation or from a new site. Although the patient had complained of pain almost constantly after recovery from his first anesthesia, his condition appeared good, there was, however, a definite exacerbation of pain on the second postoperative day. At that time an abdominal tap yielded coffee-grounds material grossly identical to that obtained through the Levine tube.

CLINICAL DIAGNOSIS

Perforated gastric ulcer

DR ULFELDER'S DIAGNOSES

Duodenal ulcer, repaired

Perforated gastric ulcer

Generalized peritonitis

ANATOMICAL DIAGNOSIS

Multiple perforated peptic ulcers of duodenum.

PATHOLOGICAL DISCUSSION

DR HERRERA At the time of the second laparotomy the ulcer on the anterior duodenal wall was found to be closed over adequately by an omental tab. On the posterior wall, just proximal to the pylorus, a second perforation was found, this measured at least 7 mm in diameter, and through it gastric contents poured out freely. At that point in the operation the patient was no longer breathing and his heart had stopped. We found it impossible to tell how old the second perforation was, in other words, we were not certain whether this man had perforated the second ulcer on the second postoperative day or whether two perforations had been present at the time of the first operation.

DR TRACY B. MALLORY Dr Herrera's description of the findings at the second operation appears to explain adequately the terminal episode. Permission for post-mortem examination was refused.

PEDIATRIC SURVEY

COMPLACENCE is the natural enemy of progress but, fortunately, satisfaction with any level of achievement, if too long indulged, is usually shattered by forces from without, coming to demand a higher grade of production in favor of the consumer. Medicine in this country has not ordinarily needed such stimulation for it has felt the necessity of meeting new challenges, and pediatrics, no less than other branches of medicine, has so far always found ahead of it new standards on which to form its line.

Pediatrics, spurred on perhaps by political rumblings that suggest a storm on the horizon, has now initiated its own psychoanalytical survey, with the American Academy of Pediatrics in the role of

analyst, it has found wisdom in the Socratic injunction to know thyself.

This study of child-health services has already been conducted during the past year in North Carolina as a pilot state, and similar country-wide state programs are about to be launched. A steering committee has been appointed within the American Academy of Pediatrics representing the Academy, the American Pediatric Society and the Medical Advisory Board of the Children's Bureau. Dr. John P. Hubbard, of Boston, has accepted the position as director of the study.

The inquiries to be made will cover four major fields: pediatric education, distribution, qualification and activities of professional personnel, hospital and clinic facilities, and general health services. The study in Massachusetts, soon to be initiated, will be directed by Dr. Lendon Snedeker, of Boston; it has been approved by the Council of the Massachusetts Medical Society.

The work of gathering data will fall on the pediatricians of the state who will be asked to fill out questionnaires concerning their own activities and assist in obtaining information from physicians in private practice and from hospitals. They will also be asked to help publicize the program through newspapers, radio broadcasts and group meetings.

Such a program suggests that the pediatricians of the country intend to do a thorough job in finding out what type of care is being given to our children by hospitals, health services, the general practitioners and themselves. It is hoped that the study will determine, so far as possible, what quality as well as what type of service is delivered, in what proportions pediatric practice is conducted for the benefit of the patient and of the doctor, and what the true standards of service should be.

The evaluation of present methods of child care and the establishment, where necessary, of better ones are undertakings that warrant general support.

DANGERS OF CHEMOPROPHYLAXIS

IN THE past few years, a number of papers have appeared indicating that prolonged and continuous administration of sulfanilamide or sulfadiazine in small doses may be used effectively as a prophy-

lactic against hemolytic streptococcus infections. At first, the writers were concerned primarily with the prevention of recrudescences of rheumatic fever, and the data that they present suggest that such recrudescences were significantly reduced in susceptible individuals, as compared with controls in whom such prophylaxis was not used. Some subjects had to be eliminated from the treated groups because of toxic reactions, which sometimes were quite serious. The types of patients chosen, however, were such that considerable risks were warranted since hemolytic streptococcus infections in them would frequently have been followed by serious rheumatic activity resulting in crippling and even fatal cardiac involvement.¹⁻⁵

It is interesting that positive throat cultures for hemolytic streptococci were not eliminated or prevented and that their incidences were not appreciably reduced among the recipients of this form of prophylaxis. Furthermore, in studies on cases of hemolytic streptococcus tonsillitis and pharyngitis in which therapeutic doses of sulfadiazine had been used, the incidence of Group A hemolytic streptococci in throat cultures was found to be reduced only during the period of treatment, after treatment was stopped, positive cultures were found just as frequently in patients who had been treated with the full doses continuously for three to seven days as they were in comparable untreated cases.⁶⁻⁹

The possibility of developing sulfonamide-resistant strains of pathogenic organisms during treatment with doses of drug that are ineffective for the complete elimination of the infecting organism is a serious and important consideration in the prophylactic use of chemotherapeutic and antibiotic agents. In vitro and in experimental infections in animals such resistance can be readily produced in many organisms by prolonged exposure to subeffective concentrations of these therapeutic agents. Whether this is a process of selection whereby the resistant variants survive or whether it is due to a change in the metabolism of the organism — a sort of acclimatization — is not entirely clear. It is evident, however, that the less susceptible the organism is in the first place, the easier it is to enhance its resistance. Furthermore, it is reasonable to suppose that the extensive and prolonged use of drugs in

subeffective amounts carries with it the greatest danger of the development and spread of resistant strains, irrespective of the mechanism whereby the organisms become resistant. Attention has been called in these columns on previous occasions both to the dangers of the continuous use of sulfonamides to the patient¹⁰ and to the possibility of the development and spread of resistant strains.¹¹ These dangers and the responsibilities of the physician and patient with respect to sulfonamide prophylaxis and treatment have been ably reviewed by Morgan and Turner.¹²

Two types of mass prophylaxis with sulfadiazine have been employed in military establishments. One of these was a brief course, varying from a single dose to several doses given over a period of one or two days, for the purpose of preventing and eliminating meningococcal infections.¹³⁻¹⁵ The other was a continuous administration of small doses of sulfadiazine over several weeks, given primarily for the purpose of preventing hemolytic streptococcus diseases.¹⁶⁻¹⁸ The former resulted in immediate and almost complete elimination both of infections and of carriers until the organisms were gradually introduced again from outside. The latter produced a reduction in manifest streptococcal diseases without eliminating the organisms from carriers or preventing their spread. These results could have been anticipated from the extreme sensitivity of the meningococcus to sulfadiazine on the one hand and the resistance of the hemolytic streptococci on the other. Resistance or fastness of meningococci to sulfadiazine is produced with the greatest difficulty even in vitro, whereas it is readily produced in streptococci. Other factors concerned with the host-parasite relation may also be of equal or greater importance with respect to these two organisms, but they are difficult to evaluate. At any rate, the anticipated effect of the continued use of sulfadiazine in small doses in a population heavily infected with virulent streptococci finally materialized. Resistant strains of hemolytic streptococci spread throughout several of the units where sulfadiazine prophylaxis was being carried out. These resistant strains essentially replaced susceptible strains and gave rise to rather extensive outbreaks of hemolytic streptococcus infections.

Two reports of such a sequence of events in different Navy training stations have recently been reported,^{19, 20} and others have undoubtedly occurred. It is difficult to tell without a considerably greater amount of information than has been made available thus far whether the widespread prophylactic program adopted by the Navy had the total effect on the training program that was anticipated by the medical authorities. Data, likewise, are lacking from which one can estimate just how much harm was done in misdiagnosed or improperly treated cases as a result of sensitization or from other toxic effects that resulted directly or indirectly from this prophylactic regime. It is clear from these experiences, however, that sulfonamide prophylaxis on a large scale and over a long period carries with it considerable possibilities of harm, which must always be weighed against the anticipated benefits.

No doubt the availability of penicillin in large quantities, particularly in the form of troches and oral preparations, has suggested to many physicians the possibility of its continuous use in the prophylaxis of various types of infections. Although fewer and perhaps less serious toxic effects may be expected from penicillin than from the sulfonamides, the possibilities for harm should be explored under rigidly controlled conditions before any such programs are undertaken.

MASSACHUSETTS MEDICAL SOCIETY

REVIEW LECTURE COURSE

The following is a detailed program of the balance of the Review Lecture Course, which concludes on May 15

APRIL 17 ALLERGY *Chairmen* John L. Fromer and Francis M. Rackemann

3:00-4:45 Round-Table Discussion on Hay Fever and Asthma. Walter Burrage, assistant physician, Massachusetts General Hospital; Calvin B. Faunce, consulting surgeon, Massachusetts Eye and Ear Infirmary; John L. Fromer, director, Department of Allergy and Dermatology, Lahey Clinic; J. Everts Greene, assistant in medicine, Massachusetts General Hospital; Sanford B. Hooker, professor of immunology, Boston University School of Medicine; Francis M. Rackemann, lecturer in medicine, Harvard Medical School, physician, Massachusetts General Hospital; Leroy E. Schall, professor of laryngology, Harvard Medical School, chief, Department of Otolaryngology, Massachusetts Eye and Ear Infirmary.

NOSE AND THROAT DISEASES *Chairmen* Calvin B. Faunce and Leroy E. Schall

4:45-5:30 DEAFNESS AND WHAT CAN BE DONE ABOUT IT. Moses H. Lurie, assistant professor of otology, Harvard Medical School, surgeon in otology, Massachusetts Eye and Ear Infirmary, consulting otolaryngologist, Massachusetts General Hospital.

5:30-6:00 Emergencies Involving the Nose, Throat and Bronchi. John R. Richardson, instructor in laryngology, Harvard Medical School, assistant surgeon, Massachusetts Eye and Ear Infirmary, assistant surgeon, Massachusetts General Hospital.

APRIL 22 DISEASES OF THE CHEST *Chairmen* Donald S. King and John W. Strieder

5:00-5:30 Public-Health Aspects of Tuberculosis in Massachusetts. Alton S. Pope, deputy commissioner and director of the Division of Tuberculosis, Massachusetts Department of Public Health.

5:30-6:00 The Present Concept of the Treatment of Pulmonary Tuberculosis. Paul Dufault, superintendent, Rutland State Sanatorium.

6:00-6:30 Important Points to Remember in Treating Lung Conditions. Theodore L. Badger, chief-of-staff, Channing Home, instructor in medicine, Harvard Medical School.

7:30-8:15 Pulmonary Carcinoma and Other Growths in the Chest. Ralph H. Adams, surgeon, Lahey Clinic.

8:15-9:00 Pulmonary Abscess, Bronchiectasis and Other Suppurative Chest Conditions. Richard H. Sweet, associate visiting surgeon, Massachusetts General Hospital, instructor in surgery, Harvard Medical School.

APRIL 24 NEUROPSYCHIATRY *Chairmen* Raymond D. Adams and Harry C. Solomon

3:00-3:35 Psychosomatic Medicine. Stanley Cobb, psychiatrist-in-chief, Massachusetts General Hospital.

3:35-4:05 Psychoneurosis and the Veteran. John Murray, consultant in psychiatry, Massachusetts Institute of Technology.

4 05-4 40 Insulin-Shock and Electric-Shock Therapy and Lobotomy Gaylord P Coon medical officer, Boston Psychopathic Hospital, junior associate, Peter Bent Brigham Hospital

4 40-5 20 Neurosyphilis Augustus S Rose member of staff, Psychopathic Hospital, consultant, Massachusetts General, Peter Bent Brigham, New England Baptist and Newton hospitals

5 20-6 00 Epilepsy William G Lennox visiting physician, Children's Hospital, visiting neurologist, Boston City Hospital, assistant in neurology, Peter Bent Brigham Hospital

APRIL 29 NEUROPSYCHIATRY (Continued)

5 00-5 30 Headache Derek Denny-Brown professor of neurology, Harvard Medical School, director, Neurological Unit, Boston City Hospital

5 30-6 00 Pyogenic Intracranial Infections Charles S Kubik neurologist and neuropathologist, Massachusetts General Hospital

6 00-6 30 Apoplexy Raymond D Adams visiting neurologist and neuropathologist and assistant director, Neurological Unit, Boston City Hospital, consultant in neurology, Pratt Diagnostic Hospital, lecturer in neurology, Tufts College Medical School

APRIL 29 ENDOCRINOLOGY Chairmen Edwin B Astwood and Lewis M Hurxthal

7 30-8 15 Progress in Endocrinology and Thiouracil in the Treatment of Hyperthyroidism Edwin B Astwood research professor of medicine, Tufts College Medical School

8 15-9 00 Diagnosis and Treatment of Thyroid Disease Frank H Lahey director, Lahey Clinic, surgeon-in-chief, New England Baptist and Deaconess hospitals

MAY 1 ENDOCRINOLOGY Chairmen Edwin B Astwood and Lewis M Hurxthal

3 00-3 30 Childhood Obesity and Related Problems Richard Wagner assistant professor of pediatrics, Tufts College Medical School, physician, Boston Floating Hospital

3 30-4 00 Hypothyroidism and Hypopituitarism Lewis M Hurxthal director, Department of Medicine, Lahey Clinic, physician, New England Baptist and Deaconess hospitals

4 00-4 30 Treatment of Addison's Disease George W Thorn Hersey Professor of the Theory and Practice of Physic, Harvard Medical School, physician-in-chief, Peter Bent Brigham Hospital

4 30-5 15 Hyperparathyroidism Oliver Cope assistant professor of surgery, Harvard Medical School, associate visiting surgeon, Massachusetts General Hospital

5 15-6 00 Male Hypogonadism and the Therapeutic Use of Androgens Robert W Williams associate in medicine, Harvard Medical School, junior visiting physician and assistant, Thorndike Memorial Hospital, Boston City Hospital

MAY 6 DISEASES OF THE EYE Chairmen Edwin B Dunphy and Benjamin Sachs

5 00-6 00 Ophthalmology in General Practice Benjamin Sachs professor of ophthalmology, Tufts College Medical School Edwin B Dunphy chief of ophthalmology, Massachusetts Eye and Ear Infirmary

DIABETES MELLITUS Chairmen W Richard Ohler and Howard F Root

6 00-6 30 Diagnostic Methods Priscilla White instructor in pediatrics, Tufts College Medical School, physician, New England Deaconess Hospital

Dietary Treatment Joseph Rosenthal assistant professor of medicine, Tufts College Medical School, supervisor in charge of teaching, Boston Dispensary

7 30-9 00

The Insulins George Ballantyne director, Diabetic Clinic, Worcester City Hospital

Complications James Townsend associate physician, Massachusetts General Hospital

Acidosis and Coma Howard F Root associate in medicine, Harvard Medical School, physician-in-chief, New England Deaconess Hospital

Advances in Diabetes Elliott P Joslin clinical professor of medicine (emeritus), Harvard Medical School, medical director, George F Baker Clinic, New England Deaconess Hospital

MAY 8 GYNECOLOGY Chairmen Joc V Meigs and John Rock

3 00-3 45 Menstruation, Its Disorders and Their Treatment John Rock instructor in gynecology, Harvard Medical School, visiting surgeon, Free Hospital for Women

3 45-4 30 Office Problems, Diagnostic Methods and Treatment James C Janney professor of gynecology, Boston University School of Medicine

4 30-5 15 Diagnosis of Cancer Joc V Meigs clinical professor of gynecology, Harvard Medical School, chief, Vincent Memorial Hospital and Gynecological Service, Massachusetts General Hospital

5 15-6 00 Treatment of Cancer George Van S Smith visiting surgeon and director of the Fearing Research Laboratory, Free Hospital for Women

MAY 13 OBSTETRICS Chairmen Alonzo K Paine and Duncan E Reid

5 00-6 30 and 7 30-9 00 A Critical Review of Progress in Obstetrics During the Last Four Years, including a Consideration of Certain Immediate Problems of the Newborn Roy J Heffernan visiting obstetrician and gynecologist, Carney Hospital Harold H Rosenfield visiting surgeon in obstetrics and gynecology, Boston City Hospital Stewart H Clifford pediatrician, Boston Lying-in Hospital associate visiting physician, Children's Hospital Arthur T Hertig pathologist and obstetrician to Out-Patient Department, Boston Lying-in Hospital

MAY 15 SURGICAL GENITOURINARY DISEASES AND VENEREAL DISEASES Chairmen Roger C Graves and Samuel N Vose

3 00-3 40 Prostatism George G Smith visiting urologist, Massachusetts General Hospital, urologist, Palmer Memorial Hospital

3 40-4 25 The Female Bladder Samuel N Vose professor of genitourinary surgery, Boston University School of Medicine, urologist, Massachusetts Memorial Hospitals

4 25-5 00 Epidemiology of Venereal Disease Erwin C Drescher surgeon, United States Public Health Service

5 00-5 30 Recent Advances in the Management of Gonorrhea in the Male J Hartwell Harrison urological surgeon, Peter Bent Brigham Hospital

5 30-6 00 Progress in the Diagnosis and Treatment of Syphilis John G Downing professor of dermatology and syphilology, Tufts College Medical School, professor of dermatology, Boston University School of Medicine, dermatologist-in-chief, Massachusetts Memorial, Boston City and St Elizabeth's hospitals

CORRESPONDENCE

DEPRIVATION OF LICENSE

To the Editor At a meeting of the Board of Registration in Medicine held March 15, the Board took the following actions

To suspend the registration of Dr Edmond J MacDonald, 24 Wheatland Street, Somerville, for six months because of gross misconduct in the practice of his profession as shown by his treatment of patients

To revoke the registration of Dr Earl Burton Carr of Cassadago, New York, and Bar Harbor, Maine, because of gross misconduct in the practice of his profession as shown by his conviction of a felony in New York State

H QUIMBY GALLUP, M D, Secretary,
Board of Registration in Medicine

State House
Boston

ALTERNATING PLEURISY WITH EFFUSION AS A MANIFESTATION OF TUBERCULOSIS*

A Report of Seven Cases

KENNETH T. BIRD, M.D.†

WALTHAM, MASSACHUSETTS

THE syndrome of alternating pleurisy with effusion is characterized by the development of serofibrinous pleurisy, at first unilateral and later contralateral. The onset and course of each effusion associated with this syndrome differ in no way from that of the more frequent purely unilateral type of pleurisy. Occurring as it does in the absence of pulmonary infiltration or with only a suspicion of it, this condition presents a diagnostic, therapeutic and prognostic challenge.

This syndrome has received scant clinical attention, and only isolated case reports have appeared. Gray¹ describes alternating pleurisy with effusion in an eighteen-year-old boy, with death resulting from miliary tuberculosis and tuberculous meningitis. Hurrell and Dawson-Walker² report a single case of alternating pleurisy with effusion occurring in a twenty-six-year-old man. Autopsy revealed generalized miliary tuberculosis. Gordon³ briefly cites a case seen by Theodos of alternating pleural effusion with subsequent ascites developing in the presence of Pott's disease of the spine.

Hitherto, alternating pleurisy with effusion has been termed "bilateral pleurisy with effusion." It seems desirable to reserve the latter term for the rare cases of acute simultaneous bilateral pleurisy with effusion, thus demarcating the definite syndrome of alternating pleurisy with effusion.

Wilson⁴ has summarized 14 cases of bilateral pleurisy with effusion. Of these, only 3 developed in the absence of demonstrable pulmonary infiltration and thus seemingly fall into the category under discussion, but it is not clear whether these cases represent alternating pleurisy with effusion or acute simultaneous bilateral pleurisy with effusion. It is probable that most cases of acute bilateral pleurisy with effusion actually represent alternating pleurisy with effusion, first discovered when bilateral effusion was present.

Cases of alternating pleurisy with effusion with definite evidence of widespread pulmonary tuberculosis are not included in the syndrome of alternating

pleurisy with effusion, because the diagnosis is usually obvious. Effusions occurring during the course of bilateral therapeutic pneumothorax likewise are not considered, nor are the occasional cases of contralateral effusion developing after a unilateral artificial pneumothorax, with an accompanying effusion.

Acute serofibrinous pleurisy is of tuberculous origin in many, if not all, cases. Numerous follow-up studies, recently summarized by Farber,⁵ attest to the serious ultimate prognosis of so-called serofibrinous pleurisy, an apparently benign and transient disease. Thirty to fifty per cent of cases of pleurisy with effusion later develop pulmonary tuberculosis. Occasionally miliary tuberculosis follows or accompanies such an effusion, and extrapulmonary tuberculosis is not infrequently a complication.

That alternating pleural effusion may be a manifestation of tuberculosis is shown by the following cases seen at the Middlesex County Sanatorium.

CASE REPORTS (FIGS 1 and 2)

CASE 1 H. S. (M.C.S. 2155), a 30-year-old, married housewife, a sextigravida, when in the 5th month of pregnancy developed left-sided pleurisy and was hospitalized elsewhere on March 11, 1939, for 7 days. A roentgenogram of the chest showed a marked left-sided pleural effusion. A diagnostic thoracentesis was performed, and the fluid obtained was reported as positive for tuberculosis by guinea-pig inoculation. Because of recurrence of left-sided chest pain, the patient was readmitted elsewhere on March 29. A roentgenogram again showed a marked left-sided effusion. Following thoracentesis and further symptomatic treatment, she was discharged on April 12, somewhat improved.

The patient was first seen at the Diagnostic Clinic of the Middlesex County Sanatorium on April 24. A chest roentgenogram still showed a left-sided pleural effusion with cardiac displacement. Because she was in the 6th month of pregnancy, bed rest at home was advised. On July 30, acute right-sided pleuritic pain developed and she was again hospitalized elsewhere. A right-sided pleural effusion was present. On August 1, she delivered a normal baby, who died 1 week later.

The patient was admitted to this hospital on August 14 with a slight cough, minimal expectoration and a temperature of 103°F. A roentgenogram of the chest showed a right-sided pleural effusion, with slight haziness only at the left costophrenic angle. A right-sided thoracentesis performed on August 18 produced hazy amber fluid, which was positive for tuberculosis by guinea-pig inoculation. There was progressive improvement, and a roentgenogram taken on No-

*From the Middlesex County Sanatorium.

†Formerly resident in tuberculosis, Middlesex County Sanatorium, and instructor, Department of Preventive Medicine, Tufts College Medical School, Boston.

left definite minimal infiltration in the 1st interspace, with thickened pleura at the base. No symptoms were associated with the appearance of this effusion. A right-sided thoracentesis performed on May 22 yielded 300 cc. of blood-tinged fluid, which was positive for tuberculosis by guinea-pig inoculation. On May 29, the fasting gastric content was negative for tuberculosis by guinea-pig inoculation, but routine 72-hour sputum concentrates on July 5 and August 14 were both positive for tubercle bacilli (Gaffky II) on a Ziehl-Neelsen smear. The patient is still hospitalized.

Comment There was an acute onset of left-sided effusion, with a negative culture, followed by asymptomatic right-sided effusion, with the fluid positive by guinea-pig inoculation, in the presence of definite minimal left-sided infiltration that was previously only suspected. The interval between effusions was 3 months. The sputum eventually became positive.

CASE 3 D W (MCS 3927), a 25-year-old, unmarried Chinese woman developed a cough in February, 1945, which was diagnosed as bronchitis. On March 2, there developed slight pain in the thorax and acute diffuse abdominal swelling.

The patient was admitted to this hospital on May 16, with moderate ascites and a small left-sided pleural effusion without parenchymal disease. A tuberculin test (0.01 mg.) was positive. The past history revealed that on May 12, 1943, because of vague abdominal complaints, laparotomy had been performed elsewhere. Considerable induration of the lower ileum was found. An appendectomy was performed, with removal of a cyst of the left ovary and of the left fallopian tube. Tuberculous peritonitis was considered but not proved. The pathological diagnoses were endometrial cyst of the ovary, chronic pyelonephritis and questionable chronic appendicitis.

Clear, straw-colored fluid obtained by a left-sided thoracentesis on May 22 was negative for tuberculosis by guinea-pig inoculation. The aspirated gastric content on May 24 was negative for tuberculosis on guinea-pig inoculation. Specimens of the sputum were negative on concentration.

In early June, while the patient was still hospitalized, a slight cough, right-sided chest pain, dyspnea and a temperature of 100°F developed. On June 9 a chest roentgenogram showed a massive right-sided pleural effusion, with considerable absorption of fluid on the left. Four hundred cubic centimeters of thin, slightly cloudy, straw-colored fluid obtained by thoracentesis on June 12 was positive for tuberculosis by guinea-pig inoculation. By June 19 there was no evidence of ascites. Despite further aspiration in an attempt to prevent fixation, a right-sided fibrothorax has developed, with marked limitation of right hemithoracic movement. The patient is still hospitalized.

Comment The insidious onset of left-sided pleural effusion, with the fluid negative by guinea-pig inoculation, was coincidental with transient ascites, followed by the gradual onset of right-sided effusion, with the fluid positive. The interval between effusions was 3 months. Previous laparotomy suggested tuberculous peritonitis. There was eventual development of right-sided fibrothorax.

CASE 4 M O (MCS 2275), a 33-year-old, married housewife, developed a slight cough with pain in the left posterior chest in January, 1938, when 1 month pregnant. In March, malaise increased, slight fever began, and a heavy feeling developed in the left side of the chest. A roentgenogram taken on March 30 showed a left-sided pleural effusion. A left-sided thoracentesis performed elsewhere on March 31 yielded 480 cc. of fluid, which was negative for tuberculosis by guinea-pig inoculation. On May 29, vaginal bleeding began, and on June 2, incomplete miscarriage occurred. Curettage was done elsewhere on June 4, and convalescence was normal until June 17, when the temperature rose to 103°F and a septic course developed. On June 25, a left-sided diagnostic thoracentesis yielded fluid that was positive for tuberculosis by guinea-pig inoculation. On July 6, the patient was transferred to another hospital, where a left-sided thoracentesis yielded fluid containing anaerobic nonhemolytic streptococci. On July 9, rib resection for tube drainage was done. A pleural biopsy showed tuberculous granulation tissue.

The patient was transferred to this hospital on July 29 with a diagnosis of mixed tuberculous and nonhemolytic streptococcus empyema, with no evidence of parenchymal disease, but left against advice on the 13th day.

Irrigation of the draining empyema cavity was done at home until September, when the temperature rose to 104°F and the patient was hospitalized elsewhere. A secondary hemolytic streptococcal infection of the empyema cavity was found. The cavity had decreased in volume from about 200 cc. to 120 cc.

The patient was readmitted to this hospital on October 6. Empyema fluid was positive for tuberculosis by guinea-pig inoculation and also showed diphtheroids, streptococci and staphylococci. Frequent irrigations of the empyema cavity resulted in slow improvement. On February 14, 1939, a left-sided Schede thoracoplasty, with partial removal of the 6th, 7th, 8th, 9th and 10th ribs was done, but the incision broke down postoperatively. No further interference was advised because of the patient's condition, and she was discharged on September 21 after 351 days of residence.

Wound irrigations were continued at home. The patient remained fairly well until January, 1940, when she developed pain in the right side of the chest, cough, a temperature of 101°F, dyspnea and nausea. She was readmitted to this hospital on January 18 with a moderate right-sided pleural effusion. The left-sided thoracic incision was still open and draining. A right-sided thoracentesis on January 19 yielded 900 cc. of thin, cloudy, amber fluid, with the specific gravity 1.025, the red-cell count 637, and the white-cell count 360, with 1 per cent polymorphonuclear leukocytes, 96 per cent lymphocytes, 2 per cent eosinophils and 1 per cent undetermined forms. The fluid was negative for tuberculosis by guinea-pig inoculation. By April 9 there was only slight blunting of the right costophrenic angle with fluid. A three-stage left anterolateral thoracoplasty was begun on April 10 and completed on May 15. The patient did well postoperatively, the new incision healed fully, and closure of the old draining wound began. The sputum was never positive. She was discharged on October 1, 1941, after 623 days of residence.

By April, 1944, the old wound was fully healed without drainage. When last seen on April 9, 1945 the patient was essentially well but on limited activity. A roentgenogram of the chest showed a left-sided thoracoplasty with excellent lateral compression. The right lung was clear, with a normal-appearing right costophrenic angle.

Comment There was an insidious onset of left-sided pleural effusion, with the fluid positive by guinea-pig inoculation, which after an incomplete miscarriage became secondarily infected and eventually required a left-sided Schede thoracoplasty. This was not successful and was followed by acute right-sided effusion, with the fluid negative by guinea-pig inoculation. The interval between effusions was 24 months. A left-sided thoracoplasty was required for final control. This catastrophic series of events could have undoubtedly been prevented by the present-day use of penicillin.⁴

CASE 5 A Z (MCS 2001), a 35-year-old, married housewife, with no known contact with tuberculosis, experienced the insidious onset of right-sided pleurisy in December, 1938. On January 8, 1939, she developed shaking chills and a temperature of 103°F. A roentgenogram of the chest taken elsewhere showed a right-sided pleural effusion from the 7th rib downward. A smear of the fluid showed no acid-fast organisms, 98 per cent of the cells were lymphocytes, and 2 per cent were polymorphonuclear leukocytes. Guinea-pig inoculation was not done. On February 15, when the patient was first seen in the Diagnostic Clinic, an attempted thoracentesis was unsuccessful.

The patient was admitted to this hospital on February 27, 1939. A 72-hour specimen of sputum taken on March 6, 1939, by the Greenfield-Anderson technic was positive for tubercle bacilli (Gaffky II), and stereoscopic roentgenograms on March 29 showed definite infiltration on the left, extending out from the upper pole of the hilum posteriorly to the 3rd rib and consistent with minimal pulmonary tuberculosis. This gradually retrogressed. Further sputum specimens remained negative. The patient was discharged on September 22 after 208 days of routine sanatorium care.

She remained well until November 19, when she developed acute left-sided chest pain, chills, a temperature of 102°F, cough and expectoration. Examination showed dullness to percussion with poor to absent breath sounds at the left base anteriorly and posteriorly. A chest roentgenogram taken on November 29 showed haziness at the extreme costophrenic angle on the right and a left-sided pleural effusion.

The patient refused readmission but took bed rest at home for 4 months. Thoracentesis was not done. By May, 1940, she was asymptomatic, and a roentgenogram showed only a small amount of fluid at the left base. In July, 1945, she was still well, and a roentgenogram showed the lungs to be clear and the costophrenic angles normal.

Comment There was an acute onset of right-sided effusion and later transient left-sided infiltration, with a single sputum specimen positive. This was followed by acute left-sided effusion. The interval between effusions was 10 months.

CASE 6 M⁺B (MCS 3502), a 36-year-old, divorced woman, was first seen in the Diagnostic Clinic on November 23, 1939, because of contact with her brother, who was under

chest pain. A massive left-sided pleural effusion with cardiac displacement was shown on examination and by chest roentgenogram.

The patient was readmitted on November 3, 1943. A left-sided thoracentesis yielded 600 cc. of Burgundy-red fluid, which was negative by guinea-pig inoculation. Fluid aspirated on November 12 and 27 was also negative. Sputum concentrates were consistently negative. Liver injections were begun, and the red-cell count rose from 3,430,000, with a hemoglobin of 78 per cent (Sahli), on admission to 4,000,000 on April 4, 1944, and to 4,850,000, with a hemoglobin of 88 per cent, on discharge. On March 7, the fasting gastric content was negative by guinea-pig inoculation. On

FIGURE 2

treatment for pulmonary tuberculosis. A chest roentgenogram was negative. Because of fatigue and weight loss, roentgenograms were taken elsewhere in September, 1941, and a diagnosis of tuberculosis was made.

On October 2, 1941, the patient was admitted to this hospital. A tuberculin test (0.01 mg.) was positive. A roentgenogram showed mixed infiltration on the left, extending from the hilum to the 2nd interspace. Seven 72-hour sputum concentrates, two gastric aspirations with guinea-pig inoculation and a sputum inoculated into a guinea pig were negative. The patient left the hospital against advice on December 26 after 86 days of residence. After discharge she was seen periodically in the clinic and remained free of respiratory complaints, but in November, 1942, a diagnosis of pernicious anemia (later confirmed) was made elsewhere and injections of liver extract were begun. In October, 1943, she developed an unproductive cough and a temperature of 102°F, without

routine sanatorium regimen the patient progressed satisfactorily until April 18, when severe cough, right-sided chest pain, shortness of breath and a temperature of 102°F developed coincidentally with a right-sided pleural effusion. A roentgenogram showed persistent effusion on the left and moderate effusion on the right. On April 24, 600 cc of amber cloudy fluid was aspirated from the right side of the chest. On May 1 and 15, a right-sided thoracentesis yielded 850 cc and 200 cc, respectively, of clear, yellow fluid. No tubercle bacilli were demonstrated on smear. Guinea pigs were not available, but on each occasion the fluid was negative for tubercle bacilli on culture. The temperature became normal within 8 weeks, and there was slow improvement. The patient was discharged at her own request on November 3 after 367 days of residence. A chest roentgenogram taken at that time showed thickened pleura or fluid at both bases, extending upward toward the axillas, with mixed infiltration

about the left hilum extending into the 2nd and 3rd interspaces

The patient failed to keep regular clinic appointments, and when seen on August 27, 1945, she had developed severe cough, expectoration, ascites and edema of the ankles. A chest roentgenogram showed exudative infiltration throughout both lung fields, with persistence of marginal pleural reaction consistent with miliary tuberculosis. Sanatorium readmission was advised, but the patient died at home on September 1. Permission for autopsy was not obtained.

Comment There was an acute onset of left-sided effusion, with the fluid negative by guinea-pig inoculation, in the presence of suspicious left-sided hilar infiltration, with repeated negative sputum and gastric contents. This was followed by acute right-sided effusion, with a negative culture. The interval between effusions was 6 months. There was eventual development of miliary pulmonary lesions. The cause of death was not ascertained but was undoubtedly tuberculous.

CASE 7 O P (MCS 796), a 21-year-old, married Negro cook, experienced the gradual onset of a slightly productive cough, dyspnea on exertion, a temperature in April, 1934, of 103°F and weight loss. He was hospitalized elsewhere on May 9, when a chest roentgenogram showed a massive right-sided pleural effusion with cardiac displacement. Thoracentesis on May 11, 1934, yielded yellow-red fluid, with the specific gravity 1.020, the red-cell count 7,000 and the white-cell count 0. By May 28 the fluid had become yellow, with the specific gravity 1.018, the red-cell count 4,000 and the white-cell count 500, all lymphocytes. Intradermal injection of old tuberculin (0.1 mg) was positive. Guinea-pig inoculation of aspirated fluid was negative for tuberculosis. Ten sputum examinations showed no acid-fast organisms.

On August 31, the patient was transferred to this hospital. A chest roentgenogram showed a right-sided pleural effusion, with no evidence of parenchymal disease. A right-sided thoracentesis performed on September 8 yielded 50 cc of clear, greenish fluid, which was negative for tubercle bacilli by guinea-pig inoculation and on culture using Parker's medium. The patient was discharged on November 23 after a total hospital residence of 218 days, 85 of which were spent in this hospital.

He continued well until March 18, 1935, when a small asymptomatic effusion blunting the left base appeared. A thoracentesis performed on April 18, 1935, was unsuccessful. The patient was closely followed in the clinic, and by May 28 the fluid had disappeared. He continued asymptomatic and on October 10, 1944, was essentially well. A chest roentgenogram taken at that time showed a horizontal right diaphragm, but the lungs were clear.

Comment There was a gradual onset of right-sided effusion, with the fluid negative by guinea-pig inoculation. This was followed by an asymptomatic transient left-sided effusion. Thoracentesis was unsuccessful. The interval between effusions was 10 months.

DISCUSSION

The apparent incidence of alternating pleurisy with effusion is low. Among 3822 patients with pulmonary tuberculosis admitted to this sanatorium between September 31, 1931, and September 1, 1945, only 7 cases of alternating pleurisy with effusion were found. During this same interval 48 patients with pleurisy with effusion were admitted. Since Amberson⁷ has estimated that in 5 per cent of all cases of pulmonary tuberculosis the serous membranes are involved, it is obvious that only a small percentage of patients with serofibrinous pleurisy are admitted for sanatorium treatment. This is presumably due to the general failure to appreciate both the serious prognosis of serofibrinous pleurisy and the need for sanatorium treatment. Hence, although the statistical incidence of alter-

nating pleurisy with effusion is low, the syndrome is undoubtedly more frequent than is generally realized.

The pathogenesis of alternating pleurisy with effusion is presumably hematogenous. Tuberculous bacilemia is more frequent than is usually appreciated.⁸

Diagnosis

In the syndrome described, the onset and course of the pleurisy with alternating effusion differed in no way from the onset and course of unilateral serofibrinous pleurisy.⁵

Serofibrinous pleurisy may be of acute or insidious onset, with malaise, fever, cough, variable expectoration and often dyspnea. Ordinarily the active phase of the effusion lasts for four to six weeks, sometimes longer. Occasionally the effusion is transient and asymptomatic, being discovered during routine examination.

The cases presented above show features characteristic of those accepted as clinically diagnostic of so-called serofibrinous pleurisy.⁷ As with unilateral pleurisy with effusion, extrapulmonary tuberculosis may precede, accompany or follow alternating pleurisy with effusion.

Thoracentesis is indicated to establish the nature and etiology of a pleural effusion in the absence of obvious systemic disease. The fluid of serofibrinous pleurisy is an exudate. The cells are predominantly lymphocytes, but rarely the fluid is hemorrhagic.⁹ Importance, but not pathognomonic significance, can be attached to such a lymphocytosis, for effusions due to carcinoma and to pulmonary emboli may also show this feature.⁹

Guinea-pig inoculation or culture of aspirated fluid is definitely indicated in serofibrinous pleurisy with effusion. Examination of the smear alone for tubercle bacilli is insufficient. In a series of 119 consecutive cases of pleural effusion, occurring chiefly during the course of therapeutic pneumothorax, from different cases routinely studied at the Middlesex County Sanatorium in 1941-1942 and found to be positive for tuberculosis, the fluid in 45 cases was positive—usually Gaffky II or more—on smear (Ziehl-Neelsen stain), and guinea-pig inoculation was accordingly not done. In 74 cases, the fluid was positive on smear and also positive by guinea-pig inoculation. In 67 cases, it was negative on smear but positive by guinea-pig inoculation. Furthermore, of the 24 patients admitted to this sanatorium from 1931 to 1940, inclusive, with a diagnosis of pleurisy with effusion, thoracentesis yielded fluid that was positive (Gaffky II) on smear (Ziehl-Neelsen stain) in only 1 case. In 10 cases the fluid was negative on smear but positive for tuberculosis by guinea-pig inoculation. In 7 cases, it was negative both on smear and by guinea-pig inoculation. In 6 cases, the result of examination was not reported.

Amberson¹⁰ has pointed out that concentration of a larger volume of pleural fluid before guinea-pig

inoculation can logically be expected to increase the percentage of positive tests. On the other hand a negative result of guinea-pig inoculation does not exclude a tuberculous origin. A later aspiration may yield fluid that is positive. In Case 4, the fluid originally aspirated from the left side of the chest was negative for tuberculosis by guinea-pig inoculation but was positive three and a half weeks later. Similarly, in the case reported by Hurrell and Dawson-Walker² both fluids originally aspirated were negative but later were positive. Furthermore, as shown in Table 1, there is a high incidence of

TABLE 1 Results of Guinea-Pig Inoculation of Pleural Fluid in Pleurisy with Effusion

AUTHOR	No. of Cases	POSITIVE*	NEGATIVE*
Bouillaud	22	7 (2)	15 (7)
Gaardar	79	22 (15)	57 (26)
Totals	101	29 (17)	72 (33)
Percentage of cases developing tuberculosis		58	45

*The figures in parentheses represent patients who later developed tuberculosis, chiefly pulmonary

pulmonary tuberculosis following the development of serofibrinous pleurisy, despite negative results of guinea-pig inoculation.

A final diagnostic procedure that should be used more frequently than at present is guinea-pig inoculation of the fasting gastric content or of sputum if it is being produced. Infrequent cases with a positive guinea-pig inoculation of the gastric content or of sputum in the presence of negative pleural-fluid findings, with no roentgen-ray evidence of pulmonary infiltration, have been observed at this sanatorium.

Differential Diagnosis

There are numerous causes of pleural effusion. Tinney and Olsen¹³ have analyzed 274 cases seen at the Mayo Clinic, with the results indicated in Table 2.

Alternating pleurisy with effusion occurring in the course of such diseases as congestive failure,

TABLE 2 Proved Etiology of Pleural Effusion

ETIOLOGY	No. of Cases	PERCENTAGE
Carcinoma	141	51
Congestive failure	42	15
Lymphoma	28	10
Pneumonia	24	9
Tuberculosis	16	6
Cirrhosis of liver	8	3
Chronic nephritis, with nephrosis	7	3
Miscellaneous conditions	8	3
Total	274	

pulmonary infection, polyserositis (Concato's disease), metastatic carcinoma, lymphoma, cirrhosis, septicemia, rheumatic fever or nephritis should be easily distinguished from the syndrome described above and thus offer no difficulty.

A nontuberculous bacterial etiology of the syndrome under discussion has been excluded, since routine cultures of the effusions were negative except, of course, in Case 4, in which was a secondary infection.

Certain relatively infrequent diseases may have to be considered on occasion.

That alternating pleural effusion may be an incident in the course of a polyserositis associated with disseminated lupus erythematosus is admitted. Not one of the cases summarized above, however, showed suggestive skin lesions, leukopenia, albuminuria, pericardial effusion, joint symptoms or other evidence of the characteristic widespread polyserositis associated with disseminated lupus. Furthermore, after variable follow-up periods no suggestive symptoms have developed.

Pulmonary emboli with accompanying effusion may conceivably give rise to the syndrome of alternating pleural effusion. Careful physical examination, with special reference to calf tenderness, presence of Homans's sign and alteration in the diameter of the calf, together with consideration of the associated and characteristic roentgenographic findings,¹⁴ should easily exclude such a possibility.

Severe nutritional disturbances with hypoproteinemia or marked vitamin B deficiency may give rise to serous effusions that are rarely pleural and may possibly simulate the syndrome under discussion.

Chronic constrictive pericarditis — frequently of tuberculous origin — with the characteristic symptoms of dyspnea, abdominal enlargement and often ankle edema may be accompanied by pleural effusion. The fluid is usually a transudate. Similarly, since the fluid of Meigs's¹⁵ syndrome is characteristically a transudate, no diagnostic confusion should arise even though the course of this disease may mimic alternating pleural effusion. Finally, Loeffler's syndrome, characterized by transient, recurrent pulmonary infiltration, a parasitic infestation or an allergic background, a benign clinical course and eosinophilia, has recently been shown to be a rare cause of bilateral pleural effusion and hence a potential cause of alternating pleurisy with effusion.¹⁶ Thus, a twenty-one-year-old man with characteristic infiltration in both lungs developed bilateral pleural effusion. Culture and guinea-pig inoculation were both negative for tubercle bacilli. The fluid from the right side contained 29 per cent eosinophils, and that from the left side contained 64 per cent eosinophils, which appears to be a distinguishing feature.

Exclusion of any of the above conditions should not be difficult if one is familiar with the nature of serofibrinous pleurisy with effusion.

Treatment

As in acute serofibrinous pleurisy with effusion, the early treatment is symptomatic. Thoracentesis

is indicated initially for diagnosis and to visualize the underlying lung parenchyma, to relieve respiratory, cardiac or gastric embarrassment produced mechanically and occasionally to help in hastening fluid resorption

Although the acute phase of serofibrinous pleurisy ordinarily lasts for four to six weeks, several months of a sanatorium regime is an essential part of proper treatment Amberson⁷ states that serofibrinous pleurisy with effusion should be treated as is active tuberculosis, with sanatorium care Trudeau¹⁷ has shown that the prognosis of pleurisy with effusion with either negative or minimal apical pulmonary findings is excellent in patients receiving at least four months of sanatorium treatment Gaarde's¹² findings are in agreement Obviously, alternating pleurisy with effusion, a variety of acute serofibrinous pleurisy and a manifestation of tuberculosis, should be treated in a comparable fashion, with prolonged bed rest

Chest roentgenograms taken at least semiannually for a period of five years are part of proper follow-up supervision if possible parenchymal infiltration is to be discovered early Since the early infiltration of pulmonary tuberculosis is notoriously silent, both symptomatically and clinically, it is only by frequent roentgenograms that pulmonary tuberculosis following serofibrinous pleurisy can be discovered before extensive progression has taken place.

Prognosis

Alternating pleurisy with effusion may be a disease of serious ultimate significance in the absence of proper treatment Although no conclusions can be drawn from this small group of cases, it appears that a sanatorium regimen or its equivalent is necessary if the likelihood of eventual development of pulmonary or extrapulmonary tuberculosis is to be reduced to a minimum Death from military tuberculosis may be expected in a certain portion of cases of alternating pleurisy with effusion, irrespective of sanatorium treatment.^{1, 2}

SUMMARY AND CONCLUSIONS

Seven cases of alternating pleurisy with effusion, defined as the development of serofibrinous pleurisy occurring in the absence of pulmonary infiltration or only with suspicion of it and followed after a variable period of time by the development of contralateral serofibrinous pleurisy, are presented

The onset and course of each effusion associated with this syndrome differ in no way from that of the more frequent unilateral serofibrinous pleurisy

It is shown that alternating pleurisy with effusion may be a manifestation of tuberculosis

The proper treatment of pleurisy with effusion includes a prolonged sanatorium regimen

INTESTINAL OBSTRUCTION FOLLOWING ABDOMINAL BATTLE WOUNDS

LIEUTENANT COLONEL PHILIP S FOISIE, MC, AUS*

IN A previous paper,[†] the management of colostomies secondary to battle wounds of the abdomen has been discussed. Although most of these patients have done remarkably well during their definitive treatment at this general hospital, a few have shown complications that sometimes follow the damage caused by the passage of a ragged shell fragment through the abdomen. These cases should serve as a warning signal to the physicians under whose care such patients may later come.

The necessity of operating on a few of these soldiers has made us conscious of the potential danger of intestinal obstruction. We have been amazed at times that these patients have been able to maintain a functioning intestinal stream in spite of the amount of constriction and angulation of bowel that was found. In such patients particularly, early signs and symptoms suggesting the possible onset of obstruction must receive careful study and evaluation.

Anyone who reads the often penciled and sometimes blood-stained notes of the Field Medical Records is at once struck with the fact that some of these patients lived to reach a general hospital. These records frequently describe intestinal trauma of a severity foreboding almost certain death. The credit for such survivals belongs to the prompt and skillful surgical procedures of the forward medical installations, to the giving of plasma and blood by persons in this country and to the near-miracles of chemotherapy.

Factors that predispose to the formation of adhesions are multiple bowel perforations and lacerations of the bowel, particularly when these have resulted in considerable peritoneal soiling, hemorrhage, blast, lacerations of the mesentery, delay prior to initial surgery and infection. Since battle injuries may involve all these factors, it is not surprising that subsequent obstruction often results.

When some of these patients have been operated on for acute obstruction, an interesting phenomenon in the mechanism of the obstruction has been noted. In civil practice, intestinal obstruction is usually caused by some single discrete difficulty—a strangulated hernia, volvulus, intussusception or the like. The obstruction in these patients, however, is likely to occur partially at several points, with a gradual damming-up effect that increases to the final point of complete obstruction. This building-up of back pressure progresses in the reverse peristaltic direction toward the stomach, until at last so much distention occurs that the bowel becomes twisted or sharply angulated at a point of fixation and total obstruction results. The mechanism of

obstruction is therefore generally that of a series of obstructive points, no one of which is severe enough to cause total obstruction but that together produce a cumulative back pressure, with increasing stagnation of the intestinal stream, until complete obstruction ensues. With the usual obstruction from a single source, correction of the offending mechanism at the point where the bowel changes from distention to collapse solves the problem. In cases with the mechanism described above, on the other hand, the relief of the area of total obstruction frequently only leads one on to another point a few centimeters away distally at which highly questionable function is again encountered.

There is a constant danger in cases of this sort that an enthusiastic surgeon will do too much. The natural desire to free the bowel completely should be curbed, attention being confined to the few points at which some degree of definite obstruction has occurred. Inflamed, fibrin-covered bowel that has been freed is likely to form new adhesions, which may prove a greater hazard than those already freed. A totally obstructed patient should be subjected to as little trauma as will accomplish the goal of the operation—namely, re-establishment of the intestinal stream. Once the obstruction has been relieved, functioning bowel, even though densely adherent, should be left alone. More extensive lysis of adhesions may be attempted later, under more favorable conditions, if symptoms warrant.

Of the many substances that have been used to prevent reformation of adhesions, amniotic fluid has probably been the most successful. It was not available at this hospital, but may be of value in the subsequent treatment of these and similar cases in which further operative procedures are indicated. In several cases, the patients' condition halted mobilization of the bowel before it appeared certain that we had done all that was necessary, but their recovery justified this decision. In other words, a "let well enough alone" policy is applicable to these cases. In some of them we have been surprised on exploration to find with what severe matting together of the entire bowel patients had been able to maintain function until the acute obstructive episode occurred. In some cases, the bowel was so severely involved that complete freeing at a single operative procedure would have been impossible, but once the acute obstructive points were relieved these patients did well. They are, of course, liable to develop similar complications in the future, as are many others who have had intra-abdominal trauma but have so far been able to avoid difficulty. It is safe to predict that in veterans who have suffered abdominal wounds, acute intestinal obstruction will be encountered for many years to come.

*Instructor in surgery, Tufts College Medical School and assistant to visiting surgeons, Boston City Hospital (on leave of absence).

Five case histories will be cited to illustrate the surgical problem involved

CASE 1 A soldier was wounded in August, 1944, by high-explosive shell fragments, which blew out a large segment of the sacrum, tearing the rectum and causing multiple lacerations of the small bowel. He was operated on at an evacuation hospital through a long midline incision, and several defects in the ileum were repaired. Colostomy was not done at that time. He arrived at this hospital 2 weeks after his injury, at which time most of the feces were being evacuated through the sacral wound. The day after admission a Mikulicz colostomy was performed to divert the fecal stream from the wound. This effort was successful, and with irrigations the wound became clean and was completely healed in 8 weeks, during which time the patient's general condition improved.

The colostomy spur was then crushed and the colostomy was closed. Normal bowel movements followed these procedures, and the patient was apparently ready for evacuation when he developed a sudden and complete obstruction. This event was accompanied by such profound shock that several hours of resuscitative measures were required to prepare the patient for surgery. Under local anesthesia, the colostomy was reopened to ensure complete drainage of the lower bowel. This did not give relief, and after further supportive treatment the abdomen was reopened through a midline incision. Practically the entire bowel was found to be tangled in a mass of adhesions, with only the jejunum and the transverse and descending colon free. With a proximal approach, as much of the small bowel was freed as the patient's condition permitted. This soon proved to be futile, since several portions of the bowel were gangrenous. A catheter was sutured into the most distal point of free, viable small bowel, and the abdomen was closed. The prognosis was obviously hopeless.

At autopsy, performed 2 days later, the entire small bowel from the catheter onward was twisted in a gangrenous mass, which was firmly adherent to the pelvis and flank and also involved the ascending colon. The whole mass had to be resected to disentangle it completely.

Comment: This case, the only one in the present series that terminated fatally, demonstrated the extreme involvement of bowel that may occur.

CASE 2 The patient, a 20-year-old soldier, was wounded on November 12, 1944, by mortar-shell fragments, which caused multiple injuries, including penetration of the abdomen and multiple wounds of the small bowel. There was considerable inter-abdominal bleeding. At operation on November 22 at an evacuation hospital, the lacerated bowel was sutured. Colostomy was not done. Infection of the abdominal wound ensued.

On admission to this hospital on December 9, the patient was running a septic type of temperature and complained of pain in the right inguinal region. Chemotherapy and supportive treatment were used, pending a clearer indication for surgery, until December 13, when acute localized tenderness developed in the right lower quadrant of the abdomen, with definite muscle spasm. Laparotomy was performed on this date through the old wound, which was paper thin and was not completely healed. A diffuse fibrinous peritonitis was found, with free pus throughout the abdomen, multiple small walled-off abscesses and severe matting of the bowel by extensive adhesions. The abscess cavities were broken up, and drains were inserted through a stab wound into the pelvis. Although obstruction seemed unavoidable, the patient never developed any signs of it and became afebrile within 10 days. He was evacuated to the Zone of Interior on January 6, 1945, in good general condition.

Comment: This case, in which there was no actual obstruction, illustrates well the peritoneal difficulties that may follow abdominal battle wounds. There was every reason to expect obstruction, which demonstrates what extensive disease may be tolerated, with maintenance of intestinal flow, provided that the adhesions are innocuous. This patient is of course liable to have subsequent complications.

CASE 3 A 23-year-old soldier was wounded in Germany on December 7, 1944, by high-explosive shell fragments, which caused multiple wounds, including an abdomino-thoracic injury with severe right hemithorax, perforation of the right diaphragm and liver and considerable intra-

abdominal bleeding, but no bowel perforation. He was operated on at a field hospital on the day of the injury. The abdominal wound was closed after the evacuation of considerable blood, and drainage to the right subphrenic area was established through a stab wound in the flank. Thoracotomy was done, with repair of the rent in the right diaphragm.

The patient was admitted to this hospital on December 25 and appeared to be convalescing satisfactorily. On December 29, he developed sudden severe pain in the left lower quadrant of the abdomen and shortly presented signs of total intestinal obstruction. Laparotomy revealed multiple adhesions, which tied the bowel at several places, from the ilio-cecal valve through the distal third of the ileum to a point at which a loop of small bowel was anchored and twisted into a volvulus in the left lower quadrant. A loop of terminal ileum was firmly adherent at a point deep in the pelvis, and the freeing of this loop completely relieved the obstruction. The patient made an excellent recovery, in spite of being given doughnuts and coffee by a fellow patient on the 3rd postoperative day.

Comment: This case demonstrates the development of a total obstruction secondary to abdominal injury with no bowel perforation. The adhesions apparently developed from a retained blood clot.

CASE 4 The patient, a Negro soldier, sustained abdominal wounds, which had been treated at another general hospital for several weeks. On the way to the Zone of Interior, while lodged for the night at this hospital, he developed abdominal pain, distention, vomiting and acute localized tenderness and spasm. Obstruction was considered certain. Laparotomy disclosed the multiple-gradient type of obstruction described above, with the final point of total obstruction at a point in the left flank, to which a loop of twisted small bowel was securely fixed by a dense adhesion. Section of these adhesions gave complete relief.

CASE 5 A 28-year-old soldier was wounded on April 18, 1945, by a rifle bullet, which entered the right buttock and transversed the abdomen, making its exit through the left lower quadrant of the anterior wall. In its course the lower end of the right ureter was severed 3 cm above the vesical orifice. Two loops of small bowel were sufficiently injured to require resection and end-to-end anastomosis. There were also a compound fracture of the right ilium and extensive retroperitoneal hemorrhage.

The initial bowel repair was done at an evacuation hospital on the day of injury. The patient was subsequently treated at another general hospital, and was about to be evacuated to the Zone of Interior when the station hospital was ordered closed and he was transferred here to this hospital.

At admission on May 22, the patient presented a soft abdomen, with a nearly healed abdominal scar showing some evidence of recent infection. There was a urinary fistula through the right buttock.

One week after admission, colicky abdominal pain, with nausea, vomiting and increasing distention suddenly developed. Wangensteen suction gave no relief, and since the symptoms were rapidly progressing, operation was performed 3 hours after the onset of the acute attack. The old midline scar was excised, and when the abdomen was opened a generalized fibrinous peritonitis was found. This was most acute in the right lower quadrant, where multiple loops of bowel were matted together, apparently in an attempt to wall off urinary leakage from the severed ureter. The bowel, including the large bowel as far down as the sigmoid, was distended.

The adherent loops in the right lower quadrant were freed, a catheter was sutured into the cecum and brought out through a stab wound, and the wound was closed with heavy silk sutures without drainage. Ochsner treatment was instituted, with 40,000 units of penicillin in each infusion.

On the 10th postoperative day, the patient was doing well. The abdomen was soft, with no distention. Flatus was being expelled by rectum, and the temperature, pulse and respirations were normal. It was planned, as soon as the patient's condition permitted, to drain the kidney pelvis so as to remove the source of the peritonitis.

Comment: Although much of the distention was due to peritonitis, it seems probable that this patient had an acute obstruction due to the fact that the distended bowel was

INTESTINAL OBSTRUCTION FOLLOWING ABDOMINAL BATTLE WOUNDS

LIEUTENANT COLONEL PHILIP S FOISIE, MC, A.US *

IN A previous paper,[†] the management of colostomies secondary to battle wounds of the abdomen has been discussed. Although most of these patients have done remarkably well during their definitive treatment at this general hospital, a few have shown complications that sometimes follow the damage caused by the passage of a ragged shell fragment through the abdomen. These cases should serve as a warning signal to the physicians under whose care such patients may later come.

The necessity of operating on a few of these soldiers has made us conscious of the potential danger of intestinal obstruction. We have been amazed at times that these patients have been able to maintain a functioning intestinal stream in spite of the amount of constriction and angulation of bowel that was found. In such patients particularly, early signs and symptoms suggesting the possible onset of obstruction must receive careful study and evaluation.

Anyone who reads the often penciled and sometimes blood-stained notes of the Field Medical Records is at once struck with the fact that some of these patients lived to reach a general hospital. These records frequently describe intestinal trauma of a severity foreboding almost certain death. The credit for such survivals belongs to the prompt and skillful surgical procedures of the forward medical installations, to the giving of plasma and blood by persons in this country and to the near-miracles of chemotherapy.

Factors that predispose to the formation of adhesions are multiple bowel perforations and lacerations of the bowel, particularly when these have resulted in considerable peritoneal soiling, hemorrhage, blast, lacerations of the mesentery, delay prior to initial surgery and infection. Since battle injuries may involve all these factors, it is not surprising that subsequent obstruction often results.

When some of these patients have been operated on for acute obstruction, an interesting phenomenon in the mechanism of the obstruction has been noted. In civil practice, intestinal obstruction is usually caused by some single discrete difficulty—a strangulated hernia, volvulus, intussusception or the like. The obstruction in these patients, however, is likely to occur partially at several points, with a gradual damming-up effect that increases to the final point of complete obstruction. This building-up of back pressure progresses in the reverse peristaltic direction toward the stomach, until at last so much distention occurs that the bowel becomes twisted or sharply angulated at a point of fixation and total obstruction results. The mechanism of

obstruction is therefore generally that of a series of obstructive points, no one of which is severe enough to cause total obstruction but that together produce a cumulative back pressure, with increasing stagnation of the intestinal stream, until complete obstruction ensues. With the usual obstruction from a single source, correction of the offending mechanism at the point where the bowel changes from distention to collapse solves the problem. In cases with the mechanism described above, on the other hand, the relief of the area of total obstruction frequently only leads one on to another point a few centimeters away distally at which highly questionable function is again encountered.

There is a constant danger in cases of this sort that an enthusiastic surgeon will do too much. The natural desire to free the bowel completely should be curbed, attention being confined to the few points at which some degree of definite obstruction has occurred. Inflamed, fibrin-covered bowel that has been freed is likely to form new adhesions, which may prove a greater hazard than those already freed. A totally obstructed patient should be subjected to as little trauma as will accomplish the goal of the operation—namely, re-establishment of the intestinal stream. Once the obstruction has been relieved, functioning bowel, even though densely adherent, should be left alone. More extensive lysis of adhesions may be attempted later, under more favorable conditions, if symptoms warrant.

Of the many substances that have been used to prevent reformation of adhesions, amniotic fluid has probably been the most successful. It was not available at this hospital, but may be of value in the subsequent treatment of these and similar cases in which further operative procedures are indicated. In several cases, the patients' condition halted mobilization of the bowel before it appeared certain that we had done all that was necessary, but their recovery justified this decision. In other words, a "let well enough alone" policy is applicable to these cases. In some of them we have been surprised on exploration to find with what severe matting together of the entire bowel patients had been able to maintain function until the acute obstructive episode occurred. In some cases, the bowel was so severely involved that complete freeing at a single operative procedure would have been impossible, but once the acute obstructive points were relieved these patients did well. They are, of course, liable to develop similar complications in the future, as are many others who have had intra-abdominal trauma but have so far been able to avoid difficulty. It is safe to predict that in veterans who have suffered abdominal wounds, acute intestinal obstruction will be encountered for many years to come.

fluid protein. Accordingly, the patient was thought to have an associated diabetic neuritis. His course had been essentially uneventful, however, and he was discharged on a dosage of 40 units of protamine-zinc insulin and a diet consisting of 129 gm. of carbohydrate, 69 gm. of protein and 76 gm. of fat.

The patient was regularly followed in the Diabetes Clinic for the next 3 years. He then disappeared for 3 years, reappearing in the Emergency Ward in April, 1943, with severe diabetic acidosis, precipitated by a throat infection. The blood sugar was 434 mg. per 100 cc., the carbon dioxide content 18.5 millimols per liter, and the blood nonprotein nitrogen 64 mg. per 100 cc. He was given 388 units of crystalline insulin (124 units intravenously), 4500 cc. of 5 per cent dextrose in normal saline solution and 15 gm. of sodium bicarbonate. The acidosis responded well, but the patient ran a stormy course and developed severe respiratory distress, which necessitated an emergency tracheotomy on April 28, 1943. He was later found by x-ray to have complete laryngeal obstruction. Throat cultures showed a hemolytic *Staphylococcus aureus* to be predominating, and he was therefore given sulfadiazine for 2 weeks. Since the tracheotomy incision could not be closed because of the laryngeal obstruction, he was discharged on June 22 with the tube in place. The insulin requirement at that time was 30 units of protamine-zinc insulin and 10 units of crystalline insulin every morning, with occasional extra crystalline insulin by test.

In the following November, the patient was readmitted for widening of the tracheotomy. Three operations were later performed in an unsuccessful attempt to close the tracheotomy permanently. At that time it was extremely difficult to regulate the diabetes. The patient was discharged on a dosage of 40 units of globin insulin and a diet of 225 gm. of carbohydrates, 85 gm. of protein and 90 gm. of fat.

Throughout the next year, he appeared at irregular intervals in the Diabetes Clinic and was seen there on August 4, at which time the urine showed an orange color on a Benedict test.

The patient's living conditions had been extremely poor. He lived alone and prepared his own meals, living chiefly on canned foods and paying little attention to the prescribed diet. He was unwilling to work at his former trade of weaving because the tracheotomy made him self-conscious, and his sole interest in life was to return to the hospital to have it repaired. As months went by without word of an appointment, he became more and more depressed and lost the desire to live. He denied alcoholic indulgence during this time, but admitted almost complete neglect of his diabetes treatment.

The fifth admission occurred on January 3, 1945, when the patient was brought to the Emergency Ward by ambulance in a semicomatose condition. Two days previously he had developed abdominal pain, nausea, vomiting and diarrhea. He had been taking insulin—80 units of globin insulin—"fairly regularly" but had not tested his urine for some weeks. The diet had consisted largely of canned foods in irregular amounts. The night before admission he called a physician, who suspected an impending diabetic coma but gave no extra insulin. On the morning of admission, in addition to the symptoms listed, the patient had suddenly become deaf and was unable to hear unless one shouted directly into either ear.

The physical examination revealed a thin, pale and semicomatose patient. The skin and tongue were dry. The eyeballs were soft. The breath smelled of acetone. The patient could be aroused only with difficulty and spoke in a hoarse voice when he closed the tracheotomy tube. There were a few coarse rales at both lung bases, but no abnormal breath sounds. The heart was not enlarged. The rhythm was totally irregular, and the heart sounds were of poor quality. No murmurs were heard. The abdomen was soft, but there was generalized tenderness without rebound or spasm. The liver, spleen and kidneys were not felt. Deep-tendon reflexes were absent on admission.

The temperature was 95.8°F, the pulse 140, the respirations 40 (Kussman's), and the blood pressure 80/50.

The urine gave a brick-red test for sugar and +++ tests for acetone and diacetic acid and contained a slight trace of albumin. Its specific gravity was 1.022. The hemoglobin was 12.7 gm. per 100 cc., the red-cell count 4,300,000, and the white-cell count 22,700. The blood-sugar level was 1240 mg. per 100 cc. and the carbon dioxide was 3.8 millimols per liter. The nonprotein nitrogen was 108 mg. per 100 cc.,

the chlorides 76 milliequiv. per liter, and the total protein 8.2 gm. per 100 cc.

Therapy was started immediately with 1500 cc. of normal saline solution intravenously, 100 units of crystalline insulin—50 units intravenously and 50 subcutaneously—and 15 gm. of sodium bicarbonate. The stomach was aspirated, but no fluid was obtained. This was a rather hazardous procedure, and the patient struggled against it so much that he became cyanotic owing to improper functioning of the tracheotomy tube. An indwelling catheter was inserted shortly after admission, and 1000 cc. of urine was obtained. A second infusion was started with 250 cc. of blood plasma in saline. When the blood chemical findings became available 1½ hours after admission the insulin dosage was increased to 100 or 200 units intravenously and 100 or 200 units subcutaneously hourly, thus during the first 3 hours the patient received a total of 720 units. Despite the giving of constant intravenous saline solution with alkali, he remained anuric for 6 hours. Accordingly, blood chemical analyses were checked at hourly intervals. After an initial fall from 1240 mg. per 100 cc. to 928 mg., the blood-sugar level remained at approximately 900 mg. for 4 hours, necessitating constantly increasing doses of insulin. At 2:30 p.m., 4 hours after admission, the patient became extremely cyanotic and dyspneic. The pulse could not be obtained, and the respirations ceased. Oxygen and artificial respiration were given, and 3 cc. of a 25 per cent solution of Coramine and 0.5 gm. of caffeine sodium benzoate were injected intravenously, after which the respirations and pulse returned. The insulin dosage was increased to 200 units every half hour—100 units intravenously and 100 subcutaneously—in a desperate attempt to lower the blood sugar and correct the ketosis. At 4:30 p.m. an increase in the number of rales in the lungs was noted, and in view of the auricular fibrillation, which was confirmed by electrocardiogram, digitalization was begun at once with 6 cc. (12 mg.) of Cedilanid intravenously. Shortly after this, 5 cc. of urine was obtained. In an attempt to produce a diuresis, 20 cc. of a 10 per cent solution of serum was given at 5:10 p.m. Thereafter the patient's condition steadily improved, the insulin dosage was lowered, and at 4 a.m., 18 hours after admission, the blood sugar was 119 mg. per 100 cc., the carbon dioxide 37.1 millimols per liter, the nonprotein nitrogen 72 mg. per 100 cc., and the chloride 95 milliequiv. per liter. The last dose of insulin (50 units) was given at 3 a.m. At 6:30 a.m. there was a mild insulin reaction, with the blood sugar 35 mg. per 100 cc., which was relieved by 50 cc. of 50 per cent glucose intravenously. The summary of therapy during the first 20 hours is given in Table 1. The

TABLE 1 Summary of Therapy Given During the First Twenty Hours

SUBSTANCE	QUANTITY
Crystalline insulin	3620 units (¾ intravenously, ¾ subcutaneously)
Normal saline solution	7000 cc. (intravenously)
Sodium bicarbonate	52.5 gm. (intravenously)
Blood plasma	1500 cc. (intravenously)
Whole blood	250 cc. (intravenously)
Cedilanid (Lanatonide C)	16 mg. (intravenously)
Coramine	0.75 gm. (intravenously)
Caffeine sodium benzoate	0.5 gm. (intravenously)
10% saline solution	20 cc. (intravenously)
Broth and fruit juice	800 cc. (orally)

total fluid intake during the first 20 hours was 9630 cc., and the output was 2035 cc., exclusive of the 1000 cc. obtained when the patient was catheterized shortly after entry.

On the following day, the patient continued to complain of abdominal pain and was unable to eat. He was fed by intravenous fluids and required only 40 units of insulin throughout the day. The hearing had returned to normal. The heart rhythm had also returned to normal,—this was confirmed by electrocardiogram,—and it was thought that digitalis was no longer necessary. Blood-sugar samples taken throughout the day varied between 52 and 171 mg. per 100 cc., and the carbon dioxide had begun to return to normal (Table 2).

The abdominal pain persisted for 4 days, but on January 7 the patient was able to eat and an attempt to regulate the diabetes was begun. This proved to be quite difficult, and various combinations of protamine-zinc, crystalline and

caught in adhesions in the right lower quadrant, secondary to urinary leakage

SUMMARY

Abdominal battle injuries are likely to produce extensive adhesions that pave the way for subsequent obstruction. Such patients may do well for varying periods, but a serious hazard persists, and obstructive episodes will probably be encoun-

tered for years to come. Early signs and symptoms should receive careful evaluation and close watching.

A graduated obstructive mechanism is described. With acute obstruction only the offending mechanism should be freed. Interval lysis with the instillation of amniotic fluid may be advisable when chronic symptoms suggest impending difficulty. Five illustrative cases of acute intestinal obstruction, with 1 death, are reported.

SUCCESSFUL TREATMENT OF SEVERE DIABETIC COMA COMPLICATED BY CHRONIC LARYNGEAL OBSTRUCTION*

Report of a Case

ROSEMARY V. GORMAN, M.D.,† REED HARWOOD, M.D.,‡ AND PAUL D. WHITE, M.D.§

BOSTON

THE association of severe diabetic coma and chronic laryngeal obstruction is rare. The case reported herein presented these two problems, and in addition a third, a severe mental depression following tracheotomy that induced the patient to neglect the treatment of his diabetes. Although his immediate survival depended on recovery from the coma, his return to life as a useful citizen awaited the repair of the tracheotomy. In the treatment of the coma, the largest amount of insulin ever reported to have been given in twenty hours was administered. Three delicate plastic operations were performed to repair the tracheotomy. Our experience with such a patient is worth recounting, in the hope that it may be a means of rescuing others from death or despondency.

There are many reports in the medical literature of extreme hyperglycemia requiring tremendous doses of insulin. These cases can be divided into two groups. In the first, hyperglycemia is usually associated with coma and its cause is evident — infection, hepatic disease, endocrine disorder or neglect of insulin therapy or diet. The acidosis is controlled by large doses of insulin, and the patient usually returns to his precoma status. In the second group, in which also the condition may be associated with coma, there is no explanation for the obstinate hyperglycemia, and the need for excessive doses of insulin continues for weeks or even months. This group is composed of patients who may be called insulin-resistant. It will not be further discussed here.

The case reported presents several unusual features. The coma was precipitated by infection and neglect of insulin therapy. The infection was apparently a severe, nonspecific gastroenteritis. The

patient received 3620 units of insulin in twenty hours. In Wiener's¹ case the patient required 3250 units of insulin in the emergency, but the case differed from the present one in his continued need for large doses of insulin. In a case reported by Glass, Spingarn and Pollack,² the patient required 85,000 units over a five-and-a-half-month period and the maximum twenty-four-hour dose was 2795 units. It is interesting that the excessive insulin need subsided six months after its onset. The greatest daily quantity of insulin given at the New England Deaconess Hospital has been 2272 units in the case of a man who had diabetic coma during a phase of insulin resistance.³ Many cases, however, have been reported in which the initial blood-sugar levels exceeded that of 1240 mg. per 100 cc. in the present case. The highest value recorded is 2060 mg.⁴ Dillon and Dyer⁵ reported the highest blood-sugar level (1850 mg.) recorded in a patient who survived.

CASE REPORT

C. D., a 34-year-old man, a native of Massachusetts, was admitted to the Massachusetts General Hospital for the fifth time on January 3, 1945, semicomatose and in severe diabetic acidosis.

The patient was first admitted to this hospital on April 10, 1929, for regulation of his diabetes, which had been discovered in 1924, when he was 14 years old. In 1925, his physician had started him on insulin, gradually increasing the dose and varying the diet to suit the patient's needs. He did not co-operate well and was therefore hospitalized. After 10 days of study, he was discharged on a diet consisting of 120 gm. of carbohydrate, 180 gm. of protein and 100 gm. of fat and a dosage of 50 units of insulin (20-20-10).

He did well thereafter until 1935, when he was readmitted to the Orthopedic Service with a fracture of the right tibia and fibula and phenobarbital poisoning. At this time the diabetes was slightly more difficult to control, and the patient was discharged on a dosage of 51 units of crystalline insulin (25-5-15-6) and a diet consisting of 160 gm. of carbohydrate, 92 gm. of protein and 101 gm. of fat.

The third admission occurred in 1936, and was for tonsillectomy and diabetic regulation on protamine-zinc insulin. There had been some abnormal neurologic findings, — sluggish knee and ankle jerks and equivocal plantar responses, — and lumbar puncture revealed an elevated spinal

desire for life after recovery At first it was suggested that the patient's condition presented too great a risk or at least promised too short a survival time to warrant the hazard, but the reverse seemed likelier to be true — namely, that the repair of the air passages would make life again worth living, and hence that so far as the diabetes, and with it the patient's longevity, was concerned, the risk of not operating would actually be greater than the risk of operating This prophecy has so far proved to be correct

SUMMARY

The case is reported of a man of thirty-four in diabetic coma who required for recovery 3620 units

repair the air passages were carried out to rehabilitate him after recovery from diabetic coma This has undoubtedly been as important in aiding the patient's longevity as was the immediate treatment of the diabetic coma

globin insulin were tried. The disease was finally under fairly good control with 35 units of protamine-zinc insulin every morning. On this dosage the urine varied between green, with sediment, and blue, the fasting blood sugar was 105 mg per 100 cc on one occasion and 152 mg on another.

On February 16, 45 days after admission, the patient was transferred to the Massachusetts Eye and Ear Infirmary for a plastic operation on the trachea, in an attempt to close the tracheotomy and thus remove the factor responsible for the mental depression. Two operations were performed in the preparation of skin flaps on the right and left sides of the neck. In the right-hand flap several strips of cartilage were embedded to give added support to the trachea. The tube was left in place, and on April 7 the patient was discharged.

hospital. Deafness was an unusual complication of the coma and could not be explained. No reference to this concomitant appears in the literature. Another unusual feature was the occurrence of auricular fibrillation, which so far as we know has been reported in only 1 other case of diabetic coma.³ In both cases the fibrillation was transient and recovery from the coma was complete.

It has been suggested, on review of the data, that this patient was overtreated. This is admitted, but

home on a dosage of 30 units of protamine-zinc insulin and 15 units of globin insulin every morning and a diet of 300 gm of carbohydrates, 100 gm of protein and 80 gm of fat.

On June 2, the patient was readmitted to the Eye and Ear Infirmary, where the tracheotomy was successfully closed at a third operation by incising around the edges of the opening and suturing them over it, and swinging the previously prepared delayed flap from the right side of the neck over the tracheotomy.* No change was made in the satisfactory program used for the regulation of the diabetes, and on June 20 the patient was discharged asymptomatic and in good spirits.

DISCUSSION

This patient had a severer diabetic acidosis and required more insulin in the first twenty-four hours than has any other patient ever treated in this

with qualification. The insulin dosage was large but not excessive. If larger doses had been given early the total dose required might have been smaller. Doubtless larger doses should have been administered at once, even before the blood analysis was reported. The dosage of sodium bicarbonate was perhaps excessive, but it caused no irreversible changes. The fluid intake, in view of his severe dehydration and nausea, was not excessive. The question of whether the blood and plasma were necessary is one of pure speculation. The patient's condition was such that they could not well have been omitted. Likewise, the oxygen, Coramine, caffeine, Cedilanid and hypertonic saline solution were given under definite indications. Each of

*These operations will be described in detail in a later publication by Dr. V. H. Kazanjian to whom we are indebted for this account.

the point of an experimental coarctation of the aorta. Since the operation to be described was devised to compensate for an inadequate flow of blood to the lungs, it seemed desirable that the anastomosis be made in such a manner that the blood from the systemic artery would be enabled to reach both lungs. Suture anastomosis could not be made to the main pulmonary artery, since occlusion of this vessel for more than a few minutes causes death. It therefore appeared that the anastomosis should be made just distal to the division of the main pulmonary artery and, furthermore, that the side of the chosen vessel should be used so that the blood might flow to both lungs.

With such an extensive clinical and experimental background, briefly summarized above, Blalock operated successfully on 3 patients, all of them children, who had a clinical diagnosis of tetralogy of Fallot with a severe degree of pulmonary stenosis. There were slight variations in each of the operations, but the following abbreviated description summarizes the major features.

Under light general anesthesia, an anterior transpleural approach was made on the right or left side, depending on the position of the great vessels and the artery to be used in the anastomosis. The right or left pulmonary artery was exposed and dissected from the adjacent tissues for as great a distance as possible. The subclavian or innominate artery was dissected free of the adjacent tissues, and by the use of a bulldog arterial clamp the vessel chosen was occluded temporarily at the point at which it arose from the aorta. In the case of the innominate artery, its branches were ligated at their origins and it was cut across just proximal to the ligatures. A bulldog arterial clamp was placed on the right or left pulmonary artery just distal to the point of division of the main pulmonary artery. A second clamp was placed on the right or left pulmonary artery just proximal to the point where the vessel gave off a branch to the upper lobe of the lung. A transverse opening was made into the side of the pulmonary artery midway between the two clamps. The anastomosis between the end of the systemic artery and the side of the pulmonary artery was then carried out, with a meticulous technic and with the employment of fine silk on a curved needle as suture material. The bulldog clamps were removed from the pulmonary artery, and this was followed by removal of the clamp from the systemic vessel. The lung was re-expanded, and the incision in the chest wall was closed.

Each of the 3 patients suffered from such a severe degree of pulmonary stenosis that there was inadequate circulation to the lungs. Although the three operations differed in detail, in each case the procedure greatly increased the volume of blood that reached the lungs.

Fear that an intensely cyanotic patient would not tolerate a long operative procedure in which

it was necessary to open the pleural cavity and to occlude temporarily one of the pulmonary arteries proved unfounded. Fortunately, the administration of oxygen during anesthesia increased the oxygen content of the arterial blood, and cyanosis was definitely lessened. The question whether a patient already severely anoxic would tolerate the occlusion of one of the main pulmonary arteries for the period necessary in performing the anastomosis appears to have been answered satisfactorily. The 3 patients tolerated occlusion of the left or right main pulmonary artery for periods of thirty to ninety minutes.

Another question that arose was whether ligation and division of the left subclavian artery or the innominate artery would result in serious impairment of the circulation to the arm and brain. Blalock and Taussig were gratified to note that there was little evidence of impairment of circulation to the parts deprived of their major arterial pathway. The pulse was absent for some time postoperatively, and the part was slightly cooler than the corresponding one on the opposite side of the body, but immediately after operation it was evident that the circulation was adequate to maintain life in the part. The advisability of performing upper dorsal sympathectomy at the time of operation, which does not add to the burden of operation, is suggested by the authors.

Blalock and Taussig state that the degree of impairment in the flow of blood to the lungs varies from patient to patient and that the selection of the vessel to be used depends on the extent of the need of the patient for an increase in the circulation to the lungs. The size of the vessel chosen and of the anastomosis itself should not be larger than is necessary for the relief of anoxemia, because of the danger associated with excessive shunting of blood to the lungs.

A discussion of other methods by which an anastomosis between the systemic and pulmonary circulations may be made includes a simple and rapid method that Blalock and his associates^{3, 4} have carried out in experimental animals. The first portions of the medial walls of the aorta and the pulmonary artery, which are intimately adherent to each other, are contained within the pericardial cavity and are enclosed in a tube of serous pericardium common to the two vessels. They were able to produce a fistula between the two vessels in dogs by inflicting a stab wound in this region. The knife blade was introduced through the opposite free wall of the pulmonary artery, the walls of the pulmonary artery and aorta, which were in intimate contact, were pierced, the knife was withdrawn, and the opening in the free side of the pulmonary artery was closed by sutures. The establishment of the fistula required only a few seconds. The method is mentioned because it may be necessary to use the major blood vessels and to employ considerable speed if

MEDICAL PROGRESS

SURGERY OF THE HEART AND STRUCTURES RELATED TO IT

JOHN W. STRIEDER, M.D.*

BOSTON

SURGERY of the heart and structures related to it will be considered under five main headings — congenital lesions, trauma, acute pericarditis, constrictive pericarditis and miscellaneous conditions

CONGENITAL LESIONS

Pulmonary Stenosis or Pulmonary Atresia

Blalock and Taussig¹ have recently reported and discussed 3 cases in which children with severe degrees of pulmonary stenosis were operated on successfully and with apparent benefit. Heretofore, there has been no satisfactory treatment for pulmonary stenosis or pulmonary atresia. A so-called "blue baby" with a malformed heart was considered beyond the reach of surgical aid. These authors in undertaking the operation were convinced that even though the structure of the heart was grossly abnormal, it might be possible in many cases to alter the course of the circulation in such a manner as to lessen the cyanosis and the resultant disability. They emphasize the fact that it is not the cyanosis per se that does harm.

In the development of this thesis, the studies of Lundsgaard and Van Slyke² on the causes of cyanosis are cited. These studies demonstrated the great significance of pulmonary factors. The extent of the oxygenation of the blood in the lungs clearly depends on the vital capacity of the patient, the rate of flow of blood through the lungs, the partial pressure of the oxygen in the inspired air and a specific pulmonary factor that is designated as the "alpha factor." In most, if not all, cases in which there was a pronounced polycythemia, there were secondary changes in the lungs of such a nature that all the blood that passed through them was no longer in effective contact with the oxygen in the alveoli. The fact that all the blood that circulated through the lungs was not fully oxygenated made it seem improbable that if more blood had circulated through the lungs a larger proportion of it would have been oxygenated. Blalock and Taussig believe that this demonstration of the alpha factor completely overshadows another vitally important factor — namely, the volume of blood that reaches the lungs for aeration.

Expressed in the simplest terms, the circulation of the blood through the lungs after birth is essential for life, anyone deprived of such circulation dies. For example, in all cases of pulmonary atresia in which the circulation to the lungs is by way of the

ductus arteriosus, the closure of the latter renders the condition incompatible with life.

Blalock and Taussig then discuss a variety of congenital malformations that illustrate the importance of the volume of the pulmonary circulation in the production of cyanosis. One of these is the malformation consisting of a single ventricle with a rudimentary outlet chamber. If the great vessels occupy their normal positions, the aorta arises from the common ventricle and is of large caliber, whereas the pulmonary artery arises from the rudimentary outlet chamber and is of small caliber. As a result, a large volume of blood goes to the systemic circulation and only a small volume of blood goes to the lung, and there is intense cyanosis. If the great vessels are transposed and the pulmonary artery is large and the aorta is small, a large volume of blood goes to the lungs for aeration, and cyanosis is minimal or absent.

Another case in point is that of truncus arteriosus. When the pulmonary arteries arise directly from the aorta, there is adequate circulation to the lungs, and cyanosis is minimal or absent. If, however, the pulmonary artery fails to arise from the heart or to connect with the aorta and the circulation to the lungs is by way of the bronchial arteries, only a small volume of blood reaches the lungs for aeration, and cyanosis is intense.

As a result of these and other observations, these authors conclude that many gross malformations of the heart are compatible with life provided there is adequate circulation to the lungs and, furthermore, that lack of circulation to the lungs is the primary cause of death in many infants with congenital malformation of the heart. An appreciation of these facts, together with an extensive previous experience with the experimental use of large arteries for the purpose of conducting blood to sites not usually supplied by such vessels, led to the development of an operation for increasing the flow of blood through the lungs in patients with congenital malformations of the heart. The operation consists in making an anastomosis between a branch of the aorta and one of the pulmonary arteries, — in other words, the creation of an artificial ductus arteriosus.

Levy and Blalock³ have demonstrated the feasibility of anastomosing a systemic artery to one of the pulmonary arteries in experimental animals. Blalock and Park⁴ have reported the suturing of the severed proximal end of the subclavian artery to the aorta as a means of conducting blood beyond

*Visiting surgeon in charge of thoracic surgery, Massachusetts Memorial Hospitals and Boston City Hospital; assistant professor of thoracic surgery, Boston University School of Medicine.

was undertaken. The aorta was ligated with 13 cm-wide cotton tape just below the left subclavian artery and 4 cm below the aneurysm. The divided ends of the aorta were oversewn with silk.

The convalescence was uneventful until the seventeenth day, when acute cardiac decompensation occurred. This was treated satisfactorily with oxygen, morphine, venesection, digitalization, mercupurin and ammonium chloride. The patient was discharged on the thirty-sixth postoperative day.

The pathogenesis of the aneurysm was not definitely established, but the authors consider it necessary to assume the presence of a coarctation to explain the remarkably well developed collateral circulation, the bilateral rib notching and the absence of pulsation of the aneurysm and of the aorta below it.

The success of this operation was attendant on a happy combination of circumstances, and it is extremely unlikely that this combination will again be encountered. As the authors point out, this case was unique in that all the factors essential to the success of the operation were present — youth and general good health, the absence of syphilitic disease of the aorta, the presence of a well established collateral circulation and the favorable location of the aneurysm, which permitted the placing of the proximal ligature on the aorta below the left subclavian artery.

The authors also emphasize that the success in their case has no bearing on the management of aneurysm in general.

Patent Ductus Arteriosus

The literature on patent ductus arteriosus continues to increase, and as might be expected with the availability of larger series of cases that have been treated by ligation, certain authors have attempted to determine the need for surgery in these cases. Shapiro and Keys⁸ discuss a clinical series of 51 cases and analyze operations undertaken for ligation of the patent ductus in 140 cases. During their years of observation, they have been led to consider the lesion an apparently harmless one. Children have gone through school, young men have done hard labor and women have borne children, all with no evidence of cardiac disability. On the basis of these observations, one may readily assume an attitude of conservatism. Analysis of the world literature, however, showed that 80 per cent of patients eventually die from their cardiac lesion. Those who were alive at seventeen years of age averaged thirty-five years at death. At least 40 per cent of these patients died of subacute bacterial endarteritis, and most of the remainder died of congestive heart failure. The average age of the authors' series of 51 patients was less than twenty-five years, and the oldest patient died at fifty-eight. These data force reconsideration of a conservative attitude toward what might seem radical surgery.

The authors conclude that surgery is advisable for most patients with patent ductus arteriosus, with or without subacute bacterial endarteritis. Ligation should be attempted immediately once a diagnosis of subacute bacterial endarteritis has been made.

Burch⁹ states that ligation should be done if there is associated endarteritis, and also if there is progressive cardiac damage and decompensation or definite impairment of mental and physical development. He reviewed most of the reported cases of surgical ligation and found the mean mortality rate to be 85 per cent in uninfected cases. Burch believes that in the future the operation will probably be recommended as soon as a patent ductus is discovered, but in view of the mortality no such recommendation can be made now. Poor results following ligation, he states, may be attributed to failure to find the ductus, ligation of the wrong vessel, wound sepsis, hemorrhage, associated cardiovascular abnormalities and incomplete obliteration of the ductus.

Such a reactionary attitude does not seem fully justified. The operation is still technically in its developmental stage, and most thoracic surgeons are of the opinion that a considerable reduction in the operative mortality is by no means beyond achievement. Of course, only time will tell how ligation will affect the life span.

The effect of ligation on infection of a patent ductus has been dramatic, and infection must now be considered an urgent indication for operation. Tubbs¹⁰ describes 9 cases of subacute bacterial endarteritis complicating this anomaly and treated by ligation. Six of the patients were well fifteen months to four years after operation. He stresses the importance of the early diagnosis of the super-vention of infection so that ligation may be undertaken at the optimum time, before the infection has had an opportunity to render the ductus friable and the adjacent tissues edematous.

Bettman and Tannenbaum¹¹ report the successful ligation of a patent ductus complicated by bacterial endocarditis in a woman eighteen years old. She made a good recovery and was well two years after operation. Harper and Robinson¹² treated a similar case in a woman of twenty-eight who had long-standing severe subacute bacterial endocarditis. The ductus was ligated with two silk ligatures, and cellophane was wrapped loosely about it. These authors believe that the cellophane was responsible for the final complete occlusion of the ductus. The murmur and symptoms disappeared for two weeks, but reappeared and persisted for two and a half months after operation. The murmur and symptoms then completely disappeared, and the patient remained entirely well for one and a half years after surgery. The final, complete and permanent occlusion of the patent ductus arteriosus was thought to have been brought

newborn infants with pulmonary stenosis or atresia are to be saved

As to indications, Blalock and Taussig are of the opinion that the types of abnormalities that should be benefited by the operation described are the tetralogy of Fallot and pulmonary atresia, with or without dextroposition of the aorta and with or without defective development of the right ventricle. Other abnormalities likely to be benefited are a truncus arteriosus with bronchial arteries and a single ventricle with a rudimentary outlet chamber in which the pulmonary artery is diminutive in size. The operation is indicated only when there is clinical and radiologic evidence of a decrease in the pulmonary blood flow.

They believe that the operation is not indicated in cases of complete transposition of the great vessels or in the tetralogy of Fallot of so-called "Eisenmenger type," and probably not in aortic atresia. It should not be performed when studies reveal a prominent pulmonary conus or pulsations at the hilum of the lungs.

COARCTATION OF THE AORTA

Crafoord and Nylin⁶ have recently reported 2 cases of coarctation of the aorta that were cured by surgical means. Apparently these operations, which were performed in October, 1944, are the first successful ones to be done for this lesion in man. Blalock and Park,⁴ however, had already described a method of by-passing the coarctation, which they had carried out successfully in experimental animals.

Because Crafoord had demonstrated that the flow of blood to all the organs could remain suspended for as long as twenty to twenty-five minutes without subsequent signs of organic damage, provided there was an adequate flow of blood to the brain, he took the risk of placing clamps on the aorta above and below the patent ductus arteriosus and left them in place during the time necessary to divide the ductus and suture the aorta. In one patient the aorta was thus occluded just below the origin of the left subclavian artery for twenty-seven minutes without noticeable subsequent disturbances of organs. It was on the basis of this experience in patients with patent ductus arteriosus that Crafoord conceived his operation for coarctation of the aorta, and because of the relatively bad prognosis in these cases he felt justified in making an attempt at surgical treatment. Excerpts from Crafoord's description of his operation follow:

In both patients, the aorta showed conical narrowing from the origin of the subclavian artery, and the conical constriction between the coarctation and the point of departure of the subclavian artery was much longer in the first case [a small boy] than in the second. Clamp forceps were then attached to the aorta just below the point of origin of the subclavian artery, as well as at a point as far away as possible from the first pair of aortic intercostal arteries. Small clamp forceps were then placed on all the branches arising from the aorta between the two forceps on the main trunk of the aorta. Resection

of the aorta, taking in the most constricted segment was then carried out. On the peripheral side, the incision through the aorta was made in a plane at right angles to the long axis of the aorta, 2 mm proximal to the point of origin of the first pair of intercostal arteries. Centrally, the place of incision was placed at an angle of about 45° in relation to the long axis of the aorta, owing to the fact that the lumen here was narrower than on the peripheral aspect, and about 1 cm away from the area of greatest constriction. In this way, two lumens with circumferences to fit one another were obtained. A typical Carrel aorta suture was then made. First, three interrupted sutures were placed at equal distances from each other, and then running silk sutures were sewn between the interrupted sutures, each stitch being drawn up separately to secure adequate tautness.

When the forceps were removed, it was found that an ideal artery suture with no leaks had been achieved.

The patients were both in excellent health when examined in March, 1945.

Crafoord and Nylin consider it remarkable that in both cases normal conditions as regards the blood pressure were re-established. In both the blood pressure in the legs was a little higher than that in the arms, and no true hypertension was present. They believe that this postoperative effect is in favor of the mechanical theory of hypertension in coarctation.

Working independently, Gross and Hufnagel⁶ evolved an almost identical technic on dogs, and operated on two patients in June and July, 1945. The first patient, a six-year-old child, died when the clamps were removed from the aorta, the heart going into uncontrollable dilatation as the result of the sudden opening of the enormous vascular bed. The second patient, a twelve-year-old girl, survived the operation and was discharged in a satisfactory condition on the nineteenth postoperative day. In this case the clamps were gradually released over a ten-minute period. In view of their experience in their first case, the authors stress the importance of the slow removal of the aortic clamps.

Alexander and Byron⁷ report the successful removal of an aneurysm of the thoracic aorta. This is apparently the first time that an aneurysm of the thoracic or abdominal aorta has been successfully removed or that the thoracic aorta has been successfully ligated. The patient, a nineteen-year-old student, showed a nonpulsating mass in the left side of the mediastinum, mild hypertension and a well established collateral circulation. A provisional diagnosis of aortic coarctation on the basis of extrinsic pressure by a neoplasm—probably a neurofibroma—was made, and thoracotomy was performed. At operation a thin-walled saccular aneurysm of the upper descending aorta was exposed in the costovertebral gutter. Its upper pole was 5 cm inferior to the left subclavian artery, and its attachment to the aorta was 7.5 cm long. The aorta appeared to be slightly constricted at its junction with the upper end of the aneurysm. Since the thin-walled aneurysm was in danger of rupture and since the collateral circulation appeared to be adequate, resection of the aneurysm

lower liver margin centrally, where the dye was not absorbed. The liver abscess was drained on the thirty-third hospital day. Abundant colon bacilli were cultured from the fluid.

Postoperatively the patient had a low-grade fever and frequently required oxygen. On the eighth hospital day an x-ray film of the chest was considerably changed, showing multiple rounded indefinite areas of increased density throughout both lungs. The appearance of the right lower lobe was unchanged. Twenty days postoperatively, after the temperature had been normal for five days, the patient was discharged to a nursing home.

Second admission (two months later). After discharge the patient was bedridden and continued to have a cough, dyspnea and a chronic draining wound in the upper abdomen. Two days before readmission the cough increased and there was an exacerbation of fever, with chills and headache.

The patient was moribund on admission. The findings were altered from the previous ones only in degree of severity. Rales and rhonchi were heard over both lung fields. The process seen in the x-ray film of the chest had moderately increased. The foci of increased density were connected by a network of increased densities, which were somewhat beaded and irregularly distributed. Death occurred on the third hospital day.

DIFFERENTIAL DIAGNOSIS

DR. CARROLL C. MILLER. This case presents the aspects of a picture puzzle of three pieces, which have to be fitted in proper relation to one another to explain the final outcome. These three pieces are the appendix abscess, resulting from a ruptured appendix, the lung abscesses and the liver abscess. It seems to me that the important feature is the sequence of events, provided that we can demonstrate a logical sequence. In the first place, I believe that there was nothing in this case that could be considered specific, that is, I do not believe that we are dealing with a specific infection. The mention of a liver abscess makes one think of amebic abscess or echinococcal disease of the liver, both of which can cause complications such as those that occurred in this case. In a man of this age we particularly think of carcinoma or malignant disease, and malignant disease in the lung or liver is frequently masked by infection. There is nothing in this man's history, however, that suggests malignant disease, although, of course, it may have been present. It is true that there was a loss of 71 pounds in weight, but after all, this man had a history, going back over a year, of chronic sepsis, and patients with this degree of chronic sepsis often lose weight. I believe that the weight loss can be explained on that basis.

Let us first consider the appendix abscess. These days we see, fortunately, few cases of late complications of appendix abscess. Whether this is due to a better handling of acute appendicitis and rup-

tured appendix or to chemotherapy, one cannot definitely say, it probably depends on both to a certain degree. The story of appendix abscess followed in a short space of time by chills, sweating, high fever and pain in the right lower chest make me believe that there was a spreading infection from the region of the appendix or cecum. Pylephlebitis, with a spread of the infection through the veins of the portal system into the liver and the subsequent formation of multiple liver abscesses, would explain the clinical signs and symptoms.

So far as the lung abscesses are concerned, there are two possible explanations. One, which is attractive, is that since this operation was for an acute ruptured appendix it undoubtedly was an emergency procedure. We do not know the details of the operation, what anesthesia was used or what complications were associated with the immediate operative or postoperative situation, but it is possible that material was aspirated from the stomach — that is, vomitus during induction or recovery from the anesthesia may have been aspirated into the lung, with the resultant formation of multiple lung abscesses. A good many cases of lung abscess come to this hospital in which this has been the story. Usually these abscesses start out as tiny foci of infection surrounding the aspirated material, many of them in various parts of the lungs but mostly in the lower lobes. These abscesses, particularly if they are peripheral, cause pleuritic reaction with effusion and eventual contamination of the pleural cavity, with the formation of empyema. So the empyema that was found and drained may be explained on the basis of an abscess going out from the central part of the lung to the periphery. That is one direction for the train of events. Another direction, which is not infrequent, is that in a cephalad direction that is, the infection in the abdomen may have gone up under the diaphragm, perforated the diaphragm and caused an empyema, which in turn invaded the lung. This involvement of lung tissue from without is rarer, I should say, than involvement of the pleura from within the lung parenchyma. The liver abscess, as such, might have produced the same sequence of events, breaking through the diaphragm without peritoneal involvement and causing empyema and lung changes.

I should like to speculate a minute on the matter of chemotherapy, which has some bearing on this case. The patient was given sulfonamides and penicillin following the first bout of sepsis in the chest. So far as appendix abscess is concerned, we have had varying responses with the use of sulfonamides. Both sulfadiazine and penicillin have frequently seemed beneficial in cases of peritonitis from ruptured appendix. But these drugs are notorious, of course, for affecting the gram-positive organisms and not affecting the gram-negative ones, and that is borne out by the fact that in this case colon bacilli were cultured from two sources — the

about by the cellophane. The application of cellophane is not a new maneuver, but its use under similar circumstances is worth while for the possible continuing stimulation of fibrosis within the ductus

(To be concluded)

CASE 32151

PRESENTATION OF CASE

First admission. A sixty-five-year-old railroad conductor was referred from another hospital with a diagnosis of multiple abscesses of the lung.

Eight months before admission the patient had an appendectomy, with drainage because of rupture, at a community hospital. Two weeks later an abscess in the region of the cecum was drained. This was soon followed by an episode of chills and sweating, accompanied by a high fever and pain in the right lower chest. A small amount of pus was removed from the right pleural cavity. The patient received sulfonamides and penicillin and was discharged apparently well in the seventh week. Two weeks after discharge he again developed chills and fever and was readmitted. The empyema was treated by drainage and local penicillin, and he was discharged after a four-week stay. Six weeks later he entered another hospital, again with chills and fever. There was a draining sinus in the right lower posterior chest. Injection of the sinus with lipiodol showed a multilocular abscess at the level of the right hilus, with a fistulous communication into a large bronchus. He received parenteral penicillin with improvement and was discharged after six weeks, one month before his admission to this hospital. He continued to have fever and sweats

He raised large amounts of yellow, nonodorous sputum, and three days before admission the sputum became blood streaked for the first time. There had been marked dyspnea in the latter part of his illness. During the whole course he had lost 71 pounds.

On physical examination the fistula was draining small amounts of pus. There were dullness and diminished fremitus over the lower two thirds of the right chest anteriorly and posteriorly, the breath sounds were harsh and loud, and there were scattered fine rales over this area. The heart was slightly enlarged to the left, and there were numerous extrasystoles. The liver edge was 3 cm. below the costal margin. The appendectomy scar was healed.

The temperature was 101.5°F, the pulse 72, and the respirations 24. The blood pressure was 135 systolic, 65 diastolic.

The red-cell count was 3,590,000, with 10 gm hemoglobin. The white-cell count was 30,000. The urine was normal. An x-ray film of the chest showed considerable radio-opaque material in a large cavity in the apex of the right lower lobe. There was hazy increased density throughout the rest of the lobe. The right half of the diaphragm was high and immobile.

A bilateral superficial femoral-vein ligation was performed on the second hospital day. Several unsuccessful attempts were made to aspirate the right pleural cavity. On the fifteenth hospital day, the liver was tender and there was spasm of the overlying rectus muscle. The total protein was 7.19 gm, with an albumin-globulin ratio of 0.84. The prothrombin time was 26 seconds (normal, 18 seconds). By x-ray examination the liver did not appear enlarged, and its upper outline was sharply defined. A gastrointestinal series failed to reveal any deformity of the stomach or duodenal loop. Abundant colon bacilli were cultured from the sputum. In the meantime the patient had had two attacks of substernal pain, one accompanied by dyspnea, and the temperature was spiking. Several abdominal films taken during thorotrast study showed an area of decreased density within the

abscesses throughout the lungs. We did not find a thrombophlebitis. The vein ligation was described as being prophylactic in character. Infection can, of course, spread by metastases through the venous system without producing progressive thrombosis. Although the clinical sequence seems to point to lung abscess and then liver abscess, I am inclined to think that the reverse order is more probable, the first process being in the liver and the second in the lungs.

You have already heard the bacteriologic report that colon bacilli were cultured from the sputum. When the sections came through we found microscopically an additional organism, which helped to explain the failure of response to chemotherapy. The abscesses in the lungs contained numerous actinomycotic granules. We did not find any in the liver, but I presume that the process there was of the same etiology.

We did not find any lesion in the brain.

CASE 32152

PRESENTATION OF CASE

A twenty-one-year-old woman, a switchboard operator, entered the hospital complaining of severe headaches.

Four or five years before admission, she noticed the onset of diplopia. At first this condition was corrected by prismatic glasses, but it grew progressively worse, requiring frequent change of lenses, and one year before admission the diplopia persisted in spite of glasses. Approximately concomitant with the onset of the diplopia, the patient began to have "cramps" in the right hand. These were accompanied by a cold, numb feeling sometimes limited to the fingers and sometimes involving the entire hand. During these attacks the hand felt "frozen" in whatever position it had occupied at the onset, it did not tingle or feel numb. The right leg was never affected, and there was no disturbance of speech. One year before admission the patient began to have paroxysmal attacks of sharp stabbing pains distributed symmetrically over both cheek bones and sides of the nose but never involving the supraorbital regions, jaw, teeth or gums. These attacks occurred three to four times a day and lasted two to three minutes. They were accompanied by a cold, numb feeling having the same distribution as the pain but persisting constantly for about a week, during which the attacks of pain occurred. Then both pain and numbness subsided, to recur again for one-week periods once or twice a month. Six months before admission, the attacks of pain in the face subsided but there was an increase in the frequency and intensity of the mild headaches that she had been having occasionally ever since an illness, thought to have been undulant fever, at the age of seven.

They became severe, stabbing and throbbing in character, extending diffusely over the head but occasionally becoming more marked over the temporal and occipital regions bilaterally. They often awakened her in the early morning, gradually fading in severity after two or three hours. The onset was usually accompanied by nausea, which was sometimes followed in about half an hour by vomiting. Occasionally the patient experienced a momentary "blackout" when she stood up during one of the severe headaches, but she never lost consciousness for more than a few seconds. She also complained of severe blurring of vision during the headaches. These attacks occurred about once or twice a week without apparent precipitating factors and did not respond to any form of treatment. During the six months before admission they did not increase in frequency but gradually became severer, lasting up to six hours and then gradually fading throughout the day.

The past history and family history were non-contributory.

Examination revealed a well developed and well nourished girl in no acute distress. There was papilledema of 2 or 3 diopters in the right eye, and 1 diopter in the left. The pupils were equal, being 4 mm in diameter, and reacted normally to light and distance. There were convergent strabismus of the right eye and homonymous diplopia, persisting even on extreme lateral gaze to the left. There was no anosmia. The corneal reflexes and sensation of the face were normal. There was no facial asymmetry or weakness. An audiogram was normal. The palate and tongue were normal. There was no unsteadiness or weakness of the arms or legs. Sensation, including postural sense and stereognosis, was normal. The arm, knee and ankle jerks were brisk and bilaterally equal. There was no Hoffmann reflex. The plantar reflexes were normal.

The temperature was 99°F, the pulse 95, and the respirations 20. The blood pressure was 120 systolic, 75 diastolic.

The urine was normal. The red-cell count was 4,400,000, the white-cell count 8700, and the hemoglobin 80 per cent. The spinal fluid, which was under a pressure equivalent to 350 mm of water, was xanthochromic and contained 30 red cells and no white cells per cubic millimeter. The total protein was 7 mg per 100 cc, and the goldsol curve and Wassermann reaction were negative.

An electroencephalogram was abnormal, with slow activity increasingly prominent posteriorly. Although there was no well defined focus, the slow activity (4 to 5 seconds) was especially prominent in the left occipital and the right posterotemporal regions.

X-ray films of the skull showed unusual prominence of the convolutional markings. Only one posterior clinoid process, thought to be the right, was seen, and that seemed to have a blunted tip.

sputum and the liver abscess. Apparently the use of sulfonamides inhibited the other organisms, so that there was a persistence of colon-bacillus infection in spite of the repeated use of penicillin and sulfonamides.

It is surprising that these abscesses of the lung were apparently not foul. This is relatively unusual, but on the basis of chemotherapeutic responses, we can assume that some of the organisms that ordinarily cause foul abscesses were killed by the chemotherapy. Blood streaking of the sputum is a finding that we see frequently in lung abscess. It is not necessarily a sign of infarction or of malignant disease, but we have to think about infarction and pulmonary emboli in relation to the other findings.

A point of interest to me is the reason for the superficial-vein ligation. In this hospital we are naturally highly sensitized to the matter of embolic catastrophes coming from the veins of the legs. I should be interested to know whether this ligation was done as a prophylactic measure or with the conviction that the episodes of pulmonary difficulty were secondary to thrombophlebitis of the legs. It seems that the latter was probably the case. We are not told whether clots were found in the veins, and no mention is made of the flow of blood from above. It would be of some interest in this case, because I suspect that there was a phlebitis in the abdomen above the point of ligation. In the early days of his illness this man had repeated episodes of chills, fever and chest pain. After he came to the hospital he again had episodes of pain, two of them substernal, accompanied by dyspnea, which to me suggest pulmonary infarction. Before we see the x-ray films I shall briefly mention the second admission, which simply showed an exacerbation of all the signs previously manifested, with, in addition, headache. This may have been simply a reflection of the sepsis and of the high temperature, but it is suggestive to me of the possibility of a metastatic brain abscess. The headache was not mentioned previously, and we know that the three most frequent causes of death in lung abscess are sepsis, hemorrhage and brain abscess.

May we see the x-ray films?

DR JAMES R. LINGLEY: These are the first films and show the large area of density at the right base, which in the lateral view lies posteriorly and evidently represents encapsulated fluid. The appearance of the lipiodol suggests an alveolar distribution rather than lipiodol lying in a cavity. It was stated in the record that it communicated with the bronchus on the left side. In the lateral film there is a diffuse process, even at this time, of patchy areas of density distributed throughout the lung. This is the film taken five weeks later. There is a marked advance of the process throughout the left lung. The areas of involvement are small and circumscribed, yet it is a diffuse process involving the entire lung field.

DR MILLER: Do you think that is a cavity?

DR LINGLEY: I cannot see anything that looks like a cavity except this area on the right.

DR MILLER: It is possible that that might be an advance of the diffuse linear process seen in the previous film.

DR LINGLEY: Yes.

DR MILLER: Have you the thorotrast films? They are of some interest.

DR LINGLEY: This film after thorotrast injection shows two areas of diminished radiance and rarefaction in the liver.

DR MILLER: In recapitulation, I assume that this patient had a septic phlebitis arising in the region of the cecum and involving the iliac vein on that side and perhaps spreading up the inferior vena cava, although I find no sign of caval blockage in the picture that is described. I suppose that we must also predict a pyelephlebitis to account for the liver abscess, because I do not believe that a process coming down from the lungs could have produced these multiple liver abscesses. So, although the temptation is great to ascribe the multiple lung abscesses to aspiration from the esophagus at the time of operation or shortly thereafter, I am a little more in favor of the picture's being explained on the basis of septic infarction of the lungs, arising from the right iliac vein, with metastases to the lung, and eventually from the lung to the brain to explain the possible brain abscess. The pyelephlebitis may have followed an independent route, traveling through the portal system into the liver.

CLINICAL DIAGNOSIS

Multiple abscesses of lung and liver

DR MILLER'S DIAGNOSES

Thrombophlebitis, right iliac vein
Septic lung infarcts, with abscess formation
Pylephlebitis
Liver abscesses
Brain abscess?

ANATOMICAL DIAGNOSES

Multiple abscesses, pericecal, hepatic and pulmonary
Actinomycosis of lungs
Operative wounds: appendectomy, old, drainage of empyema and lung, subdiaphragmatic and liver abscesses
Arteriosclerosis, generalized

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: At autopsy, we found abscesses in three areas. There was a persisting abscess in the region of the cecum that had not been entirely drained. There was a large abscess in the liver, which at the time of autopsy appeared as a single abscess, although it may well have been multilocular in the early stages, and there were multiple

On the positive side of the balance there are yet other reasons for thinking that the ventriculogram is a correct portrayal of the situation. The headache was periodic, but its periodicity was not without system. We note that the patient was frequently awakened by headache, but that on assuming the erect posture it subsided, at first within an hour or two and somewhat later in the disease only after five or six hours of being out of bed. This suggests that the headaches were due to intermittent obstructions to the flow of cerebrospinal fluid that were related to changes in posture. A mass situated in the third ventricle is certainly in a strategic location for producing such a ball-valve action on the circulating fluid. Supporting this as a possibility is the finding that the spinal fluid was yellow and contained a little blood.

DR. KUBIK: The lumbar puncture was done after the ventriculogram.

DR. HEUSNER: My abstract says that the spinal fluid was xanthochromic.

DR. KUBIK: I am sorry about that.

DR. HEUSNER: We cannot, then, call on xanthochromia as a means of supporting the possibility that something was protruding into the ventricular system, but that is a finding we have come to recognize as likely when some abnormal tissue is lying in a subependymal position or actually within a ventricle.

But there are other reasons for accepting the ventriculographic suggestion of a mass in the posterior portion of the third ventricle. If we are to explain the symptomatology on the basis of a single lesion, that lesion must be in close proximity to the central sensory components subserving both sides of the body, for although it is true that the pains began in the right hand, later in the disease they appeared bilaterally over the face. Certainly a mass in the third ventricle, the walls of which are composed in part of the thalami, important sensory substations, would be favorably situated to effect bilateral pain. I do not know how a lesion in that position actually produces pain, yet the clinical description of this patient's discomfort is to me not unlike what we sometimes see following a thrombosis involving the thalamus. For these several reasons, then, I am going to accept the ventriculogram as having demonstrated the presence of a space-occupying something in the posterior portion of the third ventricle.

This is a long history. What slowly growing things occur in this region? Accumulated experience shows that practically everything from granulomas and parasitic cysts through various tumors have been found in this location. But since we have nothing to suggest a granuloma or parasitic cyst, I am going to confine my comments to the reasonable statistical possibilities, namely, the tumors

Of the tumors that come to occupy the third ventricle, the great majority arise outside the ventricle and eventually extend into it, the minority are primary intraventricular tumors. Of the tumors that arise outside and eventually gain access to this ventricle, the most frequent one is, I think, the Rathke-pouch tumor. In this case I do not believe that we need seriously consider such a lesion. The characteristic visual-field changes and suprasellar calcification are wanting, and what is more significant, the anterior portion of the third ventricle was visualized. Such a tumor should obstruct the anterior portion of this cavity before the posterior part is obliterated. On similar grounds I shall eliminate the occasional pituitary tumor that bursts its bounds, reaches the third ventricle and produces a hydrocephalus, the visual-field changes characteristic of that lesion are missing, the sella is not ballooned, and the anterior portion of the third ventricle was visualized. There is, however, a relatively frequent group of tumors arising in the pineal body near the back of the roof of the third ventricle. Such tumors not infrequently extend downward and come to fill a part or even all of this ventricle. I see no way of ruling out such a growth in this case, even though the patient did not show the large fixed pupils and impairment of upward gaze that are sometimes produced by such a mass pressing on the tectum of the midbrain.

There are two tumors that frequently arise within the third ventricle, if any third ventricular tumor may be said to be frequent—colloid cyst and papilloma of the choroid plexus. I see no way of definitely ruling out either of these. Yet, in the great majority of cases colloid cysts arise from the anterior portion of the roof of this ventricle,¹ and since that portion of this ventricle was visualized I should not expect this patient to harbor a colloid cyst. In other words, it seems as if this patient's mass originated more posteriorly than is usual for colloid cyst. Papilloma of the choroid plexus, on the other hand, is apt to arise from the posterior portion of the roof, and it is notorious that tumors arising in that region may go for a long time before they give rise to serious obstructive or neighborhood symptoms. So, it appears to me that the likeliest statistical possibilities in this case are pinealoma and papilloma of the choroid plexus.

The position of a mass occupying the third ventricle is of extreme importance to the surgeon, because if he can be certain of this his operative approach is likely to be successful. In a case of this type the surgeon is primarily interested in knowing whether the tumor is more accessible from the back or from the front of the ventricle. The air studies provide the answer: the tumor was more posterior than anterior.

My diagnoses are internal hydrocephalus, involving the lateral ventricles and the anterior portion of the third ventricle, and a tumor occupying the

A ventriculogram showed both lateral ventricles well filled and normal in shape and position, but they appeared to be somewhat enlarged. No air was seen in the third ventricle, aqueduct or fourth ventricle. The foramen of Munro was visualized.

An operation was performed.

DIFFERENTIAL DIAGNOSIS

DR A PRICE HEUSNER* Before undertaking an analysis of this case I should like to ask two questions. Are the results of a visual-field examination available? Is the abstract correct in reporting that the spinal-fluid total protein was 7 mg per 100 cc?

DR CHARLES S KUBIK That was ventricular fluid. The visual fields were normal except for large blind spots resulting from the papilledema.

DR HEUSNER But nothing striking.

DR KUBIK No.

DR HEUSNER We are asked to consider a twenty-one-year-old woman who was forced to enter the hospital because of increasing severity and frequency of headaches, which she had had for as many as twelve or fourteen years. It is quite difficult, I believe, to make sure whether these headaches were a part of the present illness or whether she had them from some other cause. In any event she had had headaches, and they finally forced her to the hospital, with nausea and vomiting. Five years before admission she noted the onset of what became a persistent diplopia, and at about the same time she began to suffer paroxysmal painful subjective sensations in the right hand. The latter apparently subsided after an unstated length of time, but some four years later they were followed by the development of similar paroxysmal sensations that occurred in a butterfly distribution over the face—in other words, they were bilateral.

The various examinations done at the time of admission give us unequivocal evidence of the existence of an elevated intracranial pressure: the disks were choked, the plain x-ray films showed convolutional atrophy, and the spinal tap revealed a pressure equivalent to 350 mm of water. On the other hand, this bizarre symptomatology, extending back at least five and perhaps as many as fourteen years, did not leave in its wake anything that I can regard as a definitely localizing neurologic sign. On admission she had an internal strabismus of the right eye, which I take to be evidence of palsy of the right abducens nerve and adequate cause for the diplopia that she had experienced for several years. The note that the diplopia persisted even in extreme left lateral gaze permits of more than one neurologic interpretation. It might mean a beginning palsy of the left abducens nerve or a disturbance of the mechanism, situated high in the mid-brain, that regulates conjugate movements of the eyes. Because no one of these signs may be depended on for localization when it occurs in con-

junction with an elevated intracranial pressure, it is not surprising that a ventriculogram was made. It would be helpful to see these films at this point and also the plain x-ray film of the skull, which was described as showing convolutional atrophy.

DR JAMES R LINGLEY These are the plain films showing the convolutional atrophy, as well as some thinning of the posterior clinoid process, but no definitely localizing signs.

DR HEUSNER The sella is not ballooned?

DR LINGLEY No, I should say that it is normal in size.

In the ventriculogram there is dilatation of both lateral ventricles, and you can trace air down into the anterior portion of the third ventricle. This small quantity of air in the anterior portion of the third ventricle outlines the anterior border of a mass that fills the posterior part of the ventricle. In the lateral view you can also see the mass projecting up into the floor of the lateral ventricles, more marked on the left side than on the right. The x-ray findings therefore indicate a mass filling the posterior portion of the third ventricle and projecting up into the floor of the left lateral ventricle.

DR HEUSNER There is therefore objective evidence that air failed to reach the body and the posterior portion of the third ventricle. This suggests the presence of a mass in the back end of the third ventricle, but before accepting this as an absolute certainty it would be wise to inquire whether the suggested localization is clinically reasonable. Although it is true that the ventriculogram remains the neurosurgeon's most reliable single localizing adjunct, it is not a method without caprice. Occasionally, even in the most experienced hands, failure to visualize some portion of the ventricular system does not mean that that portion of the system is occupied by a pathologic mass. Let us, then, harken back to the symptomatology and see if the localization suggested by this ventriculogram is clinically reasonable.

If we consider the over-all picture of a twenty-one-year-old woman with choked disks but without localizing signs, one of the first lesions we should think of is a neoplasm in the posterior fossa. We have, then, to ask ourselves whether it is more reasonable to expect a lesion in the posterior fossa or one in the posterior portion of the third ventricle, as suggested by the ventriculogram.

There are numerous reasons for accepting the ventriculographic localization in this case. The history and neurologic signs are not those of posterior-fossa disease. None of the cranial nerves in that region have suffered, and there are no signs or symptoms, such as ataxia, dysmetria and nystagmus, suggesting disorder of the cerebellum itself. Further, in posterior-fossa tumors the entire third ventricle shares in the hydrocephalic enlargement, a circumstance affording the best possible chance for filling that cavity with air.

THE INADEQUACIES OF MEDICAL CARE

I GENERAL CONSIDERATIONS

WHAT is wrong with the practice of medicine? As long ago as 1927 the Committee on the Costs of Medical Care was organized by a group of leading physicians, public-health authorities and economists to solve the problem — "the delivery of adequate scientific medical service to all the people, rich and poor, at a cost which can be reasonably met by them in their respective stations of life." Although extensive majority and minority reports were rendered at that time, matters have little improved, and the point has finally been reached at which compulsory health insurance is advocated by President Truman, certain congressmen and others as the *only* means by which the health of the Nation

can be assured. Such a scheme or any other plan for distributing the costs of medical care concerns merely one of the many factors that contribute to the health of the Nation. Similarly, the art and the science of medicine, which admittedly are developed in the United States to a degree that is unsurpassed in any other country, comprise another single factor. In other words, adequate and proper medical care for all largely depends on various socioeconomic factors with which the majority of physicians have had little experience and over which they have little control.

In any broad concept of matters pertaining to national health many factors have an equal, if not greater, influence than has medical care. These include good wages, a high standard of living, adequate housing and transportation facilities and a public well educated concerning proper diets, methods of preventive medicine and means of obtaining medical care. Although the lack of one or more of these factors renders the success of any system of medical care questionable, if not impossible, they have received little consideration by those clamoring for compulsory health insurance. Such matters, of course, are not true responsibilities of the medical profession, except for the fact that physicians might well play more of a role than they have in the past in matters of lay education. On the other hand, many inadequacies pertaining directly or indirectly to medical care exist, and the refusal to recognize and admit these faults has done much to lead to the position in which, unfortunately, the medical profession now finds itself.

In the last fifty years, the science of medicine has made tremendous progress, possibly at a sacrifice to the art. The "family doctor" as he existed in the nineteenth century is a person of the past, since it has become impossible for any one physician to care properly for *all* the aches and pains of his clientele. Although the man in general practice will undoubtedly continue to comprise the bulwark of the medical profession, being just as essential to it as was the infantry to the modern army, this advance in the science of medicine frequently demands elaborate diagnostic aids and the advice and technical skill of the so-called "specialist." In cases of serious illness, it has put a premium on hospitaliza-

posterior portion of the third ventricle — either a pinealoma or a papilloma of the choroid plexus

DR. AUGUSTUS ROSE How do you explain the diplopia?

DR. HEUSNER To explain that I have to fall back on the experience of others. The tumors that occur in this region are rare. I have seen very few of them, but the symptoms in 2 of Dandy's¹ 15 cases of primary intraventricular tumor began with diplopia.

DR. ROSE You think that it is a sixth-nerve palsy?

DR. HEUSNER I do not know.

DR. ROSE I do not know either.

DR. JAMES B. AYER Does not a pineal tumor usually show in a ventriculogram by the time that it has done this much damage?

DR. HEUSNER I believe so, and I also believe that Dr. Lingley pointed out a fullness extending up into the lateral ventricle in one of the projections.

I am glad that no one has asked me to explain the pain in this patient's arm or face, but again falling back on the experience of others, I find that similar pains have been observed, although not in

FIGURE 1

a butterfly distribution. Those who have tried to formulate clinical syndromes of third ventricular disease have included among them a so-called "thalamic syndrome" resulting from tumors in this region and characterized by spontaneous, often paroxysmal, pain.^{2,3}

In my abstract the spinal fluid was said to be yellow. Had the tap been done before the ventriculogram, I should have favored a papilloma of the choroid plexus ahead of pinealoma, but without that, I assume that the spinal fluid was initially clear. On statistical grounds I guess that a growth arising in the pineal is the likelier.

DR. WILLIAM H. SWEET The extreme duration of symptoms, as suggested by the convolutional atrophy of the skull, might also lead to the diagnostic possibility of an epidermoid tumor, since that is the slowest growing of the congenital-rest tumors that are seen in the third ventricle.

DR. KUBIK Would you like to add anything more about the operative findings?

DR. SWEET On the basis of the extreme duration of symptoms it appeared to me that a colloid cyst or an epidermoid tumor were the likeliest diagnoses. I searched a long time and finally found a small colloid cyst involving the third ventricle. I was not able to find any evidence that the lateral ventricle on either side had been encroached on by a space-taking mass and had a rather difficult task to get between the internal cerebral veins without hemorrhage. This was eventually achieved, and a small yellowish mass encountered, which was readily removable, it was not attached to any significant amount of the roof of the third ventricle, and after aspiration of the viscous fluid content, the collapsed capsule was readily lifted out.

DR. KUBIK How large would you say that it was?

DR. SWEET About 1.0 or 1.5 cm in diameter.

DR. KUBIK And the subsequent course?

DR. SWEET The patient was apathetic postoperatively for a week or two. After two or three weeks she began to behave normally, and when heard from three months postoperatively she had no complaints and was leading an active life.

CLINICAL DIAGNOSIS

Colloid cyst of third ventricle?

Epidermoid tumor of third ventricle?

DR. HEUSNER'S DIAGNOSES

Internal hydrocephalus, involving lateral ventricles and anterior portion of third ventricle.

Tumor occupying posterior portion of third ventricle (? pinealoma or papilloma of choroid plexus).

ANATOMICAL DIAGNOSIS

Colloid cyst of third ventricle.

PATHOLOGICAL DISCUSSION

DR. KUBIK The mass removed by Dr. Sweet, as he has already stated, was a colloid cyst of the third ventricle. A similar case has been reported.⁴ The patient was a forty-nine-year-old woman who had been having headaches for one year and became comatose a week before entering the hospital. There were no focal signs. The cyst, measuring about 1 cm in diameter, was attached to the roof of the third ventricle between the optic thalami. It is possible, I suppose, that its relation to the optic thalami accounted for pain or paresthesia, as suggested by Dr. Heusner. The section shows a thin cyst wall lined with columnar ciliated epithelium (Fig. 1). These cysts, which are benign and removable, are thought to originate from vestigial cells of the paraphysis.

THE INADEQUACIES OF MEDICAL CARE

I. GENERAL CONSIDERATIONS

WHAT IS wrong with the practice of medicine? As long ago as 1927 the Committee on the Costs of Medical Care was organized by a group of leading physicians, public-health authorities and economists to solve the problem — "the delivery of adequate scientific medical service to all the people, rich and poor, at a cost which can be reasonably met by them in their respective stations of life." Although extensive majority and minority reports were rendered at that time, matters have little improved, and the point has finally been reached at which compulsory health insurance is advocated by President Truman, certain congressmen and others as the *only* means by which the health of the Nation

can be assured. Such a scheme or any other plan for distributing the costs of medical care concerns merely one of the many factors that contribute to the health of the Nation. Similarly, the art and the science of medicine, which admittedly are developed in the United States to a degree that is unsurpassed in any other country, comprise another single factor. In other words, adequate and proper medical care for all largely depends on various socioeconomic factors with which the majority of physicians have had little experience and over which they have little control.

In any broad concept of matters pertaining to national health many factors have an equal, if not greater, influence than has medical care. These include good wages, a high standard of living, adequate housing and transportation facilities and a public well educated concerning proper diets, methods of preventive medicine and means of obtaining medical care. Although the lack of one or more of these factors renders the success of any system of medical care questionable, if not impossible, they have received little consideration by those clamoring for compulsory health insurance. Such matters, of course, are not true responsibilities of the medical profession, except for the fact that physicians might well play more of a role than they have in the past in matters of lay education. On the other hand, many inadequacies pertaining directly or indirectly to medical care exist, and the refusal to recognize and admit these faults has done much to lead to the position in which, unfortunately, the medical profession now finds itself.

In the last fifty years, the science of medicine has made tremendous progress, possibly at a sacrifice to the art. The "family doctor" as he existed in the nineteenth century is a person of the past, since it has become impossible for any one physician to care properly for *all* the aches and pains of his clientele. Although the man in general practice will undoubtedly continue to comprise the bulwark of the medical profession, being just as essential to it as was the infantry to the modern army, this advance in the science of medicine frequently demands elaborate diagnostic aids and the advice and technical skill of the so-called "specialist." In cases of serious illness, it has put a premium on hospitaliza-

tion and all that goes with it. Many persons, however, are unable to obtain admission to a hospital, either because the facility is nonexistent or because beds are unavailable, and combined with this lack or scarcity of hospital facilities is the apparent inability of the medical profession to adapt itself to the changing practice of medicine, either wishfully or because of ignorance of the basic factors that are involved.

The subsequent editorials of this series will point out what appear to be the present-day inadequacies of medical care—as they concern its distribution and cost, its quality and the various adjuncts that are closely associated with, if not essential to, its successful accomplishment—and to hazard a guess concerning what must be done if the health of the Nation is to be improved.

PENICILLIN AND SYPHILIS

A SECOND WARNING

IN A previous editorial in the *Journal*,¹ attention was called to the known fact that syphilis may lie dormant for long periods and later produce clinical effects or be transmitted to a second generation. Emphasis was laid on the importance of serologic follow-ups over a period of years in all persons who have been treated with penicillin for syphilis so that the exact potentialities and end-results of this method may be fully determined. In particular, returning veterans who had been treated for syphilis were mentioned as requiring this follow-up, because in many of them, early in the experimental period of this form of therapy, relatively small doses of penicillin were used. The same, however, may also be said of civilians—including those treated more recently with various combinations of penicillin with arsenicals and bismuths.

Of equal and perhaps greater importance is the need to search for serologic and clinical evidence of syphilis in patients who have been treated with penicillin for gonorrhea. The fact that gonorrhea and syphilis are frequently acquired at the same time but have different incubation periods, as well as the nature of the effect of small doses of penicillin

on the early manifestations of these two infections, renders the masking of the early manifestations of syphilis a definite possibility. Thus, the incubation period of gonorrhea is usually three to five days and only rarely more than a week, and its manifestations are usually obvious enough to the patient so that medical treatment is sought. As little as 100,000 units given in four or five intramuscular doses over a period of six to nine hours or a single dose of 200,000 or 300,000 units in a beeswax-peanut oil mixture produces complete cures in the great majority of cases. The incubation period of syphilis, on the other hand, is usually about three or four weeks and may be much longer. Treatment for gonorrhea may, therefore, be given some time before the primary syphilitic lesion appears.

Leifer and Martin² have recently reported on 15 cases of simultaneous infections from their own experience and from the literature. They very properly point out that for various reasons penicillin treatment of gonorrhea may be undertaken when primary syphilis is already present but overlooked or ignored. For example, a primary lesion may be missed because of its unusual location, it may be concealed by inflammatory phimosis, it may be regarded as an unimportant lesion or the diagnosis may seemingly be excluded by one or more negative dark-field examinations or by negative serologic tests for syphilis. In the earliest studies on the penicillin treatment of syphilis it was shown by Mahoney, Arnold and Harris³ that the primary lesion undergoes rapid changes within a few hours after treatment is started. With doses of 25,000 units every four hours, spirochetes disappear from the lesion, as shown by dark-field preparations, within sixteen hours or even earlier. There may also be clinical symptoms within the first eight hours that suggest a therapeutic effect. These include fever, pain at the site of the lesion and enlargement or tenderness of the regional lymph nodes, occasionally a brief rash resembling that of secondary syphilis appears.

Leifer and Martin also point out that the small doses of penicillin that are used in the treatment of gonorrhea may conceivably bring about a cure of a coincidental early syphilitic infection in rare cases. It is likelier, however, that a chancre will appear perhaps after a prolonged period of incubation. It

may be expected that treatment in the primary stages of syphilis will heal the lesion prematurely, after which it may either recur, the disease may be rendered asymptomatic or a secondary eruption may appear. In addition, a Herxheimer reaction may be evoked in the course of treatment, either at that time or on some subsequent occasion when penicillin is given. In the cases that they studied, the diagnosis of syphilis was proved in every instance either by demonstration of spirochetes in the lesions or by repeated positive serologic tests in less than ninety days after penicillin had been administered. On the basis of their observations these authors recommend that all patients treated with small doses of penicillin for gonorrhea² should have clinical and serologic observations for a period of three months.

Another interesting feature of penicillin treatment may be anticipated and has probably already been observed by some physicians. Many persons with latent or manifest syphilis undoubtedly receive penicillin therapy for other conditions, the drug being given for a brief course while the patient is acutely ill or in larger doses over longer periods for the treatment of such conditions as septic wounds, osteomyelitis and subacute bacterial endocarditis. In any event, an early febrile reaction may occur during the first few hours of penicillin treatment, and this may be accompanied by symptoms of various severity which may be easily overlooked or misinterpreted. A rise in fever, a chill or a headache may be considered as a phase of the infection that is being treated, and a rash may be considered as a sensitivity reaction to penicillin, whereas actually these signs and symptoms are manifestations of a Herxheimer reaction. Physicians should be on the alert for these types of reactions and should obtain blood for serologic tests for syphilis at such a time. Positive results may be reported in occasional cases in which previous tests have been negative or in which the diagnosis of syphilis has not otherwise been suspected.

OBITUARY

SAMUEL BAYARD WOODWARD

1853-1946

Samuel Bayard Woodward, the son of Samuel Woodward, a merchant of Worcester, Massachusetts, and his wife, Elizabeth Rogers Treadwell Woodward, was born August 24, 1853. On his father's side he was a descendant of Dr. Henry Woodward, who settled in Dorchester in 1653 and carried on the practice of medicine there. On his mother's side, the members of Thomas Treadwell's family were fellow passengers on the ship with Dr. Henry Woodward. They settled in Ipswich.

Another Woodward, Dr. Samuel, lived in Torrington, Connecticut, and Dr. Samuel Bayard Woodward I, grandfather of the subject of this obituary, settled in Weathersfield, Connecticut, later moving to Worcester, Massachusetts. He was the first superintendent of the Worcester Lunatic Hospital.

His grandson, after an adequate premedical preparation, including an A. B. degree from Harvard College, entered Harvard Medical School and graduated as one of the honor men of his class. He then was appointed house officer at the Boston City Hospital, where he won the confidence of the visiting staff and his associates. Having decided to prepare himself for the greatest possible usefulness in dealing with the problems of disease, he studied abroad for three years, visiting the hospitals of Dublin, London, Heidelberg, Vienna, Strasbourg and Paris.

On his return to his native city he immediately sought the advice of the older doctors and decided to settle in Worcester. He joined the Massachusetts Medical Society in 1877 and immediately became active in the affairs of the Worcester District Medical Society, being elected treasurer in 1886 and president in 1902. His election to the Council of the state society followed the next year. These positions, together with his activity on committees, were preludes to his election as president of the state society in 1916. Since his administration of the affairs of the Society was noteworthy, he was asked to accept the honor of a three-year term, a distinction not previously conferred since 1862.

His service during these years was especially arduous because of the threat leading up to and the declaration of war in 1917, which necessitated raising the required medical personnel for the Army and Navy, together with frequent meetings of legislative committees. Health insurance was being considered throughout the country at that time, and the Council appointed a committee to study the subject, but no reports were rendered and many years elapsed before this matter was brought up.

again and a successful plan adopted. Workmen's compensation also engaged the attention of the Society during the war years, and the law relating to this important economic matter was put into workable form after much study and many amendments.

By reason of Dr. Woodward's reputation for executive ability, he was requested by many financial institutions to help carry on the work of their corporations. In 1885 he united with others in the incorporation of one of the large savings banks of the state, later becoming its president. The success of this bank led to the development of a national bank and other savings banks in Worcester, with his name on the list of officers.

These activities led in turn to other important positions in a great variety of active corporations engaged in business, philanthropy, education and sociologic activities to the extent of thirty or more units to which he gave his time in meetings and important decisions, a most remarkable combination of responsibilities for a busy doctor to assume. His friends became concerned because of the likelihood of his inability to carry on so much without a breakdown, but his physical and mental energy seemed adequate for the demands made on his time and strength, and he continued this routine of attending innumerable meetings throughout the thirty or more years of his professional work and never relegated his medical interests to second place.

In addition to his hospital appointments, he especially enjoyed the position of trustee of the Worcester State Hospital, to which he gave much time, only to resign in 1914 under protest because of the change made to a paid board of three in place of the former unpaid board. He was able a few years later to have this serious mistake corrected.

His long contest before legislative committees to prevent the repeal of the law requiring the vaccination of school children covered many successive years. His voluminous papers, copies of addresses and many letters used in his arguments during this campaign were deposited in the Boston Medical Library several years ago.

These brief references to the work done and positions occupied by this public-spirited physician, who served his community, as well as his state, in many effective ways set a pattern of living that might well inspire others of equal strength and understanding to plan a routine of equal service to those who are in need of assistance and guidance, especially those who are victims of misfortune.

Two legacies in Dr. Woodward's will demonstrate his affirmation that medicine was his major interest. One is a large bequest to the Worcester District Medical Society for the creation or acquisition of a building in which meetings can be held and all the functions of the society can be efficiently carried on. The second is a grant to the Massachusetts Medical Society of an amount to augment the provisions of

the Cotting Fund, established by a former active and devoted member for the purpose of entertaining those members of the Council in attendance at its meetings, a wise and effective provision designed to promote harmony among the members.

Dr. Woodward has in a great variety of ways left with us a memory of his ideals and successes that should encourage emulation.

W P B

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

COUSENS — Nicholas W. Cousens, M.D., of Waltham, died March 19. He was in his eighty-second year.

Dr. Cousens received his degree from the Medical Faculty of Trinity University, Toronto, in 1891.

His widow and three children survive.

SULLIVAN — Cornelius A. Sullivan, M.D., of Braintree, died March 19. He was in his sixty-seventh year.

Dr. Sullivan received his degree from Tufts College Medical School in 1904. He was past president of Norfolk South District Medical Society, medical consultant, Norfolk County Hospital, staff member of South Shore Hospital, South Weymouth, and Braintree school physician for many years. He had been associate medical examiner for Norfolk County for twenty-two years. He was a fellow of the American Medical Association.

His widow, a son and four daughters survive.

NOTICES

ANNOUNCEMENTS

Dr. Julius Abramson announces his return from military service and the opening of his office for the practice of cardiology at 127 Bay State Road, Boston.

Drs. J. Englebert Dunphy and Stanley O. Hoerr announce the resumption of the practice of surgery at 721 Huntington Avenue, Boston, and 1101 Beacon Street, Brookline.

Dr. George H. R. Gosman announces that Dr. Joseph W. Tiede, having recently returned from active service, will be associated with him in practice at 121 Water Street, Boston.

Dr. Henry W. Hudson announces his return to the practice of surgery with offices at 1672 Beacon Street, Waban, and 1101 Beacon Street, Brookline.

Dr. Bernard M. Jacobson has returned from Naval duty and will resume the practice of internal medicine at 276 Commonwealth Avenue, Boston.

Dr. Elihu I. Lewis, having been released from active duty with the United States Navy, announces his return to the practice of internal medicine at 510 Commonwealth Avenue, Boston.

SUFFOLK DISTRICT MEDICAL SOCIETY

The spring dinner meeting of the Suffolk District Medical Society will be held at the Harvard Club of Boston on Saturday, April 27, at 7 p.m. Representative Edith Nourse Rogers will speak on the subject "Medical Legislation in Congress for Veterans" and Dr. J. C. Harding, assistant medical director for the auxiliary services of the Veterans Administration, will speak on "Highlights in Problems Relating to the Civilian Doctor and the Medical Care of Veterans."

Members and their wives are cordially invited to attend. The tickets which are \$3.00 each must be purchased in advance by sending cash or check to the treasurer, Dr. Richard S. Eustis, 319 Longwood Avenue, Boston 15, before April 20. After this date, other members of the Massachusetts Medical Society and their wives may apply.

CLINICAL AND LABORATORY STUDIES OF RELAPSING VIVAX MALARIA OF PACIFIC ORIGIN*

LIEUTENANT COLONEL HARRY H GORDON, M C, A U S, COLONEL ALEXANDER MARBLE, M C, A U S,
LIEUTENANT COLONEL STUART W LIPPINCOTT, M C, A U S,
MAJOR WILLIAM B HESSELBROCK, S N C, A U S, AND
CAPTAIN LESTER D ELLERBROOK, S N C, A U S

SINCE members of the armed forces have been stationed in areas in which malaria is prevalent, many of them will experience symptoms of the disease, either as delayed primary attacks or as relapses, when suppressive treatment is discontinued on their return to nonendemic areas. It seems worth while, therefore, to present a brief summary of the clinical features and laboratory findings in 808 soldiers admitted from Pacific areas to the Malaria Section of the Harmon General Hospital from August, 1943, to March, 1945. Certain of the data have been presented in greater detail in recent articles 1-4.

TYPE OF MALARIA

Although the patients came from areas in which falciparum malaria was endemic, and although many of them stated that some of their previous malarial attacks had been caused by *Plasmodium falciparum*, this organism was demonstrated in only 1 of 864 clinical attacks, and in this case it contributed to a mixed infection with *P. vivax*. This evidence strongly supports the statement that the use of quinacrine (Atabrine) in adequate doses completely cures falciparum malaria.⁵ From the discussion that follows, it will be noted that the clinical features of vivax malaria observed in these patients differed considerably from those described in falciparum infections by Most and Meleney,⁶ but it should be pointed out that extremely few of the patients had arrived in the United States directly from areas in which there was inadequate control of mosquitoes.

INFECTIOUSNESS

The infectiousness of patients with clinical attacks of malaria depends on the presence of gametocytes in the peripheral blood. Thin smears were examined for gametocytes in a total of 401 attacks. In 196 (49 per cent), they showed gametocytes.

*From the Army Service Forces Eighth Service Command, Harmon General Hospital, Longview, Texas.

In 255 attacks, treatment was not begun for approximately forty-eight hours after the onset of the relapse. In only 41 attacks (16 per cent) did blood smears taken daily or twice daily show the development of two or more gametocytes per 100 white cells, a level at which it is considered worth while to attempt to infect mosquitoes for transmission tests.[†] Since prompt initiation of treatment quickly eradicated parasites (Table 1), it is

TABLE 1 Effect of Quinacrine on Blood Smears and Fever

INTERVAL AFTER BEGINNING OF TREATMENT*	PERCENTAGE OF 321 PATIENTS WITH NEGATIVE SMEARS†	PERCENTAGE OF 434 PATIENTS WITH ORAL TEMPERATURES OF 99.2°F OR LESS

*Treatment of acutely ill patients was begun soon after admission to the ward but only if both a positive smear and an oral temperature of 100°F or higher were present.

†Only those patients are included who had a smear taken on each day.

obvious that there is extremely little danger of transmission of the disease if it is diagnosed promptly and if treatment is begun immediately after a positive smear is obtained. This does not in any way mitigate the need for adequate mosquito control. During a period of over one and a half years during which patients with malaria have been treated at this hospital, not a single patient has been admitted to the wards whose disease was considered to have been contracted here.

CLINICAL FEATURES

The two essential clinical features of the disease as observed in this study were the relative mildness of the acute attack and its stubborn tendency to relapse.

†The parasite counts in these patients were made by the staff of the Laboratory of the United States Public Health Service Imported Malaria Studies. The transmission tests referred to were carried out by this group to determine whether overseas strains of malaria were transmissible by means of infected, laboratory-bred American mosquitoes. The results of this study will be reported elsewhere.⁷

Characteristics of the Acute Attack

Less than 10 per cent of the patients showed any cerebral symptoms. The prompt subsidence of such symptoms with routine therapy led to the impression that these manifestations were such as would be found in any group of patients with high fever.

The infrequency of troublesome vomiting is evidenced by the fact that parenteral fluids had to be administered in less than 10 of the 864 attacks. Nausea and vomiting were present in about one fourth of the attacks, but with subsidence of the acute febrile phase under quinacrine therapy these symptoms gradually cleared.

There were prompt subsidence of fever and other symptoms and rapid disappearance of parasites from blood smears with the administration of quinacrine in customary doses of 0.2 gm every six hours for five doses, followed by 0.1 gm three times a day for six days until a total of 2.8 gm had been given. Table 1 shows that on the second day after the beginning of quinacrine therapy, 94 per cent of the patients had negative smears and 71 per cent had a maximum oral temperature of 99.2°F or less. Since a large majority of these patients had previously had several attacks of malaria, most of which had been treated with quinacrine, the prompt eradication of malarial parasites in these attacks indicated the continued effectiveness of the drug in the acute attack.

Interval Symptoms

Although the acute attacks of malaria were relatively mild and the symptoms promptly subsided with quinacrine therapy, many of the patients complained of easy fatigability, nervousness and dyspepsia between relapses. In the majority of cases these symptoms seemed to be strongly conditioned by factors such as exposure to combat and adverse living conditions in the Pacific areas or previous personality problems. Recurrent malaria added to the patients' difficulties but was not primarily responsible for them. The patients needed much reassurance that the ultimate prognosis for the complete cure of their malaria was good, since they had returned to areas in which the chance of reinfection was slight.

Data on Relapses

The marked tendency to relapse is indicated by the fact that of 287 patients with attacks treated with quinacrine at this hospital and followed either until a proved relapse occurred or at least sixty days had elapsed after treatment was completed, 193 (67 per cent) had relapses. As is evident in Table 2, neither the continued use of small doses of quinacrine for sixty days (compare Groups II and III with Group I) nor the use of pamaquin (Plasmo-chin) in the indicated dosage (compare Group II

with Group III) had any significant effect on the ultimate rate of relapse.

In Table 3 it is seen that of all the relapses that occurred up to six or seven months after completion of treatment with quinacrine, 60 per cent took place within sixty days and 90 per cent within four months. The higher percentage of relapses in

TABLE 2 Number of Relapses following Treatment with Quinacrine *

Percentage of relapses	74	60	64	67

*All patients received 0.2 gm of quinacrine every 6 hours for five doses, followed by 0.1 gm three times a day for 6 days, until a total of 2.8 gm. had been given. At the completion of this therapy, the patients in Group I received no further treatment; patients in Group II received no treatment for 1 day, followed by 0.01 gm of pamaquin three times daily for 3 days, followed by 0.1 gm of quinacrine daily except Sunday until 60 days had elapsed from the institution of treatment. The patients in Group III received the same prolonged treatment as did those in Group II except that pamaquin was omitted, starting immediately after completion of the initial treatment with quinacrine.

†All relapses noted were proved by the finding of a positive blood smear with the exception of 2 patients, they occurred within 180 days after completion of treatment (Table 3). The mean days of observation of the patients without relapses and the probable errors of the means were as follows: Group I, 143.2±7.4; Group II, 119.9±3.7; Group III, 126.0±4.6. The differences between the means were in all instances less than three times the probable errors of the differences.

‡Includes 4 patients who had relapses while receiving small doses of quinacrine (Table 4).

the first month after completion of suppressive treatment (compare Groups II and III with Group I) may be related to the fact that plasma quinacrine concentrations at the completion of treatment of

the patients in Group I averaged approximately 45 microgm per liter, as compared with 25 microgm in Groups II and III (Fig. 1).

Although the use of 0.1 gm of quinacrine daily for sixty days had no significant effect on the ultimate relapse rate, there were only 4 relapses among 163 patients while they were on such continued small doses (Table 4). This extremely low incidence supports the observation in overseas theaters that the supervised administration of this dosage is an effective means of suppressing clinical malaria.⁸

In the two groups of patients given continued small doses, plasma quinacrine concentrations were determined each day during the initial week of

fasting concentrations from the second through the eighth day were 42 to 51 microgm per liter, whereas the average postprandial values two to

FIGURE 1 Comparison of Plasma Quinacrine Concentrations at Different Times

The broken line represents the average fasting plasma level in 104 patients given 2.8 gm of quinacrine in one week, the solid line that of 226 patients given the same amount of quinacrine in one week, followed by 0.1 gm of the drug on six days of each week. The latter specimens were taken 4 hours after administration of 0.1 gm of quinacrine.

treatment. As shown by Table 5, there was no relation between the plasma concentrations and the rate of relapse.

LABORATORY FINDINGS

Plasma quinacrine concentrations. The plasma concentrations⁹ obtained with the oral administra-

four hours after breakfast — on the second through the seventh day quinacrine was given three times a day with meals — were somewhat higher, being

tion of 2.8 gm of quinacrine in one week were determined in 226 patients during attacks. The results (Fig 1) are comparable to those reported by Shannon and his co-workers¹⁰. The average

49 to 57 microgm per liter. With these concentrations the symptoms of the attack were usually abolished within seventy-two to ninety-six hours. No attempt was made to determine the minimum effective dose, which presumably varied with the density of the parasitemia and the patient's immunity. Following cessation of quinacrine therapy,

the plasma concentration slowly fell, so that by four weeks after the initial dose the average value was 8 microgm per liter. The latter level is below the effective suppressive treatment level of 20 to 25 microgm attained when 0.1 gm of quinacrine was administered six days a week.

Complement-fixation reaction In the past, attempts to obtain a specific complement-fixation reaction with serums from human beings infected by *P. vivax* have led to inconclusive results. Since there are no certain clinical criteria indicative of a complete cure in vivax malaria, a complement-fixation test that could detect latent malaria would obviously serve an extremely useful purpose. The results of such a test with the use of an antigen prepared by Coggeshall and Frisch¹¹ from the chicken parasite *P. gallinaceum* are shown in Table 6. There

TABLE 6 Results of Complement-Fixation Tests during 234 Malarial Attacks and during Intervals Between 100 Observed Attacks

DAY OF ATTACK	NO OF TESTS	NO OF POSITIVE TESTS	NO OF ANTI-COMPLEMENTARY TESTS	PERCENTAGE OF NEGATIVE TESTS
1st	234	123	11	43
2nd	234	130	8	41
3rd	234	109	18	46
4th	234	127	10	41
5th	234	121	13	43
Interval tests	891	287	30	64

was a maximum of 58 per cent positive tests on any one of five successive days during 234 recurrent attacks. During intervals between 100 proved attacks, 64 per cent of 891 tests made at five-day intervals were wholly negative. Although the complement-fixation test gave a group reaction for the serums of human beings infected by *P. vivax*, it did not detect latent malaria as proved by subsequent relapses in a sufficiently high percentage of cases to be of practical value.

Liver-function tests Liver function was investigated in patients with recurrent attacks of malaria (Table 7). During the attacks transient disturbances were noted, as indicated by the results with the icteric index, serum bilirubin concentration, urine urobilinogen, bromsulphalein-clearance and cephalin-flocculation tests. Following attacks, only 5 per cent or less of the patients showed evidence of impairment by the cephalin-flocculation (Wilson antigen), bromsulphalein and galactose-tolerance tests. With a more sensitive reagent (Difco antigen), 20 per cent of the cephalin-flocculation tests were abnormal, but since neither antigen is standardized, this divergence in sensitivity cannot be interpreted. With both antigens, however, the trend was toward normalcy after the acute attack had subsided. Neither multiple attacks of malaria nor treatment with quinacrine resulted in evidence of permanent hepatic dysfunction.

SUMMARY AND CONCLUSIONS

Clinical and laboratory findings are presented for 808 soldiers admitted to the Malaria Section

of the Harmon General Hospital from Pacific areas.

In 864 clinical attacks proved by positive smears, *Plasmodium falciparum* was demonstrated in only 1, and then as part of a mixed infection with *P. vivax*.

The administration of adequate doses of quinacrine caused prompt disappearance of parasites from the blood stream. Without lessening the

TABLE 7 Incidence of Abnormal Tests of Liver Function during and following Attacks of Malaria

TYPE OF TEST*	NO IN GROUP		PERCENTAGE OF ABNORMAL TESTS						
	DURING ATTACK	AFTER ATTACK	DURING ATTACK					AFTER ATTACK	
			Day of Illness						
			1	2	3	4	5		
Serum icteric index	108	260	16	12	2	1	1	3	
Serum bilirubin	108	260	20	15	4			4	
Urine urobilinogen	176	227	20	19	14	4	3	1	
Bromsulphalein retention	151	149		4			1	3	
Cephalin flocculation (Difco antigen)	42	204	71	86	88	81	86	20	
Cephalin flocculation (Wilson antigen)	42	204	10	29	21	17	29	5	
Galactose tolerance		207						3	
Serum protein		172						2	
Serum cholesterol		156						0	
Serum phosphatase		191						0	

*The following standards were used as an index of abnormality: icteric index, more than 8 units per 100 cc serum; bilirubin, more than 0.5 mg. per 100 cc; urine urobilinogen, positive in a dilution higher than 1:20; bromsulphalein retention of more than 4 per cent in a specimen of blood taken 45 minutes after injection of 5 mg. per kilogram; cephalin flocculation, positive flocculation; galactose tolerance, excretion of more than 3 gm. in 5 hours after ingestion of 40 gm. of galactose; serum protein, less than 6.0 gm. per 100 cc; serum cholesterol, more or less than 150-250 mg. per 100 cc; serum phosphatase, more than 5 Bodansky units per 100 cc.

need for good mosquito control, this indicates that early diagnosis and treatment of relapses will help to prevent the spread of the infection in this country.

Symptoms of the acute attack were rapidly controlled by the administration of quinacrine in doses that yielded a fasting plasma concentration of 40 to 50 microgm per liter.

Following such treatment, 67 per cent of 287 patients had proved relapses in a period of six or seven months. Approximately 50 per cent of these relapses occurred within sixty days after completion of treatment. There was no relation between the plasma quinacrine levels obtained and the rate of relapse.

The complement-fixation test with an antigen prepared from *P. gallinaceum* gave a positive reaction in approximately 50 per cent of tests performed on each of the first five days of 234 recurrences, but 64 per cent of 891 tests performed during the intervals between 100 proved attacks were wholly negative. In its present form the test does not detect latent malaria, as proved by subsequent relapses, in a sufficiently high percentage of cases to be of practical value.

Multiple tests of liver function during and following attacks showed no evidence of permanent hepatic dysfunction.

LONGEVITY WITH VENTRICULAR ANEURYSM

Report of a Case with a Survival Period of Fifteen Years

CAPTAIN SIDNEY L. PENNER, M.C., A.U.S., AND CAPTAIN MICHAEL PETERS, M.C., A.U.S.

THE duration of life after an acute coronary-artery occlusion has long been regarded as brief, and it is only in recent years that the more optimistic viewpoint pronounced in 1912 by Herrick¹ has been justified. In increasing numbers, cases have been reported of survivals for as long as seventeen, twenty-four and even forty years²⁻⁵

not so much because of the presence of the out-pouching of the ventricular wall per se, as because this phenomenon is indicative of extensive myocardial damage. Cases have been reported, however, in which the patients have survived for as long as eight to ten years^{9, 10}. We present a case in which the patient survived a severe attack of

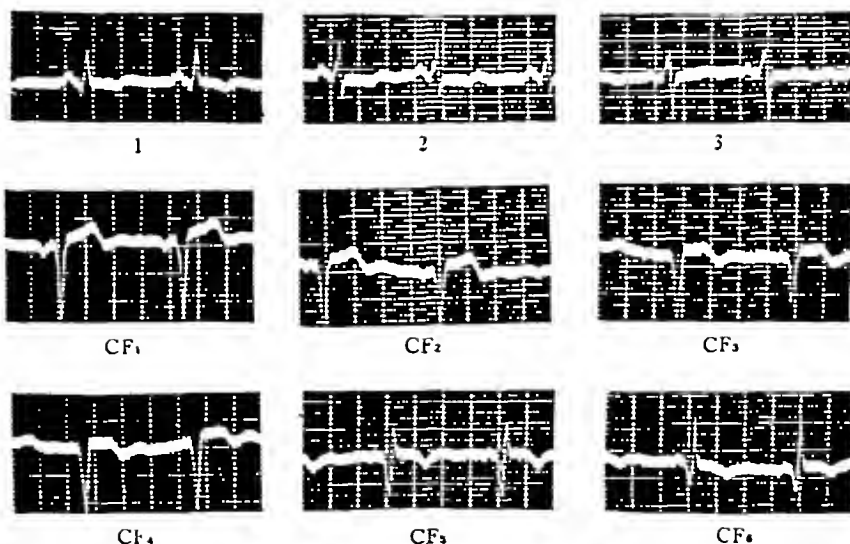

FIGURE 1

As an explanation of this change in prognosis, it has been suggested⁵ that the myocardial infarction that is being diagnosed in mild and atypical forms would have been dismissed years ago as so-called "acute indigestion" or never have been brought to the attention of a physician, and that these forms have a more favorable prognosis than do the severer ones.

The prognosis of cases of ventricular aneurysm has heretofore been considered as particularly grave,⁶⁻⁸ and the diagnosis has long been regarded as one to be made only at autopsy.⁷ This is true

myocardial infarction with subsequent ventricular aneurysm and was alive and in reasonably good health fifteen years after the acute episode.

CASE REPORT

A 43-year-old infantry officer on October 25, 1929, had an episode of severe pain in the precordium and left arm while crossing a parade ground. He was unable to walk farther because of the pain, which gradually subsided when he stood still. He had no further symptoms until November 18, when while reading he was seized with agonizing chest pain, radiating to the left arm. He was extremely weak and restless but was not dyspneic. The examining physician found the patient in a state of shock, with mild cyanosis, profuse sweating, a cold clammy skin and a barely perceptible pulse.

Severe pain persisted for several hours despite the administration of 75 mg of morphine. During the following several days the temperature was elevated, reaching a maximum of 102°F. A loud pericardial friction rub was heard, and rales were audible at the base of the left lung. The blood pressure was 120/76. On December 3, the patient was seen in consultation by Dr. George H. Anderson, of Spokane, Washington. Inverted T waves were noted in the electrocardiogram. No further details of this examination are available.

For the first 6 weeks after the onset of the illness, the patient remained in bed at home and his general condition

ST interval in Lead 1. On March 30, there was another attack of severe cardiac pain, followed by slight fever for 4 or 5 days. The patient gradually improved from this time on but remained in the hospital until February, 1931, when he was retired from the Army.

For the next 2 years he had slight pain in the right chest and left shoulder and arm but no other symptoms. After 1934 he felt well and was active in building and sailing boats and doing deep-sea fishing. In September, 1942, because of the war, he was returned to limited duty and was able to work in an administrative capacity without symptoms until

FIGURE 2

steadily improved. On January 31, 1930, he had a recurrence of pain, less severe than before but again followed by an audible pericardial friction rub. In February, he was transferred to a general hospital, where examination showed a traumatic cataract of the right eye and moderate thickening of the radial and brachial arteries. The blood pressure was 128/84. The heart was not enlarged, but the sounds were of poor quality and a soft systolic murmur was heard at the apex. There were no signs of congestive failure. The electrocardiogram showed a typical coronary T wave and

September, 1944. At that time he began to complain of pain in the left shoulder, radiating down the left arm and hand. There was occasional substernal distress, the pain being present at rest as well as on exertion. Cramps developed in the calves on walking and also on occasion during sleep. There was mild dyspnea on effort. An electrocardiogram was similar to those subsequently taken in April, 1945 (Fig. 1). Examination in that month showed thickening of the peripheral arteries. The blood pressure was 140/90. The heart was enlarged to the left on percussion, but there were no

thrills or abnormal pulsations over the precordium." The heart sounds were of good quality, and no murmurs were present. The first sound at the apex was split. No signs of congestive failure were present.

Electrocardiograms showed a regular sinus rhythm, left-axis deviation, slight slurring of the QRS complex in the limb leads, an inverted T wave in Leads I, CF₁, CF₂, CF₃ and CF₄, elevation of the ST segment in Lead I and depression

knob. The roentgenologic interpretation was left-ventricular aneurysm with calcification of the outer ventricular wall and apparent cardiac enlargement because of rotatory displacement of the heart, due to ventricular aneurysm.

The laboratory findings, including a complete blood-cell count, urinalysis, determination of the blood sugar and urea and Kahn and sedimentation-rate tests, were normal. The patient was kept in the hospital for several weeks for study,

FIGURE 3

of ST segments in Leads 2 and 3. The QRS complex in Leads CF₁, CF₂, CF₃ and CF₄ was completely inverted, and a large Q wave was present in Leads CF₁ and CF₂. X-ray examination of the heart showed the cardiac silhouette to be slightly enlarged (Fig 2). Overlying the left ventricular portion of the cardiac silhouette was seen a curvilinear, thin band of calcification forming the outer half of a soft-tissue condensation. Left lateral films showed encroachment of the left atrium on the esophagus. Fluoroscopic examination indicated that the calcification was in the outer surface of an outpouching of the anterior surface of the left ventricle. No pulsation was noted in this area. Bucky films taken in the right anterior oblique position (Fig 3) confirmed these findings and also showed calcification in the wall of the aortic

and on September 6, 1945, he was feeling well and again enjoying deep-sea fishing.

DISCUSSION

The diagnosis of cardiac aneurysm was not suggested by the physical findings,¹¹ nor did the electrocardiographic findings fall into the pattern said to characterize this lesion,¹² although it was characteristic of extensive anterior myocardial infarction. The x-ray examination, however, made the diagnosis clear. The following roentgenographic

criteria have been suggested⁸ for the diagnosis of ventricular aneurysm enlargement of the left ventricle with deformity of the cardiac contour, a localized protuberance of the silhouette, absent or abnormal pulsations under the fluoroscope, evidence of adhesions to the chest wall and calcification of the aneurysmal wall or intraventricular clot. Of these criteria, the present case showed the first, second, third and fifth. In addition, there was dorsal displacement of the esophagus^{14, 15}

Although the diagnosis of aneurysm was not established until 1945, it is justifiable to assume that the aneurysm was a direct result of the infarction or infarctions of 1929 and 1930. Ventricular aneurysm has been found to develop during the acute stage.¹⁶ The severity of the recurrent seizures, with pericarditis and fever as manifestations, and the persistence of symptoms requiring hospitalization for more than one year testify to the extent of the myomalacia. The present aneurysm had probably existed for the entire fifteen-year period and may have increased in size with the passage of time. The calcification must have been many years in development. The recurrence of symptoms in 1944 may have been due to one or more minor episodes of infarction, but the aneurysm was obviously of much earlier origin.

Since ventricular aneurysm has been found to develop even during the acute stages of myocardial infarction,¹⁶ and since the time for healing of an infarcted area has occasionally been found to be prolonged,¹⁷ the precaution of confining the patient to the hospital for over a year seems justified. During the next fourteen years, the patient reaped the benefit of his long convalescence, being able to lead an active and almost symptom-free existence. In this period of hospitalization, during which the demands on the myocardium were kept at a minimum, the formation of new anastomoses between the right and left coronary arteries and dilatation of the pre-existing anastomoses could take place.¹⁸ The enlargement of the defect in the ventricular wall under the impact of systole was diminished,¹⁹

and the danger of ventricular rupture was minimized.^{20, 21} Had a less conservative approach²²⁻²⁴ been employed, the result might have been disastrous.

SUMMARY

A case of ventricular aneurysm with a survival period of fifteen years is reported and is discussed in relation to the therapeutic implications.

OSSEOUS GAUCHER'S DISEASE WITH MACROCYTIC NORMOCHROMIC ANEMIA

Report of a Case

LIEUTENANT COLONEL ROBERT FIENBERG, M C, A U S, AND MAJOR GEORGE E. QUIGLEY, M C, A U S

IN THE typical cases of Gaucher's disease, the disturbance of the cellular metabolism, characterized by the accumulation and retention of the cerebroside kersin in the reticular and histiocytic cells, leads to the enlargement of the spleen and liver, with occasional osseous defects. In addition, there are pigmentation of the skin, pinguiculae, leukopenia, microcytic, hypochromic anemia and hemorrhagic tendencies due to thrombocytopenia. In the case reported below, the most prominent manifestations of the typical case of Gaucher's disease were absent. In fact, the presenting finding was an anemia that was discovered by the patient himself while he was practicing routine red-cell counts using his own blood. Subsequent examination disclosed the unusual combination of a macrocytic normochromic anemia with Gaucher's disease in which the spleen and liver were not palpable. The diagnosis was made possible only by the examination of the sternal bone marrow, since the radiologic appearance of the bones was normal.

CASE REPORT

A 20-year-old, Jewish laboratory technician was inducted into the Army in April, 1943. In the following summer, while undergoing basic training, he suffered pain in the right hip. This subsided in 4 days without treatment. Early in May,

unt of the skin. The abdomen was soft. Tenderness was present in the right upper quadrant. The spleen was not palpable, and the edge of the liver, which was tender, could be felt only on deep inspiration. During his hospital stay, the patient complained of "gas on the stomach" and appeared sluggish and weak. The possibility of an attack of infectious hepatitis was entertained on account of the symptoms, the yellow tint in the scleras and skin, the tender liver and the increased blood bilirubin. Pain was still felt in the right hip. The feces were always formed and brown. The patient was treated with a high-carbohydrate, high-vitamin diet and bed rest. On August 21, he was returned to duty. It was planned to perform a sternal puncture in a month to elucidate the nature of the anemia.

On September 28, a sternal puncture was done and a diagnosis of Gaucher's disease of the osseous type was made. On October 8, the patient was readmitted for further study. He had been feeling sluggish and weak and had had a poor appetite. Pain had continued in the right hip and lower back. No other member of the patient's family suffered from Gaucher's disease, although an aunt died of an anemia the exact nature of which was unknown to the patient.

On physical examination, the spleen and liver were not palpable. The malar flush and the generalized slight yellow tint of the skin were still present. The yellowish tint in the scleras was discovered to be caused by definite bilateral pinguiculae extending from the medial limbi of the cornea to the internal canthi. Roentgenograms of the entire skeleton revealed no lesions in the bones. On October 11, biopsies of the sternum and the left tibia were done. The sternal marrow did not look remarkable, but the tibia appeared devoid of marrow and a large amount of fluid blood came from the marrow cavity.

Pertinent data concerning the red cells and the hematologic indices and corpuscular constants are given in Table 1. On May 27, the white-cell count was 4850, with 45 per cent seg-

TABLE 1 Summary of Pertinent Laboratory Data

*The figure of 43.2 per cent was taken as the normal mean volume of packed red cells, and 14.5 gm per 100 cc. as the normal hemoglobin.

1944, while the patient was playing baseball, another attack of pain developed in the right hip and lower part of the back, although there had been no trauma or extreme physical exertion. The patient was then practicing red-cell counts, using his own blood, and discovered that he had an anemia. Following this finding, a diagnosis of macrocytic anemia was made. Free hydrochloric acid was found in the stomach. In the meantime, the pain in the back, which had persisted, suggested the presence of a ruptured intervertebral disk, but examination of the cerebrospinal fluid on June 2 disclosed nothing of significance, and a neurologic examination was negative. The patient was given 15 mg of thiamine daily, and the hip and back pain subsided. On August 1, the patient reported to sick call complaining of epigastric distress, nausea and anorexia. Physical examination revealed a well developed and well nourished man not acutely ill. There was a slight yellowish tint in the scleras, as well as a malar flush and a generalized slight yellowish

mented neutrophils, 6 per cent band neutrophils, 43 per cent lymphocytes, 4 per cent monocytes and 2 per cent eosinophils. Slight anisocytosis and slight poikilocytosis were present. On August 17, the white-cell count was 7000, with 40 per cent segmented neutrophils, 4 per cent band neutrophils, 46 per cent lymphocytes, 7 per cent monocytes and 3 per cent eosinophils. On September 5, the white-cell count was 6900, with 46 per cent segmented neutrophils, 2 per cent band neutrophils, 38 per cent lymphocytes, 3 per cent monocytes and 1 per cent eosinophils. Slight anisocytosis and slight poikilocytosis were present. On September 25 it was 8600, with 42 per cent segmented neutrophils, 15 per cent band neutrophils, 35 per cent lymphocytes, 3 per cent monocytes, 1 per cent eosinophils and 4 per cent basophils. Slight poikilocytosis was noted. On October 8, it was 5500, with 42 per cent segmented neutrophils, 12 per cent band neutrophils, 41 per cent lymphocytes, 3 per cent monocytes and 1 per cent eosinophils. Polychromatophilia, achromasia,

anisocytosis and poikilocytosis were present. No spherocytes were ever found. The platelet count was 250,000.

A red-cell fragility test on August 5 revealed that hemolysis began at 0.46 per cent saline solution for the patient and 0.46 per cent for the control and was complete at 0.36 per cent for the patient and 0.38 per cent for the control. Another test on October 8 showed that hemolysis began at 0.44 per cent for the patient and 0.46 per cent for the control and was complete at 0.36 per cent for the patient and 0.38 per cent for the control. The sedimentation rate (Westergren) was 11 mm per hour on August 6 and 24 mm on August 19, 1944. Two urinalyses were negative. Three Wallace-Diamond tests for urine urobilinogen disclosed no increase over the normal.

On May 26, 1944, a gastric analysis revealed 12 to 94 units of free hydrochloric acid and 28 to 106 units of total acidity. On May 28, no excess fat was found in the feces. On August 8, the blood nonprotein nitrogen was 33.9 mg per 100 cc and the blood cholesterol 200 mg.

The icteric indices and the corresponding quantitative bilirubin determinations (Van den Bergh reactions) are listed in Table 2. The Van den Bergh reaction was always indirect.

On August 7, the total serum protein was 8.2 gm per 100 cc and the albumin-globulin ratio 2:1. On August 8, the total serum protein was 7.2 gm and the albumin-globulin ratio again 2:1. In the Quick hippuric acid liver-function

blasts predominating. An occasional mitotic figure was found among the marrow cells. With the Giemsa stain, the Gaucher cells were pale, the cytoplasm being devoid of color. Otherwise the picture was similar to that found in the sections stained with hematoxylin and eosin. The Gaucher cells in sections stained with Mallory's aniline blue-orange G method were extremely prominent because their cytoplasm was stained blue. The cytoplasmic striations appeared to be accentuated, giving the cytoplasm a wrinkled appearance, and occasionally large vacuoles appeared in it.

The sternal marrow obtained by biopsy on October 11 was treated in the same way as was the sternal-puncture material. A direct smear stained with Wright's stain contained 8 per cent segmented neutrophils, 22 per cent band neutrophils, 8 per cent juvenile neutrophils, 13 per cent neutrophilic myelocytes, 4 per cent myeloblasts, 4 per cent pronormoblasts, 14 per cent normoblasts, 13 per cent lympho-

TABLE 2 Icteric Indices and Blood Bilirubin Levels

DATE	ICTERIC INDEX	BLOOD BILIRUBIN mg/100 cc
5/9	15.5	—
6/11	10.0	—
8/1	10.0	2.60
8/4	10.0	2.30
8/12	9.0	2.60

8/28	7.0	0.25
9/5	12.0	2.30
9/25	11.0	1.50

test (oral), the total excretion of hippuric acid amounted to 5.5 gm. On June 2, there were no white cells in the spinal fluid and the total protein was 32.3 mg per 100 cc.

The sternal-puncture material obtained on September 28 was smeared, and the small amount of blood clot remaining, which amounted to 0.4 cc., was placed in Zenker's fluid for sectioning. Staining of the direct smear with Wright's stain revealed 5 per cent segmented neutrophils, 32 per cent band neutrophils, 14 per cent juvenile neutrophils, 12 per cent neutrophilic myelocytes, 2 per cent myeloblasts, 2 per cent pronormoblasts, 11 per cent normoblasts, 18 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils and 1 per cent mitotic figures. In a general survey of the bone-marrow smears, scattered large cells were found, especially at the edges. These cells possessed abundant cytoplasm staining a light blue. Within the cytoplasm there were scattered striations, giving it a reticulated appearance. Infrequently a small vacuole was seen, and more rarely a purplish dot was found near the nucleus. The nuclei varied in shape, some being round and others slightly indented. In addition, multilobated and multinucleated types were noted. The chromatin pattern formed a coarse, open meshwork. The small blood clot fixed in Zenker's fluid was handled by the usual method for tissues. Examination of paraffin sections stained with hematoxylin and eosin revealed the presence of small fragments of marrow within the blood clot. Much of the marrow had been extensively replaced by compact masses of Gaucher cells. These large cells possessed abundant delicately striated cytoplasm. Many of the striations were arranged in concentric lines about the nucleus. Frequently the cytoplasm was diffusely yellowish brown. Ingestion of red cells by occasional Gaucher cells was noted, especially by those the cytoplasm of which was pigmented. Infrequently, acicular spaces were noted in the cytoplasm. Many of the nuclei were multiple or multilobated, whereas others were round or indented. Most of the nuclei were vesicular, with occasional large nucleoli. No mitotic figures were seen among these large cells. Among the marrow cells still remaining there was active hematopoiesis, with normo-

FIGURE 1 Group of Gaucher Cells Infiltrating the Sternal Marrow (x 225)

cytes, 10 per cent Gaucher cells, 3 per cent monocytes and 1 per cent mitotic figures. Megakaryocytes and platelets were few. The appearance of the cells was similar to that in the direct smear of the sternal puncture. The marrow in the tissue fixed in Zenker's fluid was similar to that found in the blood clot obtained by the first sternal puncture, except that the material was more abundant. In addition, the fatty tissue in the marrow was scanty and some of the Gaucher cells assumed a spindle appearance. The bone trabeculae were not remarkable. The Gömöri stain for hemosiderin stained the yellowish-brown pigment in the cytoplasm of the large cells blue, and the pigment was thus identified as hemosiderin. Sudan IV, the Schultz stain for cholesterol and the Smith-Dietrich stain were applied to direct smears of the sternal marrow, but none disclosed the presence of lipoids. The biopsy of the tibial marrow yielded little material. The direct smear consisted mainly of red cells, with a rare Gaucher cell. In paraffin sections, a small fragment of marrow was found in a blood clot that possessed the characteristics of the sternal marrow. A diagnosis of Gaucher's disease was made after microscopic examination of both the sternal and tibial marrows. Biopsy examination of the skin of the right flank on October 23 revealed no pigmentation or other abnormal details.

DISCUSSION

Several characteristics of this case deserve comment. Outstanding is the macrocytic, normo-

chromic anemia, a normochromic anemia being defined as one with a mean corpuscular hemoglobin concentration of 30 per cent or more. The lack of a palpable spleen and liver and of roentgenologic changes in the skeleton and the presence of bone pain and latent jaundice also merit attention.

According to Thannhauser,¹ the anemia in Gaucher's disease is usually microcytic, although he admits that the anemia may become macrocytic in the terminal stages of the disease. Pick² and Capper, Epstein and Schless³ state that the anemia is usually hypochromic, whereas Wintrobe⁴ describes it as normocytic and Mandlebaum and Downey⁵ call it chlorotic. Bloem, Groen and Postma⁶ reported 4 cases. In 1 the mean corpuscular volume was 108 cubic microns with a color index of 1.2, but the other 3 showed a hypochromic anemia. In the case reported by Melamed and Chester,⁷ there was a marked hypochromic microcytic anemia, but one examination out of twenty-one showed a macrocytosis. Finally, there was a hypochromic anemia in Petit and Schleicher's⁸ case. It is thus evident that the finding of a macrocytic normochromic anemia is unusual, but in the light of Davidson and Fullerton's⁹ report on the rare types of macrocytic anemia it is not unexpected, since infiltration of the marrow by the neoplastic cells found in some of their cases closely resembles the mechanism present in osseous Gaucher's disease, although the Gaucher cells are not per se neoplastic.

Most other writers are agreed that enlargement of the liver is usually an accompaniment of an enlarged spleen. As for the spleen, Thannhauser¹ states that it is always enlarged, and Krumbhaar¹⁰ emphasizes the importance of the size of the spleen in making a diagnosis of Gaucher's disease. Pick,² on the other hand, after studying cases of bone involvement by Gaucher cells in which the weight of the spleen and liver was less than the average weight of these organs in Gaucher's disease, directed attention to an osseous form that he considers to belong to a subgroup having a special constitutional predisposition for the skeletal system, so that occasionally all members in a family afflicted with the disease have a predominant involvement of the bones. Thannhauser¹ prefers not to set up a separate category but holds that the involvement of the skeleton is as constant as is involvement of the spleen. The latter is likely, but why the spleen should remain small in cases of Gaucher's disease in which the skeleton is involved, as in our case, is puzzling, nor is the solution of the puzzle advanced by the disclosure of the presence of Gaucher cells postmortem in a spleen weighing 100 gm in the case of Petit and Schleicher,⁸ in which there was also marked bone involvement. In the present case, the explanation may lie in the early stage of the disease, but this seems less probable in the case of Petit and Schleicher,⁸ in which the patient was seventy-nine years old.

It must be emphasized that the bones may be infiltrated by Gaucher cells without visible changes in the roentgenograms. This phenomenon is evident in our case and in that of Petit and Schleicher,⁸ and in both, diagnosis was made possible only by the examination of the sternal marrow. The diagnosis of Gaucher's disease in a man of fifty-two reported by Vogel, Erf and Rosenthal,¹¹ in whom no enlargement of the spleen or liver could be found, was also made by sternal puncture. In this case rarefaction of the bones could be seen in the roentgenogram.

In many cases of osseous Gaucher's disease, the presence of bone pain has led to erroneous diagnoses. Thannhauser¹ points out that bone pain, accompanied by fever, may be an early symptom and may simulate rheumatic pain. On the other hand, acute osteomyelitis may be mistakenly diagnosed, as happened in the case of Capper, Epstein and Schless.³ Welt, Rosenthal and Oppenheimer¹² also emphasize the presence of bone pain in this disease. In the present case, the diagnosis of a ruptured intervertebral disk was considered on account of the low-back pain, but a negative neurologic examination and normal findings in the cerebrospinal fluid aided in discarding this possibility.

The occurrence of jaundice is considered by Krumbhaar¹⁰ to be rare, whereas Thannhauser¹ states that a slight transient jaundice is an exception. According to Mandlebaum and Downey,⁵ it is absent. The last authors refer to jaundice that is clinically perceptible. A perusal of the reports in the literature, however, discloses the presence of latent jaundice in some cases of Gaucher's disease, including the osseous types. In fact, it was present in one of Thannhauser's¹ cases, and the statement that there may be a positive indirect van den Bergh reaction in cases of Gaucher's disease may be found in his review. In addition, latent jaundice was found in the case of Petit and Schleicher.⁸

The explanation of the mechanism of the production of latent jaundice in the osseous cases without enlargement of the liver has not been found in the literature and is open to speculation, especially since in the autopsied case of Petit and Schleicher⁸ no Gaucher cells were found in the liver, which appeared little altered from the normal. In the latter case, a hemolytic process may have been active, although no evidence was presented to support this. A definite hemolytic process was present, however, in a case of Gaucher's disease reported by Mandlebaum, Berger and Lederer,¹³ in which a diagnosis of hemolytic anemia was made. The possibility exists that a hemolytic process was active in our case also, but unfortunately no elevated urinary urobilinogen excretion was revealed by the Wallace-Diamond test, nor could reticulocytosis be detected. On the other hand, the presence of abundant hemosiderin in the Gaucher cells and the active erythrophagia by the same cells in the marrow in the present case

suggest that destruction of red cells was proceeding, but at such a slow rate that reticulocytosis and increased urinary urobilinogen did not appear. It was impossible to determine the amount of fecal urobilinogen excreted.

The deposition of hemosiderin in Gaucher's disease has been emphasized by Pick,² who believes that there is a storage of hemoglobinogenic pigments in lipid-storing cells. In fact, he states that hemosiderosis — or rather, increased blood destruction — occurs when the reticuloendothelial system is stimulated. This theory is probably too general, since hemosiderosis does not occur in Niemann-Pick's disease,² although here other factors, such as the age of the patient and the rapidity of the course of the disease, may contribute to the absence of the hemosiderin. It is well established that hemosiderin is either absent or extremely scarce in children with Gaucher's disease.² It is thus possible that erythrophagia and hemosiderosis vary in intensity in cases of Gaucher's disease and that it is in those in which the hemolytic process is at least moderately active that latent jaundice or even frank jaundice occurs.

That the episode of epigastric distress, nausea and anorexia in the case reported herein was due to an attack of infectious hepatitis is doubtful. Certainly at that time there was no rise in the blood bilirubin over that usually found in this patient, and there was no increase in the size of the liver.

It is true that the presence of the Gaucher cells in the marrow, with their characteristic wrinkled cytoplasm staining blue with Mallory's aniline blue-orange G stain and containing hemosiderin but no stainable lipid, made possible an unequivocal diagnosis, but before an examination of the marrow could be carried out other diseases in which a macrocytic normochromic anemia and an elevated blood bilirubin occur had to be ruled out.

Some of the diagnostic possibilities were pernicious anemia, nutritional macrocytic anemia, achrestic anemia, cirrhosis, congenital and acquired hemolytic jaundice and familial nonhemolytic jaundice. Sickle-cell anemia may be macrocytic and is accompanied by a hyperbilirubinemia, but this was not seriously considered on account of the race of the patient. Most of these possibilities were discarded through the data obtained from the clinical history, the physical examination and the laboratory studies other than that of the sternal marrow. Of all the suggested conditions, achrestic anemia and

familial nonhemolytic jaundice remained after the above studies were carried out. These were quickly discarded after an examination of the sternal marrow. Certainly, the demonstration of Gaucher's cells in the sternal marrow in this case offers another example of the value of sternal biopsy or puncture in the elucidation of blood dyscrasias.

SUMMARY

The diagnosis of a reported case of Gaucher's disease was made difficult by the presence of a macrocytic normochromic anemia with latent jaundice and by the lack of an enlarged spleen and liver, together with the lack of roentgenologic changes in the bones.

The sternal puncture alone made possible the diagnosis by the demonstration of Gaucher cells in the marrow. Once again, the value of sternal puncture in differentiating the blood dyscrasias has been proved.

It is suggested that the probable mechanism responsible for the production of the latent jaundice rested on the active erythrophagia of the Gaucher cells.

We are indebted to Dr. L. C. D. Hermitte, pathologist of the Sheffield Royal Infirmary, for the suggestions concerning the pathogenesis of the latent jaundice and for the photomicrograph.

MEDICAL PROGRESS

SURGERY OF THE HEART AND STRUCTURES RELATED TO IT (Concluded)

JOHN W. STRIEDER, M.D.*

BOSTON

TRAUMA

Wounds

What can be accomplished in the reduction of the mortality from wounds of the heart is ably demonstrated in a paper by Elkin¹² from the Department of Surgery at Emory University. Abstracts of the histories of 23 patients operated on for wounds of the heart are presented. In this series, the mortality rate was 22 per cent, as compared with 42 per cent in 38 cases previously reported from the same department. Although it has generally been considered that the intravenous administration of fluids prior to operation in cases of acute pericardial tamponade is contraindicated because of the danger of increasing the hemorrhage and hence the degree of tamponade, Elkin believes that such infusions have a beneficial effect by increasing the blood volume and hence the cardiac output. This point of view is based on the experimental work of Cooper et al.,¹⁴ who produced pericardial tamponade in dogs and then gave saline solution intravenously, with striking improvement.

Immediate operation was undertaken in all Elkin's cases, being performed as soon as the diagnosis had been made. As evidenced by the reported cases from other clinics, however, aspiration of the pericardium, either as a temporary or a definitive measure for the treatment of cardiac tamponade, may be properly employed.

Foreign Bodies

During the course of a war characterized by a high caliber of the medical services, many noteworthy papers dealing with the surgery of trauma of the thorax have naturally appeared. The experiences of Harken and his associates,¹⁵⁻¹⁷ in connection with foreign bodies in and close to the thoracic blood vessels and heart are particularly worthy of review, since they deal with practical aspects of intracardiac surgery, hitherto largely of theoretical conception as regards human beings.

These workers have removed missiles from within or adjacent to the great vessels of the thorax in 79 cases, in 3 of which the missiles were embolic. The latter were removed by Harken.¹⁸ His search of the literature revealed nearly 40 cases of embolic foreign bodies, but there were no examples of successful removal of embolic missiles from the great intra-

thoracic blood vessels. Harken assumes, however, that when all the reports of thoracic surgery performed in World War II have been published, these will include additional cases of successful removal of embolic missiles from these vessels. In the first of Harken's cases with removal, adequate roentgenograms were taken before embolization, and the embolus apparently moved from the liver to the left pulmonary artery. In the second case, movement was apparently through the heart and the embolus lodged in the innominate artery. In the third case, the embolus moved at operation from the left to the right pulmonary artery and was successfully removed from the right side at a second operation.

Harken and his associates state that certain foreign bodies impinging on the great vessels of the chest are removed to prevent erosion and hemorrhage or infection. In 15 per cent of the cases in this series the missiles were in abscesses, in 30 per cent, they were associated with other foreign material, such as bone or clothing, and in 67 per cent, they grew pathogenic organisms on culture.

In 59 cases, foreign bodies were removed from within or in immediate relation to the heart. In 13 of these, they were taken from the chambers of the heart. The indications for the removal of foreign bodies in the heart were originally set up on the basis of the medical literature, Harken's experimental work on dogs before the war and certain theoretical grounds. They are as follows: to prevent embolus (a foreign body or thrombus), to reduce the danger of bacterial endocarditis, to prevent recurrent pericardial effusions, and to diminish the incidence of cardiac rupture or myocardial hernia. It was believed that all four of these indications were supported by their own clinical experience and that of their colleagues. In addition, pain and cardiac neurosis may constitute indications for intervention.

Harken emphasizes that he and his associates elected to leave behind more foreign bodies than they elected to remove. Size and clinical manifestations were inevitable factors influencing their decision to operate. Small foreign bodies were thought possibly to be associated with less damage and to be less likely to cause the above complications than larger ones. They were, moreover, technically more difficult to remove. Inasmuch as it cannot be definitely ascertained from the literature just how hazardous retained intracardiac

*Visiting surgeon in charge of thoracic surgery, Massachusetts Memorial Hospitals and Boston City Hospital; assistant professor of thoracic surgery, Boston University School of Medicine.

foreign bodies are, and because some patients have undoubtedly remained asymptomatic for many years, the authors are reluctant to be dogmatic. They believe, however, that figures in the literature are misleading, because in many cases only roentgenograms were used in localizing the foreign body that was called intracardiac. They doubt whether some of these missiles were intracardiac, since in their own experience, in less than half the cases referred to them as having intracardiac foreign bodies, these were found on careful fluoroscopic examination to be in the heart. Furthermore, almost a third of the missiles that had been regarded as intracardiac were found at operation to be extracardiac. As these authors' experience widened, they felt justified in broadening their indications, since they had no deaths and since certain complications, some of them lethal, were observed to occur when the foreign bodies were left alone.

In the surgical procedure followed by Harken et al, the approach to the heart varies with the individual case and is planned so that minimal dislocation of the heart is necessary. The sternum, cartilage and ribs may be divided, but nothing is removed and no tissue is discarded. When adequate exposure is obtained, two rows of U sutures are placed on either side of the proposed cardiomy incision. These sutures are used as hemostatic sutures between manipulations and after the foreign body has been extracted with forceps. The myocardium is closed by approximating the margins of the incision with the inner row of hemostatic sutures and using the outer row to hold a pericardial graft in place.

In a dramatic case, three successive cardiomyotomies were performed at suitable intervals before the foreign body, which migrated twice, was successfully removed. It was originally in the right ventricle but moved to the right auricle at the first operation. When approached from the right side at the second operation, it moved from the right auricle back to the right ventricle. Because the patient was placed in the reverse Trendelenburg position with the right side elevated, the foreign body remained in the right ventricle during the third cardiomyotomy, when it was successfully removed. Reoperation in this case gave a valuable opportunity to note the manner of healing of the myocardial incision. The myocardial scar was firm and well healed six months after the original incision, a fact that to Harken offers assurance that the injury to the myocardium caused by the incision and exploration of the ventricle is not significant.

The cases previously referred to and subsequent ones represent 138 patients and one hundred and forty-three operations. There were no deaths.

ACUTE PERICARDITIS

Streptococcus viridans is rarely encountered as the causative agent in purulent pericarditis. Hargrove¹⁹

reports a case in a sixteen-year-old boy with acute pericarditis resulting from a *Str viridans* septicemia that followed an upper respiratory infection. The organism was twice found in cultures of blood and pericardial fluid. The author suggests that electrocardiograms be made during septicemia, pneumonia and osteomyelitis if there is a suspicion of pericardial disorder. In the case reported, pericardiocentesis and electrocardiography indicated acute pericarditis. The patient was treated by aspiration and sulfanilamide, but the disease ran a stormy course and the outcome was at first doubtful, although there was an eventual recovery.

Wise and Shafer²⁰ report a case of pericardial effusion secondary to lobar pneumonia in a woman of thirty-one. Sulfadiazine and intramuscular penicillin had no effect on the lesion, but there was dramatic response to the intrapericardial injection of penicillin following pericardiocentesis and the removal of 70 cc of turbid blood-tinged fluid. A dose of 40,000 units of penicillin in 30 cc of normal saline solution was introduced directly into the pericardial cavity. Within sixteen hours the temperature dropped to normal. Penicillin was continued in decreasing doses intramuscularly for four or five days.

The number of cases of suppurative pericarditis treated by the intrapericardial instillation of penicillin has not been sufficiently large to permit any valid conclusions concerning the efficacy of this treatment. Undoubtedly, certain patients are cured by this method alone, as is true in cases of empyema thoracis, particularly those with a nonputrid empyema. As has been reported by a number of observers,^{21, 22} however, in the treatment of empyema with penicillin one may sterilize the fluid or pus by vigorous therapy, only to see a recurrence within two weeks. In other cases, the persistence of thick pus and fibrin clots, even though sterile, with consequent organization and thickened pleura, renders the expansion of the collapsed lung impossible or at least subject to long delay. It has therefore been recognized that persistent purulent accumulations in the pleura, even though sterile, should have surgical drainage. I have had the same experience in the treatment of empyemas complicating pulmonary resections, and Lynch and I have found this to be true in the treatment of putrid empyema.²³

If the same situation obtains with regard to intrapericardial penicillin therapy, the patient should sooner or later present evidence of constrictive pericarditis. Patients who have had such therapy should therefore be carefully observed so that their status in this regard may be evaluated.

Urschel et al²⁴ discuss 8 cases of acute pericarditis that they observed during a period of three months. They devised a graph to correlate the heart size, total T-wave deflection, total elevation of the RS-T segment, pericardial friction rub and temperature. Judging from the cases observed, there is no sig-

nificant electrocardiographic difference in the pericarditis caused by rheumatic fever, tuberculosis or pneumococcal or meningococcal infection

Acute pericarditis simulating myocardial infarction is discussed by Wolff²⁵ He states that pericarditis unassociated with other diseases may be characterized by pain resembling that of acute myocardial infarction, and that great care must be used in differential diagnosis, since treatment and prognosis of the two conditions are markedly different. In the several cases of acute pericarditis described by the author, the correct diagnosis was established by the careful study of clinical, laboratory, electrocardiographic, teleroentgenographic and fluoroscopic data

CONSTRICTIVE PERICARDITIS

The use of partial pericardiectomy and epicardiolysis in 24 cases of constrictive pericarditis is discussed by Harrington²⁶ The two most frequent conditions with which constrictive pericarditis is likeliest to be confused clinically are cirrhosis of the liver and congestive heart failure from intrinsic cardiac disease In most cases, however, the subjective symptoms of constrictive pericarditis are sufficiently characteristic so that when they are correlated with the physical and laboratory findings a definite diagnosis can be made

The laboratory findings are extremely valuable in establishing a diagnosis The venous pressure is elevated above normal The circulation time of the blood is increased The tests of hepatic function indicate a varying degree of hepatic damage, which depends to some extent on the duration of the disease. Roentgenologic studies of the heart in cases of constrictive pericarditis usually show it to be normal or smaller than normal It is never markedly enlarged or segmentally dilated, as in congestive heart failure from intrinsic cardiac disease and hypertensive heart disease The presence of calcareous plaques in the pericardium is noted frequently This always suggests a constricting pericardium, but calcium may occur in the pericardium without other findings of constrictive pericarditis

In the 24 cases reported by Harrington, the operative mortality was 25 per cent Of the 18 patients who recovered from operation, 9 were considered cured in the sense that subjective symptoms were relieved and the patient was able to resume his former occupation or to engage in some other useful one. The improvement in 2 more cases had approximated a cure In 2 other cases in which operation was recent, improvement had been progressive Thus, 13 of the 24 patients may eventually be considered as cured Of the remaining 5 patients who recovered from the operation, 2 had shown moderate improvement and 3 had died Two of these deaths were due to continuation of the disease, and 1 was due to pneumonia

A vexatious problem that continues to confront

the thoracic surgeon is the one presented by the patient who has the symptoms of progressive cardiac compression resulting from active tuberculous pericarditis The evidence that has accumulated in recent years suggests that in many cases constrictive pericarditis is caused by tuberculosis, but in many cases of tuberculous pericarditis, after the subsidence of the effusion, the onset of progressive compression of the heart becomes evident while the tuberculous lesion is still active, and long before the patient may be considered to have chronic constrictive pericarditis Under these circumstances, if operation is undertaken, a grossly thickened pericardium may be resected, but of necessity a layer of organizing fibrinous exudate is left adherent to the epicardium, and little if any improvement results I have recently had such an experience Partial pericardiectomy was successfully performed, but after a slight transitory improvement the patient died six weeks after operation from a continuation of her disease Operation was performed with reluctance, and only because the patient was progressively going downhill, although the cardiac pericardial shadow was becoming smaller

Blalock and Levy²⁷ discussed a series of these patients a few years ago and came to the conclusion that one should operate only when it appears that the patient will die if something is not done Beck²⁸ is of the same opinion

CONGENITAL DEFICIENCY OF THE PERICARDIUM

Rusby and Sellors²⁹ describe a case of partial deficiency of the pericardium associated with a solitary bronchogenic cyst, both on the left side, in a girl of ten Eighty such cases have been reported in the literature, but this is only the third case to be recognized during life, and the only one to be carefully studied at operation Uneventful recovery followed removal of the cyst. The authors believe it likely that partial left-sided deficiency of the pericardium is due to abnormal development, with premature atrophy of the left duct of Cuvier

OTHER INDICATIONS FOR PERICARDIOTOMY

After enumerating the standard conditions demanding pericardiectomy, Neuhoof³⁰ suggests its employment for various other conditions, some of which were encountered in the course of thoracic operations undertaken for noncardiac lesions

In a number of cases of carcinoma of the lung, there was considerable doubt at exploratory thoracotomy regarding the extent of hilar-node involvement, particularly so when the lung was broadly adherent posteriorly and when the tumor in the lung abutted on the posterior mediastinum Pericardiectomy and exploration within the sac supplied the information In another case, a carcinoma of the lung at first appeared to be inoperable because of fixation at the mediastinum and invasion of the pericardium Exploratory pericardiectomy revealed

the extent of the invasion, and liberal sacrifice of the pericardium permitted successful pulmonary resection. I have used this maneuver on several occasions for similar indications and have found it useful.

In the discussion of Neuhof's paper, Haight³¹ cited a case in which he resected a large segment of the pericardium so that he might successfully perform pneumonectomy for a bronchogenic carcinoma that was invading the pericardium. Troublesome herniation of the heart resulted in shock if the patient lay on his back or on the operated side postoperatively. It was necessary to keep the patient inclined toward the contralateral side for some days after operation, but eventually he became stabilized, and three years after operation he showed no evidence of cardiac embarrassment.

Neuhof³⁰ also suggested incision of the pericardium and retraction of the pulmonary artery mesialward in cases of patent ductus arteriosus complicated by subacute endarteritis, so as to facilitate exposure of the deep surface of the ductus. Jones,³² however, believes that there is a disadvantage in opening the pericardium in these cases, because the trickle of pericardial fluid obscures the field of dissection.

Graham³³ briefly describes the case of a woman who had a recurrence of a carcinoma of the breast in the pericardium, with massive bloody pericardial effusion that required frequent tapping. By the simple procedure of removing some of the pericardium and permitting the recurring effusion to drain into the left pleural cavity, the patient was

kept perfectly comfortable for a period of two years, when she died of further recurrences. Graham emphasizes the simplicity of the procedure and the great comfort that it gave to this patient.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, *Editor*

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 32161

PRESENTATION OF CASE

A forty-one-year-old truck driver entered the hospital because of a mass in the left upper quadrant of the abdomen.

Five months before admission the patient was referred to the Out Patient Department for study of an albuminuria that had been discovered during an examination for life insurance. In the clinic his urine was repeatedly negative for albumin, although a trace was found on one occasion. A hard, movable mass was found in the left upper quadrant that extended from near the midline into the left flank and from the costal margin downward for 8 cm. It was nontender and moved with respiration. It had not caused symptoms. The liver border was palpated 3 cm below the rib margin and was separate from the mass. There were external hemorrhoids, but no visible abdominal veins. Examination of the blood was normal except for a slight eosinophilia (8 per cent). X-ray examination revealed a large soft-tissue shadow overlying the left kidney and displacing it somewhat laterally. The spleen looked normal. There was distortion of the superior calyx of the left kidney following an intravenous pyelogram, but owing to the obscuring shadow, this was by no means definite. A barium swallow failed to indicate esophageal varices. The blood nonprotein nitrogen, total protein and albumin-globulin ratio were normal. Bromsulfalein excretion was normal, and the cephalin-flocculation test was negative. The only significant facts in the past history were that he regularly consumed a half pint of whisky every two days. He had never been out of this country. The patient refused immediate operation.

About four months later he began to have occasional slight, nonradiating pains in the region of the mass, lasting from two to three minutes each. He then entered the hospital for operation.

The physical findings were not changed. Examination of the blood showed 4 per cent eosinophils and was not otherwise remarkable. The urine gave a ++ test for albumin, and a concentration test showed a maximum specific gravity of 1.018. A gastrointestinal series demonstrated a large pressure defect in the lesser curvature caused by a mass that

displaced the stomach laterally, downward and forward (Fig 1), the ligament of Treitz was displaced, but there was no deformity of the duodenum. A barium enema was negative. A cholecystogram showed the gall bladder to be normally outlined. There was no blood in the stool.

An operation was performed on the fifteenth hospital day.

DIFFERENTIAL DIAGNOSIS

DR WALTER GARREY. Apparently this man was machine-processed in an insurance examination in which a urinalysis was done before a complete physical examination. Albumin was found in the

FIGURE 1

urine, and he was then sent to the Out Patient Department, where physical examination showed a hard movable asymptomatic mass in the left upper quadrant. Perhaps this would be a good time to see the x-ray films.

DR JAMES R LINGLEY. This is a plain abdominal film showing the mass, which fills almost the entire left upper abdomen. This is a pyelogram showing rather poor filling of the pelvis and calyces on the left side, probably due to pressure from the mass rather than to intrinsic involvement of the kidney. One can trace the kidney shadow through the mass.

quite easily. The colon shows no evidence of intrinsic disease, although the splenic flexure is displaced laterally and somewhat posteriorly by the mass. The gastrointestinal examination shows this large pressure defect on the lesser curvature of the stomach, which involves practically all the lesser curvature and has caused marked displacement of the stomach toward the left. The mucosa over this area looks normal, in other words, I can see no evidence of actual mucosal invasion. The chest plate is negative.

DR GARREY: I had three questions to put to Dr Lingley, he has already answered two of them. One was whether the kidney outline was visualized and was entirely separate from the mass. It was. The second question was whether the mucosal pattern was seen clearly down the entire length of the mass. It was. The third was whether there was any calcification in the mass.

DR LINGLEY: There is none.

DR GARREY: I am afraid that we do not get much help from the x-ray studies. There was a mass, but I am not even sure what organs were involved. The mass was contiguous to the kidney, liver, spleen, retroperitoneal tissues and root of the mesentery. According to the symptoms, it was increasing in size rather slowly. I cannot imagine any infectious process that would behave this way, with the possible exception of hydatid cyst. This man had not lived in Iceland or the Antipodes, and despite the slight eosinophilia, I do not believe that we can hazard such a diagnosis. The picture certainly does not fit that of a syphilitic liver, so I think we have to assume that the mass was on a congenital or neoplastic basis. Apparently the men in the Out Patient Department thought that the patient possibly had cirrhosis and that the mass might have been derived from the liver, perhaps a primary liver-cell neoplasm. The majority of hepatomas and cholangiomas arise in a cirrhotic liver, I think the figure is around 85 per cent. Is that correct?

DR TRACY B. MALLORY: Around here.

DR GARREY: But we have no evidence of cirrhosis. As a further interesting exercise in trying to arrive at a diagnosis, a peritoneoscopy might have been done and even a gastroscopy. A peritoneoscopy probably would not have shown the tumor directly, since it appears to have been located behind the stomach and lesser omentum and mesocolon.

DR MALLORY: A peritoneoscopy was done. Would you like to have the information?

DR GARREY: Peritoneoscopy would be worth while on the remote chance that this man had dissemination of a neoplasm and also to rule out the liver disease, but I venture to guess that it was not helpful in telling anything about the primary tumor.

DR MALLORY: The gall bladder was visualized. The peritoneal cavity appeared normal, except in the left upper quadrant, where a mass could be

seen just to the left of the greater curvature, between it and the spleen. The latter could not be visualized. The mass had a grayish-blue tinge, was covered with thin omentum and appeared to be cystic. It was not attached to the abdominal wall. There was no lobulation.

DR GARREY: Very wisely no biopsy was done, since if it were a cystic mass they did not want to spill material freely into the peritoneal cavity. I am very much interested in the physical finding of mobility, which makes the diagnosis all the harder to me. They speak of the mass as being movable in the first examination, and also that it moved with respiration, and again in the examination in the hospital four months later they mention that the mass was movable. The most probable mass in this area that has this characteristic position, size and symmetry is a cyst of the pancreas. We get no lead from the history. There was no trauma, and no biliary tract disease, which might have predisposed to a pseudocyst. A rather small percentage of pancreatic cysts are movable. The nearer they are to the tail of the pancreas and the more protic the patient, the likelier the mobility. Pancreatic cyst seems to be a strong possibility, although the patients with pancreatic cysts whom I have seen have had more pain than this man appeared to have, provided that the tumors had reached this size. I assume that the albuminuria was due to pressure on the left renal vein and kidney. This has been reported in an occasional case.

I do not believe that we are dealing with a particularly malignant situation because the man had no constitutional symptoms or signs. He did not appear to have run downhill after this five-month period. If he had a solid neoplasm of a disseminating, highly malignant character, I should expect that some other finding would have been manifest by this time. I do not believe that, with the mobility that they have emphasized, a retroperitoneal neoplasm, a sarcoma, is likely, or a large fibrosarcoma. This does not appear to have had the character of a lymphomatous tumor; it was not nodular, and it appeared symmetrical and cystic, both in the x-ray films and at the time of peritoneoscopy. There are rare tumors that may arise in the space behind the stomach—hemangioendothelioma, dermoid cyst, a cyst containing sebaceous material and tumors of neurogenic origin. I am driven away from virulent neoplasm and incline more and more to the supposition that this was a relatively benign lesion occurring in tissue at the root of the mesentery or possibly in the pancreas. Fifteen days were spent in studying this man in an attempt to make a diagnosis. They also were groping for any concurrent disease that might have given a lead to the diagnosis, but they wisely ruled it out.

My first hunch is pancreatic cyst, either a pseudocyst or a cystadenoma. My second hunch is some

are but relatively benign tumor occurring in the same area, possibly a cyst of congenital origin high in the mesentery, although the location was higher than it usually is in cases of this sort. I think that they probably had to end up by doing what is recommended by one of the late Dr G W W Brewster's dictums, which some of you may remember He urged, that if one found trouble, to cut over it

Dr. MALLORY Dr. Volwiler, you studied this patient on the ward Have you any comment?

Dr. WADE VOLWILER I saw him with the third-year medical students in the Out Patient Department, and we reached no definite decision We thought that the likeliest diagnosis was pancreatic cyst.

Dr. CLAUDE E WELCH It took Dr Garrey only twenty minutes to make the wrong diagnosis, but it took us over two weeks The albuminuria, which Dr Garrey was somewhat interested in, turned out to have no significance So far as the tumor was concerned, we thought that it was a pancreatic cyst, because it was somewhat spherical and therefore probably represented encysted fluid rather than a solid tumor On entering the abdomen we found that this was a solid tumor tightly attached to the wall of the stomach As a matter of fact it was impossible to separate the stomach from the tumor There was no attachment elsewhere We therefore had to proceed with a subtotal gastric resection We sent for a pathologist to look over the specimen as soon as it was removed, because we were interested in the fact that large, probably hyperplastic, lymph nodes extended up the left gastric artery We wanted to be sure that the line of resection, which was close to the esophagus, was free of disease The pathologist's opinion was that it was a benign tumor

CLINICAL DIAGNOSIS

Cyst of pancreas

DR GARREY'S DIAGNOSIS

Cyst of pancreas

ANATOMICAL DIAGNOSIS

Neurinoma of stomach.

PATHOLOGICAL DISCUSSION

Dr. MALLORY The tumor was a benign spindle-cell tumor of the stomach There might be some argument whether to classify it as a leiomyoma or as a perineurial fibroma I personally believe that it was the latter Its apparently cystic character was due to extreme vascularity It was so vascular that when we first saw the section the possibility of angioma suggested itself to our minds There was no extension of the tumor beyond the point of actual attachment to the gastric wall, and I think that there is no question that cure has been achieved

Dr. WALTER BAUER In retrospect, would the radiologist interpret the films any differently?

Dr. LINGLEY I should still think that it was a pancreatic cyst

CASE 32162

PRESENTATION OF CASE

A fifty-year-old man entered the hospital because of stomach pain

Fourteen months before admission the patient first began to have crampy midepigastic pain that came on three or four hours after each meal He consulted his physician, who obtained a gastrointestinal series that was said to have demonstrated a stomach ulcer He was put on a liberal, low-fat, bland diet and given "powders and white liquid" to take between meals On this regime he obtained almost complete relief for seven or eight months, when he had a recurrence of postprandial pain, which persisted despite the powders but was relieved by food One month before admission he had another gastrointestinal series, following which he was told that he would have to have his stomach removed He belched frequently and felt epigastric fullness and vague uneasiness after meals On a few occasions he induced vomiting because of distressing fullness The bowel movements were regular No bloody or tarry stools were noticed

The physical examination was negative except for a walnut-sized indirect inguinal hernia

The temperature, pulse and respirations were normal, the blood pressure was 110 systolic, 70 diastolic

The hemoglobin was 15.8 gm per 100 cc The urine was normal A gastric analysis showed no free hydrochloric acid in the first specimen, and 27 and 15 units, respectively, in the second and third specimens

X-ray examination of the stomach showed a marked degree of spasm of the antrum At the mid-portion of the lesser curvature there was a shallow collection of barium, which might have represented a flat crater The first portion of the duodenum was constantly deformed at its apex, no crater was found in that region There was a 1-cm diverticulum projecting medially from the second portion of the duodenum The heart and lungs were normal by x-ray examination

An operation was performed on the fifth hospital day

DIFFERENTIAL DIAGNOSIS

Dr. WADE VOLWILER I infer that this man was moderately obese, since the only reason for giving a low-fat diet to a patient with simple ulcer is to avoid a gain of weight during a program of frequent feedings

The center of interest here lies in the identity of this vague questionable lesion in the lesser curvature, and I think that we should have 'an x-ray opinion first. I should like to ask several specific questions. Can we assume that this duodenal deformity represents the crater of a benign ulcer at some time in the past? Can this vague lesion in the lesser curvature be interpreted in one of three ways—a scar following the healing of an ulcer in that area, a flat shallow crater or just a collection of barium between hypertrophied gastric rugae?

DR JAMES R LINGLEY I did the examination on this particular patient, and those were the exact questions that I had in mind while doing it. I had great difficulty in determining whether or not this lesion in the lesser curvature was a crater. The most remarkable thing about the stomach was the extreme spasm of the antrum. Trying to find some cause for the spasm, I studied the area on the lesser curvature extremely carefully and found a lesion 1.5 cm in size where the barium tended to puddle out and form a shallow crater.

DR VOLWILER Was there rigidity over that area?

DR LINGLEY That was difficult to determine because the stomach was high, lying under the costal border, and we could not palpate it. There was no peristalsis in that region. I thought that it was a crater, probably an extremely shallow one, representing an almost healed ulcer. The patient showed a constant deformity of the apex of the duodenum and a small diverticulum in the second portion.

DR VOLWILER The duodenal picture probably represents the healed stage of a benign ulcer.

Let us go back to the present illness, which began with the typical symptoms of peptic ulcer, and which disappeared almost completely in eight months on a fairly satisfactory ulcer regime. I am going to assume that during that time the original ulcer had healed almost completely, if not completely. We do not know where the ulcer was, but it could have been either a duodenal or a gastric ulcer. I think that we should take the patient's statement at face value and assume that it was a gastric ulcer and that it had probably originated at the site of the present defect. During the two months before entry there was a sudden change of symptoms, which is significant. Diffuse hypertrophic gastritis could have produced the recent symptoms of this man and might have been difficult to demonstrate by x-ray. It can occur in a localized form, but it is seldom observed on the midportion of the lesser curvature and the localized form usually does not give rise to such extensive symptoms. I believe that the development of such a process, leading to the symptomatology that existed here during the time that the patient was following a fairly good regime, is highly unlikely, and I therefore shall dis-

card it. I shall also discard a scar as an explanation of the lesion, because that, of course, could not explain the symptoms.

We should perhaps mention cholecystitis, cholelithiasis and even subacute recurring mild pancreatitis as an explanation of the symptoms. There is no evidence for them, however, and we should focus our attention on the stomach. I am not sure whether there was an ulcer crater. But regardless of that fact, I think that, in view of the symptoms, the most logical explanation for the lesion is a small, slowly growing, infiltrating carcinoma. I say that in spite of the facts that this patient probably was moderately obese, that he had previously had a benign lesion in the duodenum, that the stomach produced free acid and that the x-ray defect was questionable. This patient certainly should have been operated on. A preoperative gastroscopy might have given valuable information, but regardless of what was found, I believe that the stomach should have come out. This may have been one of those occasional extremely difficult cases in which neither the surgeon nor the pathologist on gross examination can decide what the lesion is. It may have been only the microscopical examination that revealed the true identity of the lesion.

CLINICAL DIAGNOSIS

Gastric ulcer

DR VOLWILER'S DIAGNOSES

Carcinoma of stomach
Old benign duodenal ulcer

ANATOMICAL DIAGNOSIS

Carcinoma of stomach

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The patient was operated on, and a subtotal gastric resection was performed. We found on the lesser curvature a localized area, slightly over 2 cm in diameter, where the mucosa appeared thicker and firmer than elsewhere, with a somewhat different translucence and color, at one margin there was a shallow erosion. The wall of the stomach was thickened and indurated under this area of altered mucosa. The gross appearance, however, was essentially that of a healed ulcer rather than of a neoplasm. When the microscopic preparations came through it became evident that the entire area of altered mucosa showed a carcinoma in situ. At one single spot tumor cells had invaded the submucosa, and two or three glands had penetrated a short distance into the muscularis. Several small lymph nodes were examined. All were negative, as one would expect with such an early lesion.

THE INADEQUACIES OF MEDICAL CARE

II THOSE CONCERNING ITS DISTRIBUTION AND COST

OF UTMOST interest at the moment in matters pertaining to medical care are its distribution and cost. It is a well recognized fact that many persons fail to receive adequate medical care either because it is unavailable or because they are of the opinion that they cannot afford it. At times this is inexcusable, since the means are at hand provided that the person knows how to obtain them. On the other hand, in the majority of cases there is a just complaint. In many areas facilities are lacking, in others they are inadequate, and in all certain fees for medical care are out of all proportion with the income of the patient.

Obviously legislation should be directed toward the relief of sections that lack facilities for medical

care. Hospitals and health centers should be constructed and equipped by the state, with the assistance of federal grants-in-aid, and these in turn would have a tendency to attract properly qualified physicians. To be sure, the economic status of any particular section may be such that the physician is unable to obtain a living wage, but that again is a responsibility of the state, which should guarantee a reasonable income by supplementing what he is able to earn with a salary or retaining fee.

Inadequate care involves poorly trained physicians, those who had proper training but have failed to keep up with medical advances, a scarcity of qualified specialists and lack of proper hospital facilities. The first two concern the quality of medical care and the last has to do with hospital rather than medical care, all of which will be discussed in subsequent editorials. Lack of well trained specialists in any given section is largely a matter of insufficient incentive for the specialist to practice there, physicians of this type naturally tend to congregate in large or moderate-sized cities, where well equipped hospitals are located and where they are satisfactorily paid for their services either by salaries or by fees. To persuade them to settle in sparsely settled areas or in those of low economic status again will require state aid.

The matter of cost of medical care naturally receives the topmost attention from the public. By and large, the indigent, particularly those who reside in or near urban areas, now receive reasonably good medical care with little or no cost, and those with low to moderate incomes are capable of handling the expense of minor illness with slight financial inconvenience. But the consequences of a major medical or surgical illness, including loss of wages, is a catastrophe for which few of the latter group have provided.

No doubt much needs to be done to improve the medical care of the indigent in areas other than urban. Many of the handicaps to this type of care would be removed if hospitals and health centers were made available, the cost being met by state funds, with the assistance of federal grants-in-aid.

A great deal has been written concerning the high cost of medical care. There is no doubt that this expense has risen tremendously in recent years, but

so, too, has that for almost everything else. On the other hand, what appear to be large fees do not necessarily mean a high net income to the physician. His training, particularly if he is a qualified specialist, represents a considerable capital outlay, which often must be repaid over a period of years, furthermore. His actual cost of successfully practicing medicine is many times larger than that of the old family doctor. Hospitalization and expert nursing care also add appreciably to the expense of a serious illness, but no one can deny that the patient who is obliged to undergo a gastrectomy is better off in a modern hospital than he would be if he were operated on lying on a door in the kitchen or back parlor. No doubt the cost of serious illness has risen, nor does there seem to be any logical way in which it

can be appreciably lowered in any individual case. All of which means that persons in the low-income group and even in the moderate-income group must set aside money in anticipation of catastrophic illness. In other words they must insure against it just as they insure against fire or burglary. Compensation for loss of wages due to illness might well be included among the benefits provided by the Social Security program.

It seems likely that the cost of good medical care can be lowered by group practice. In the obscure case, the opinions of various specialists can obviously be obtained for less actual cost and with less inconvenience to the patient if these men have banded together in a group than if they are practicing as individuals. Outstanding examples of this type of organization are the nationally known large private clinics and those connected with teaching hospitals, and there are hundreds of small groups scattered throughout the United States, particularly in the Mid-West and South. This type of practice has much to offer, and it will probably become

more popular in the near future than it has been in the past.

In summary, the inadequacies of the distribution of medical care are largely the concern of government, although ignorance of the public concerning available facilities is far from a negligible factor. The high cost of medical care can undoubtedly be somewhat lowered by group practice, but there

appears to be no way of eliminating the expense of catastrophic illness, other than by insuring against it.

MASSACHUSETTS MEDICAL SOCIETY POSTWAR LOAN FUND

The Postwar Loan Fund has been set up, and all discharged medical officers who were members of the Massachusetts Medical Society in good standing at the time of their entry into the service may apply for loans from this fund. For further information apply to

TEACHING HOSPITALS

IN A recent address, Dr. Alan Gregg,¹ director for the medical sciences, Rockefeller Foundation, discussed the place of the teaching hospital in the training of medical students and nurses, for

the specialized and advanced training of physicians and for the advancement of medical knowledge. In addition, he emphasized what may be of equal or even greater importance to the public who supports these hospitals, namely, that the teaching hospital provides the best type of care for the patient. In speaking about the patients whose cases are studied by medical students and their teachers, Dr. Gregg said in part:

What an amazing misconception about this procedure is rampant among most laymen! They think that when they consent to be part of a demonstration in a clinic, for teaching purposes, they are conceding something of their comfort and well-being to the professional zeal of young doctors. The exact opposite is true. When a patient consents to this procedure, his case receives the most careful, the most accurate and most modern treatment. Actually, it has all the advantages of an early consultation. So few people understand this. So many, especially of the middle class income group, ought to realize this. They should know that to consent to be used for teaching is to display the most enlightened self-interest.

In a comment on President Truman's special message to Congress advocating compulsory national medical insurance, the Committee on Medicine and

the Changing Order of the New York Academy of Medicine² made some pertinent suggestions. To raise the quality and to round out the scope of medical care extended under any system of payment, the committee favors not only a number of revisions in medical education but also the gradual extension of group practice. In this connection, it is stated

It is essential, moreover, that medical group practice units be organized also in relation to teaching hospitals, since an extension of prepaid medical care to all people of low income must inevitably have important repercussions on medical education and research. The medical schools, for their part, must change their methods if they are to train doctors for a new form of medical care, and no form of medical care can afford to neglect the advantages to the patient of teaching and research.

That the teaching hospital must provide the best type of medical care for the patients can readily be appreciated on the briefest reflection. The patient whose case is used for teaching *must* receive the best of modern care. Everybody from student through intern and resident to visiting physician must be on the alert and aware of the up-to-date methods of diagnosis and treatment. The alternative is to lay oneself open to censure or to lose dignity and respect.

Perhaps the greatest possibilities for abuse by the medical profession exist in the practice of surgery or of the surgical specialties. In small hospitals and in strictly private hospitals, or even in the large public hospitals, if there is not a feeling of responsibility on the part of the surgeon to justify every step, and also the willingness on his part to take the time and trouble to keep in touch with medical progress, the patients suffer. This, however, is not limited to surgeons. One can readily imagine the abuses that are possible in the care of neuropsychiatric cases by unscrupulous physicians when the management of their cases is not subject to review and justification.

The Veterans Administration, in its recent reorganization, has accepted the concept of the teaching hospital as the only available means of establishing and maintaining the highest quality of medical service. Teachers from medical centers are to be chosen to staff its hospitals on a part-time basis. They are expected to provide the incentive for the resident staff to study their cases adequately,

so as to be able to provide the best of medical care. The close association of interns and residents with these teachers will also provide inspiration to the younger men to sustain interest, to follow their cases closely and to correlate their findings and thus be in a position to improve and advance the quality of service that they offer.

In hospitals whose staffs are not closely allied with medical schools, promotions within the staff are based entirely on seniority. It is obvious that when such promotions are made without considering the professional qualities and attainments of the physician the quality of the care that the patients receive is apt to suffer. Naturally, those who would otherwise rise by seniority rather than by attainment are likely to resist any attempt by medical schools to deprive them of their rights to promotion. The sole duty of medical schools is to provide good clinical instruction, and this predicates the best medical care for the patient and the choice of the persons best qualified to give such care. Thus, resistance to change was undoubtedly met by the new heads of the Veterans Administration when many of the less qualified among the senior officers had to be replaced.

Administrators and trustees of public hospitals and their medical staffs would do well to take the cue from the Veterans Administration. Needless to say, the least qualified among the staff members will be relegated to less responsible positions when a medical school affiliating with a hospital is given a free hand in the selection of teachers and a determining role in promotions within the staff. When a hospital staff resists such a move as an encroachment on its prerogatives, it is paramount to an admission either of inferiority or of a lack of interest on the part of its members. In other words, such an attitude must be interpreted as indicating either that they are unsuited for the positions or that they are not sufficiently interested in the welfare of their patients and of the hospital and in the improvement of medical practice to take the time and to put in the extra effort that is required of the members of the staff of a teaching hospital.

Both the hospital and the medical school have added responsibilities when they become affiliated, and these all accrue to the benefit of the patient.

The hospital must provide the facilities for the best of medical practice, and these are always under the scrutiny of the students and their preceptors. The latter must always be on their toes and keep up to date. Medical schools, on the other hand, have the responsibility of seeing that they make the best choice and that they recommend promotions solely on the basis of merit and achievement.

ANNUAL MEETING OF THE COUNCIL

The annual meeting of the Council will be held in the Georgian Room of the Hotel Statler, Boston, on Tuesday, May 21, 1946, at 7:00 p.m. This meeting will be preceded by the Cotting supper which will be served in Parlors A and B of the same hotel at 6:00 p.m.

Business

1. Presentation of record of the stated meeting of the Council held February 6, 1946. To be published in the *New England Journal of Medicine*, issue of May 2, 1946.
2. Reports of standing and special committees.
3. Election of officers and orator.
4. Appointment of committees for ensuing year.
5. Such other business as may lawfully come before the meeting.

MICHAEL A. TIGHE, *Secretary*

SUBCOMMITTEE ON VETERANS' AFFAIRS, POSTWAR PLANNING COMMITTEE

In the course of its investigation of the needs of medical officers who had returned from the armed forces, the Subcommittee on Veterans' Affairs soon stumbled on the serious problem of early telephone listing for doctors reopening their offices. The committee pursued this subject as soon as possible in order to get early action thereon. A preliminary report of the committee's findings is as follows:

The next telephone directory will be published for the Boston District in December. Owing to the paper shortage this is the earliest date that the Government will permit publication of a new directory. The New England Telephone and Telegraph Company is fully aware of the seriousness of this problem, not only for doctors but also for other professional men. It has canvassed means to solve it and has taken the following steps:

- (1) A leaflet will accompany the April telephone bills urging subscribers to make use of Information Service for numbers that they cannot find and pointing out that since the last directory was published there has been a gain of 72,000 phones in the Boston area (225,000 in the total area served).

(2) It has expanded Information Service and is continuing this expansion as fast as new operators are trained. In the Boston area there will eventually be an increase of 15 per cent (128 operators) in the personnel of this service.

(3) Beginning about April 1, the company will stress the use of Information Service in advertising especially in the daily papers. This will be a regular campaign and the company accepted the suggestion to stress the use of this service in the advertising in connection with the phrase "your doctor" or "your attorney who has returned from the services."

(4) The company welcomes any suggestion as to how to make doctors' numbers more readily available to the public, subject to the limitations outlined above. At the present time every number is in the hands of Information Service within twenty-four hours of the installation of the telephone.

(5) Doctors can help this campaign by telling their patients to use Information Service for numbers they fail to find in the directory.

The company has been most courteous and patient and has explained to us in detail many of the difficulties involved and the reasons that led them to adopt this as the only solution to the present dilemma.

G. PHILIP GRADFIELD, *Chairman*

TREASURER'S REPORT COVERING REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to district societies for 1946:

The Council voted to distribute the sum of \$4000 to district societies. The total number of payments of annual dues received by the Treasurer by March 1, to be counted for the refund, was 3965. Therefore the refund to the district societies for each paid fellow is \$1.009.

The following table gives the number of payments, as of March 1, and the refund to each district as of April 1:

DISTRICT	NUMBER REPORTED PAID	REFUND
Barnstable	39	\$39.32
Berkshire	104	104.88
Bristol North	57	57.48
Bristol South	155	156.36
Essex North	150	151.31
Essex South	217	218.91
Franklin	35	35.29
Hampden	260	262.30
Hampshire	61	61.51
Middlesex East	114	114.99
Middlesex North	102	102.88
Middlesex South	810	817.25
Norfolk	699	705.26
Norfolk South	107	107.92
Plymouth	114	114.99
Suffolk	532	536.75
Worcester	332	334.95
Worcester North	77	77.65
-	3965	\$4000.00

In 1945, for comparison, the total number of payments for the refund was 3297.

ELIOT HUBBARD, JR., M.D., *Treasurer*

MEDICOLEGAL ABSTRACT

Relation of Patient and Physician Liability for malpractice. The plaintiff alleged that the defendant, a dentist, had broken off a drill and hypodermic needle in his jawbone, that these were the cause of his illness and considerable medical expenses to which he had been put, that the defendant knew that the drill and the needle were there and

that he had fraudulently concealed the facts from the plaintiff

The defendant made a motion to dismiss by reason of the acts having taken place more than two years before the suit was begun

The Arizona court held that the dentist had a duty to disclose the facts to the plaintiff and that his failure to do so was such fraud as to prevent the running of the Statute of Limitations until the facts fraudulently concealed became known — (*Acton Morrison*, 155 Pac [2d] 782, Jan 29, 1945, Arizona)

This case may be distinguished from a Massachusetts case in which it was alleged that the defendant, physician, left gauze in the plaintiff during an operation performed more than two years before the action was brought. The gauze was not discovered until shortly before the suit was begun. There was no allegation that the doctor knew the gauze had been left in. The Supreme Judicial Court holding that the action was barred by the Statute of Limitations said that there was no showing that the defendant had fraudulently concealed the facts — (*Capucci v Barone*, 266 Mass 578 [1929])

It is noteworthy that the court in the first case considered the relation of dentist and patient such fiduciary relation that a mere failure to disclose without any affirmative act of concealment was sufficient to constitute fraud

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

CURED CANCER CLINICS

At the moment, fourteen Cured Cancer Clinics are scheduled to be conducted during the month of April. These clinics represent a special form of teaching clinic in which only cured cases will be shown. Such teaching clinics, held at the places of meeting of the regular state-aided cancer clinics, are designed for the purpose of advising the physicians of the community regarding cancer, its symptoms, diagnosis and treatment.

The clinics will be held at Beverly, Boston (Boston Dispensary and Beth Israel Hospital), Brockton, Fall River, Fitchburg, Gardner, Greenfield, Lawrence, New Bedford, Salem, Westfield (State Sanatorium), Worcester and Wrenham (Pondville Hospital).

Information regarding the dates and times of the Cured Cancer Clinics will be provided at the regular state-aided cancer clinics or at the local district health offices

MISCELLANY

NEW PSYCHIATRY PROGRAM AT BOSTON UNIVERSITY

With the appointment of Dr William Malamud as professor of psychiatry and chairman of the Department of Psychiatry at Boston University School of Medicine, the University will undertake a program of undergraduate instruction in this field that will meet the need for providing medical students with a more extensive training

In making the announcement of the appointment of Dr Malamud, who is now director of research at the Worcester State Hospital, President Daniel L. Marsh said that the School of Medicine has recognized for a long time that the psychiatry training offered today to students in medical

schools is generally inadequate. An anonymous gift of \$30,000 from a long-time friend of the University has now made possible the expansion of this part of the school's instructional program

Under the direction of Dr Malamud, the University will inaugurate a program of undergraduate training in psychiatry that will be carried on throughout all four years of the medical-school course. Special emphasis will be placed on giving the students an increased opportunity to receive training in the diagnosis and management of the neuroses, which are now recognized as constituting a large part of all medical practice

CARE OF NONSERVICE-CONNECTED ILLNESS

Treatment in private hospitals, at government expense, of male veterans whose illnesses are not service connected cannot be authorized by the Veterans Administration, according to officials of the Boston Branch Office of the Veterans Administration. The statement was made to correct misinformation among both veterans and private-hospital authorities. Veterans whose disabilities are service connected may receive private-hospital treatment at government expense. Except in emergency cases, however, the veteran must make arrangements for such private-hospital care with the Veterans Administration prior to entering the institution.

In discussing nonservice-connected cases, the officials point out that arrangements may be made for treatment of women veterans in private hospitals at government expense if Veterans Administration hospital facilities are not available. Male veterans with nonservice-connected illnesses may be treated at Veterans Administration hospitals at government expense if beds are available in addition to those required by veterans whose disabilities are service connected

BOOK REVIEWS

The Diagnosis and Treatment of Acute Medical Disorders By Francis D Murphy, M.D. 8°, cloth, 503 pp., with illustrations. Philadelphia: F. A. Davis Company, 1944. \$6.00

There are acute episodes and emergencies in medicine as well as in surgery. The disturbing problem that confronts the physician in such acute cases is one of correct diagnosis, the rest of the battle is to follow a certain routine treatment. In this book Dr Murphy has grouped a number of such emergencies under various headings and has dealt with them masterfully. It is really a volume on differential diagnosis, although the treatment in each case is not neglected. But it is the former that presents the major problem — things are not always what they appear to be on the surface.

The discussions in general are well presented and adequate. In a few places they appear to lack somewhat in detail, but some curtailment was undoubtedly necessitated for the sake of brevity. A great deal of material and up-to-date information has, however, been crowded into this volume. Some of the discussions on differential diagnosis are excellent for clarity and presentation and reveal the true teacher. Unfortunately, for the book-buyer, medical progress is so rapid that often by the time a volume is published new treatments and remedies have come to light, for example, in the treatment prescribed for subacute bacterial endocarditis, the author does not include massive doses of penicillin, for which recent reports claim great promise. Even in this day of refresher courses, here is a valuable volume that is stimulating and refreshing.

Medical Care and Health Services for Rural People. A study prepared as a result of a conference held at Chicago, Illinois, April 11-13, 1944. 8°, paper, 226 pp., with 12 charts. Chicago: Farm Foundation, 1944. Single copies, each \$1.00, five or more copies, each 60 cents.

This book is the report of a conference held at Chicago on April 11-13, 1944, which was sponsored by the Farm Foundation for the purpose of discussing medical care and health services for rural people. Representatives of many farm organizations, governmental agencies, medical organizations, universities and voluntary organizations comprised

most of the discussant group. Every phase of the problem was given consideration. Views expressed were as divergent as the opinions of the participants.

A committee comprised of representatives of the Farm Bureau, the Farmers Union, the Grange, and the Southern Tenants in Farmers Union submitted the following recommendations:

1 That the governor of each state be asked to appoint a committee or commission to study the problems of rural health and medical care in the respective states.

2 That farm organizations be encouraged to continue study and experimentation in the field of health service, drawing upon local and national professional and civic groups, such as the associations of hospitals, physicians, public-health organizations, medical colleges and other groups.

3 That the foundation stimulate the establishment of scholarships for farm boys and girls who will study medicine and nursing and return to rural areas for practice.

4 That the foundation establish a national committee on rural health by providing technical services and information and by inviting the national farm organizations to name representatives to serve on the committee.

This book, with its large amount of information, should be of considerable interest to physicians studying medical economic problems.

Medical Uses of Soap. A symposium. Edited by Morris Fishbein, M.D. 8th cloth, 182 pp., with 41 illustrations. Philadelphia: J. B. Lippincott Company, 1945. \$3.00.

Erasmus Wilson in the middle of the nineteenth century popularized the bath by his writings for laymen on the care of the skin. Since then soap has become increasingly popular, and as one of the collaborators of this book states, "There is a trite maximum to the end that the per-capita consumption of soap is a yardstick of a nation's degree of civilization." When the busy dermatologist reviews his practice, however, and notes the large number of soap-sensitized individuals he has to treat, he wonders whether or not the per-capita consumption of soap in America is not too excessive, as a result of the propaganda of soap manufacturers.

This treatise on soap is timely but must be read rather carefully and weighed in the balance. As stated in the preface, a book of this type — written by a group of collaborators — is bound to have a certain amount of duplication. This is noted not only in the discussion but also in the illustrations. Instead of repeating illustrations, pictures of other dermatoses would have been more appropriate. The first few chapters on the chemistry of soap are excellent; in fact, the book is so well done that it is difficult to find fault.

A few over-statements might be mentioned, such as on page 63, where it states acne due to chlorinated compounds can be prevented and aided by soap and water. This does not agree with the reviewer's experience in treating such cases. With reference to page 69, most plating procedures, such as nickel plating, are done in acid baths. After reading the discussion on synthetic detergents on page 84, one would think that sulfonated oils were a distinct entity, whereas they are probably the commonest of synthetic detergents. These remarks are quoted merely to show what an excellent symposium this collection of articles forms. This is a book that should be read by everyone interested in soap, and should be a valuable addition to the library of the physician, the student and the layman.

NOTICES

ANNOUNCEMENTS

Dr. Robert J. Cataldo announces the opening of his offices for the practice of internal medicine at 820 Main Street, Waltham, and 475 Commonwealth Avenue, Boston.

Dr. Trygve Gundersen wishes to announce his return to the practice of ophthalmology at 101 Bay State Road, Boston.

Dr. Sumner D. Liebman announces his return from military service and the opening of an office for the practice of ophthalmology at 115 Bay State Road, Boston.

MASSACHUSETTS PHYSIOTHERAPY ASSOCIATION

The Massachusetts Physiotherapy Association Incorporated, which is the Massachusetts chapter of the American Physiotherapy Association, will gladly furnish a directory of its members to any member of the medical profession. Requests should be addressed to Mrs. Dorothy V. Warren, Physical Therapy Department, Massachusetts General Hospital, Fruit Street, Boston.

NEW ENGLAND OTO-LARYNGOLOGICAL SOCIETY

The regular spring meeting of the New England Oto-Laryngological Society will be held at the Massachusetts Eye and Ear Infirmary on Wednesday, May 8.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The next oral and written examinations for fellowship in the American College of Chest Physicians will be held at San Francisco on June 29. Applicants for fellowship in the College who plan on taking the examination should communicate with the Executive Secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10.

The twelfth annual meeting of the College is scheduled to be held at the Sir Francis Drake Hotel, San Francisco, on June 29 and 30 and July 1 and 2.

BOSTON GASTROENTEROLOGICAL SOCIETY

A meeting of the Boston Gastroenterological Society will be held at the Harvard Club of Boston on Wednesday, April 24, at 12 m. Dr. Reginald Fitz will deliver an address on the subject "Appendicitis and Its Complications." Luncheon will be served free to members and a nominal charge will be made for guests. Reservations may be made by telephoning the secretary, Dr. C. W. McClure at KENmore 3200.

MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS

The annual meeting of the Massachusetts Society of Examining Physicians will be held on Wednesday, May 8, in the Colonial Room of the Copley Plaza Hotel, Boston.

Dinner is scheduled for 6:30 p.m., to be followed by a round-table discussion of the Wagner-Murray-Dingell Bill, with Dr. Joseph S. Lawrence, chief public relations officer of the American Medical Association at Washington, D.C., and Dr. Allan M. Butler, of the Massachusetts General Hospital, as the chief speakers.

Because of the interest in the subject to be discussed, the society will welcome nonmembers who may wish to attend. Reservations for the dinner may be made by writing to Miss Anne Rodman, Assistant Secretary, 157 Fourth Street, Medford, Massachusetts.

NEW YORK ACADEMY OF MEDICINE

The Nineteenth Graduate Fortnight of the New York Academy of Medicine will be held October 7 through October 18, the subject being "Tumors." The program includes evening lectures, morning panel discussion, scientific exhibits and demonstrations at the Academy and afternoon clinics at leading hospitals of New York City. Complete programs will be mailed to physicians on request.

A physician who is not a fellow of the Academy may secure registration by sending his name and address, accompanied by a check for five dollars, to the Secretary of the Graduate Fortnight Committee, 2 East 103rd Street, New York 29, New York. Medical officers of the United States Army, Navy and Public Health Service, on active duty, will be admitted to all sessions without a registration fee.

THE PROBLEM OF NUTRITION IN THE POSTOPERATIVE CARE OF ABDOMINAL WOUNDS OF WARFARE*

LIEUTENANT COLONEL J E DUNPHY, MC, AUS, MAJOR STANLEY O HOERR, MC, AUS,
CAPTAIN C L DIMMILER, Jr, MC, AUS, AND CAPTAIN ROBERT R WHITE, MC, AUS

RAPID evacuation, the improved treatment of shock and skilled surgery available within a few miles of the front have made it possible to operate on many patients with abdominal wounds of an extent and gravity seldom seen in those treated in World War I. Despite this fact, the immediate postoperative mortality of 50 per cent, generally accepted as representative of the last war,¹ has been considerably reduced.^{2, 3} Most reports of experiences in this field have dealt largely with the operative and immediate postoperative periods. The complex problems in nutrition and sepsis presented by some of these patients on arrival at fixed hospitals have not been emphasized.

During the campaign in Normandy, the normal channels of evacuation for postoperative abdominal cases by-passed this unit, which received only slightly wounded men who could be promptly returned to duty or seriously wounded ones whose condition was so precarious that evacuation to the United Kingdom was impossible. In the latter group were 16 patients gravely ill with extensive abdominal wounds. These patients were selected for transfer to this unit specifically because of their poor general condition, and represent only the more complicated end results in a series of about 150 cases.

The nature and severity of the injuries are significant (Table 1). There were multiple injuries in every case. The small bowel was perforated in 9 cases, the colon in 6 cases, and the rectum in 1 case. There were liver wounds in 3 cases, a duodenal wound in 1, and a gastric wound in 1. The bladder was involved in 2 cases and the urethra in 1. In 2 cases there were combined abdominal and thoracic wounds. Ten patients had extensive soft-tissue injuries, with buttock or perineal wounds in 6 of them. There were 7 cases of compound fracture, which involved the sacrum in 4 cases and the humerus, forearm and femur in 1 case each. One patient required a high amputation of the thigh because of destruction of the external iliac artery and vein. Resection of

the bowel had been necessary in 6 cases. In 1 of them, both the ileum and the colon had been resected, and in another, three separate resections of the small bowel had been performed.

POSTOPERATIVE COMPLICATIONS

All 16 patients had varying degrees of anemia and hypoproteinemia when they reached this unit. There were 5 patients with external fistula, which involved the genitourinary tract in 3 cases and the duodenum and ileum in 1 each. Infection—retroperitoneal, peritoneal or in the wound—constituted a major complication in 12 cases. It was the cause of the 2 deaths in this group, in one case from rapidly progressing peritonitis and on the other from extensive retroperitoneal abscesses. Intestinal obstruction developed in 11 cases and required reoperation in 2 of them. There were 7 cases of jaundice. Azotemia was noted in 2 cases. Thrombophlebitis occurred in 2 cases, and was accompanied by a small pulmonary infarction in 1 of them. Vein ligation was not done in this case, and the episode did not recur. Three patients had residual pulmonary infection from an underlying atelectasis. Unexplained massive hemorrhage from the lower gastrointestinal tract occurred in a patient who had an extensive liver injury and moderate jaundice. No prothrombin determination could be done, and sigmoidoscopy and barium studies of the colon disclosed no abnormalities. Despite two episodes of bleeding, the patient steadily improved and was evacuated in good condition.

A discussion of the management of all these complications is not within the scope of this paper. Each was dealt with according to well established surgical principles. Maintenance of nutrition in certain patients presented considerable difficulty, however, and it is to a consideration of this problem that this report is directed.

NUTRITIONAL STATUS AND PARENTERAL FLUID THERAPY

At the time of admission to this unit all 16 patients were suffering from varying degrees of anemia

*From the Surgical Service of the 5th General Hospital, United States Army.

and acute malnutrition. Data on a representative number of cases are given in Table 2, which shows the amount of blood and plasma administered prior to arrival and the hemoglobin and serum protein levels on admission. It is evident that these patients would have benefited by a higher protein intake in the postoperative period prior to arrival.

Previous experience with abdominal wounds had convinced us of three facts — that profound anemia and nutritional edema develop with extraordinary

by vein precluded its use in these cases. Thus, when the caloric intake was low it became necessary to rely on small supplemental oral feedings, usually in the form of sweetened milk. These were often begun before all evidence of peritonitis or intra-peritoneal infection had subsided. Available vitamin preparations were given routinely as shown.

This regime effectively restored the levels of hemoglobin and serum protein to normal in all the patients in an average of seven to ten days. The re-

rapidity, that large amounts of protein are required to maintain a reasonable nutritional balance and that it is much better to prevent than to treat the nutritional disturbances that develop. To meet this problem a routine nutritional program for abdominal sepsis was adopted (Table 3). This regime is essentially the same as that recommended some years ago by Collier and Maddock⁴ for salt and water balance, except that it substitutes 1 liter of protein-carrying fluid for 1 liter of 5 per cent dextrose and water. It provides approximately 50 gm of protein and 125 gm of carbohydrate daily. If there is a considerable loss of salt, the total carbohydrate intake may be as high as 200 to 300 gm. The daily parenteral caloric intake may thus vary between 800 and 2000, depending on the amount of glucose given. The well known impracticability of repeatedly giving concentrated solutions of glucose

results of therapy in Cases 3 and 7 are shown in Figures 1 and 2, respectively. These are typical responses. The need for whole blood as well as plasma is illustrated in Case 7. In general, the more septic the patient was the slower was the response to therapy, but even in the sickest patients, whose cases are presented in detail below, the levels of hemoglobin and serum protein returned to normal within fourteen days.

The hazards of repeated large amounts of blood and plasma constitute an objection to this nutritional regime. In this series of 16 patients, fresh — one to seven days old — banked blood preserved in a sodium citrate-glucose mixture was used. Most of the blood was Type O. No serious transfusion reactions were encountered, and there was no evidence of massive hemolysis of either the patient's or the transfused blood. There were 7 cases in

which jaundice developed, but the available evidence indicated that severe sepsis rather than hemolysis was the principal contributory factor.⁸ In 2 cases, moderate nitrogen retention without a true renal shutdown occurred. In one of these, the transfusions were continued and recovery ensued as soon as sepsis was controlled. In the other, death occurred from generalized toxemia and sepsis. Post

general nutritional status of the patients improved only when residual infection had been eradicated.

THE ROLE OF INFECTION

The principal cause of the severe degrees of malnutrition encountered in these patients was infection. In every case in which residual abscesses were easily accessible and could be promptly drained,

mortem the kidneys were grossly normal. Although histologically there was minimal evidence of so-called "hemoglobinuric nephrosis," the changes were not sufficient to be regarded as a significant contributory factor to death.

Although our experience with repeated transfusions of Type O whole blood and pooled dried plasma was uniformly satisfactory, there is in-

rapid convalescence resulted. In all cases in which there were deep seated peritoneal or retroperitoneal abscesses that could not be well localized or readily drained, convalescence was prolonged and progressive wasting of the subcutaneous tissues occurred. This was true even in patients who were able to take fairly large amounts of food by mouth. The degree of weight loss in some patients was ap-

creasing evidence that this therapy, especially if high-titer blood is used, produces hemolytic anemia.⁶ Therefore, whenever possible, matched blood or type-specific plasma should be used. Indeed, albumin may eventually prove preferable to plasma for nutritional purposes.

In contrast to the prompt rise in hemoglobin and serum protein that occurred under this regime, the

palling, in several cases it amounted to over 60 pounds. It is therefore evident that the management of residual infection must be regarded as an essential feature of any nutritional program.

In dealing with infection, the following general principles were adopted. All localized, easily accessible abscesses were promptly drained. This was done even before the serum protein and hemo-

and acute malnutrition. Data on a representative number of cases are given in Table 2, which shows the amount of blood and plasma administered prior to arrival and the hemoglobin and serum protein levels on admission. It is evident that these patients would have benefited by a higher protein intake in the postoperative period prior to arrival.

Previous experience with abdominal wounds had convinced us of three facts — that profound anemia and nutritional edema develop with extraordinary

by vein precluded its use in these cases. Thus, when the caloric intake was low it became necessary to rely on small supplemental oral feedings, usually in the form of sweetened milk. These were often begun before all evidence of peritonitis or intra-peritoneal infection had subsided. Available vitamin preparations were given routinely as shown.

rapidity, that large amounts of protein are required to maintain a reasonable nutritional balance and that it is much better to prevent than to treat the nutritional disturbances that develop. To meet this problem a routine nutritional program for abdominal sepsis was adopted (Table 3). This regime is essentially the same as that recommended some years ago by Coller and Maddock⁴ for salt and water balance, except that it substitutes 1 liter of protein-carrying fluid for 1 liter of 5 per cent dextrose and water. It provides approximately 50 gm of protein and 125 gm of carbohydrate daily. If there is a considerable loss of salt, the total carbohydrate intake may be as high as 200 to 300 gm. The daily parenteral caloric intake may thus vary between 800 and 2000, depending on the amount of glucose given. The well known impracticability of repeatedly giving concentrated solutions of glucose

results of therapy in Cases 3 and 7 are shown in Figures 1 and 2, respectively. These are typical responses. The need for whole blood as well as plasma is illustrated in Case 7. In general, the more septic the patient was the slower was the response to therapy, but even in the sickest patients, whose cases are presented in detail below, the levels of hemoglobin and serum protein returned to normal within fourteen days.

The hazards of repeated large amounts of blood and plasma constitute an objection to this nutritional regime. In this series of 16 patients, fresh — one to seven days old — banked blood preserved in a sodium citrate-glucose mixture was used. Most of the blood was Type O. No serious transfusion reactions were encountered, and there was no evidence of massive hemolysis of either the patient's or the transfused blood. There were 7 cases in

the chest, spleen, stomach, colon and pancreas. Post-mortem examination disclosed gross leakage from all the suture lines in the multiple wounds of the stomach and colon. The other death occurred as a consequence of long-standing intestinal obstruction associated with a large undrained retroperitoneal abscess. Although the intestinal obstruction was relieved by surgery after admission to this hospital, the patient gradually lost ground and

enterostomy through a right rectus incision, surrounded by gross infection. The midabdominal incision through which the original operation had been performed was grossly infected. Peritoneal or retroperitoneal infection was manifested by tenderness in the right lower quadrant and the lower abdomen. No definite abscess was apparent. The long wound in the right thigh involving the adductor muscles was moderately infected. There was a large sacral decubitus. The colostomy wound was clean, but the colostomy was not functioning.

Laboratory studies showed the serum protein to be 5 gm per 100 cc and the hemoglobin 61 per cent, despite moderate

FIGURE 2

died of sepsis eight days later. The third case in this group is illustrative of this type of problem and is of sufficient interest to merit a detailed presentation.

CASE 2 The patient was wounded on July 25, 1944, when a high-explosive shell fragment entered the anterior abdominal wall just to the right of the midline below the umbilicus. He was operated on 6 hours after injury at a field hospital under Pentothal Sodium anesthesia, and was found to have perforating wounds of the ileum and colon. A resection of the ileum, with end-to-end anastomosis, was done. The wound in the sigmoid was repaired with a purse-string suture, and a Mikulicz colostomy was performed proximal to the area of injury. A partial traumatic amputation of the left 5th finger was completed, and a wound of the right thigh was debrided.

The patient did well up to the 11th postoperative day, at which time he was given prostigmine. This was followed by signs of acute intestinal obstruction. On the following day, the abdomen was reopened and obstruction at the site of the anastomosis was found. A double-barreled enterostomy was done at the point of obstruction. Postoperatively the patient did poorly, although there was evidence of relief of the obstruction. He was transferred to this hospital on the fourth day after the second operation.

Physical examination on admission showed an acutely ill, extremely emaciated patient. There was slight jaundice and moderate peripheral edema. There was a double-barreled

dehydration. The patient had received sulfadiazine parenterally up to the time of admission.

Treatment consisted of daily infusions of blood or plasma, penicillin parenterally and frequent dressings to control infection and prevent digestion of the skin around the ileostomy. Although there was an ill-defined inflammatory mass in the right lower quadrant, the presence of the ileostomy, the profound nutritional disturbances and the patient's poor general condition rendered exploratory search too hazardous. The patient seemed improved one day and worse the next, and became progressively more jaundiced.

Despite supportive measures, the patient gradually lost ground, becoming irrational and semicomatose by the 15th hospital day. He showed evidence of nitrogen retention, the highest nonprotein nitrogen level being 84 mg per 100 cc, despite a parenteral fluid intake of 3000 to 4000 cc daily and a urinary output of 1500 to 2000 cc. The wound in the right thigh seemed to be developing a deep cellulitis. It was thought that this was due to retroperitoneal infection extending downward along the fascial planes and that the wound in the thigh might have continuity with the abdominal incision, but although the purulent discharge of the abdominal and thigh wounds was similar, actual continuity was never proved. The increase in drainage from the thigh coincided with an abrupt end of the downward course, and from this point on gradual improvement was noted. The icterus slowly cleared. Eventually further surgical drainage of the thigh was carried out. The spur on the double-barreled colostomy was cut down, and the wound infection cleared.

globin levels had been restored to normal. In the case of deep seated and poorly localized infection, a more conservative policy was adopted. It is well known that the peritoneum has a remarkable natural ability to deal with residual abscesses, accordingly, the patient was placed on the nutritional regime outlined in Table 2. Parenteral penicillin was given in amounts of 30,000 units every two hours, and the course of the disease was carefully observed. If the infection became well localized

removal was followed by a severe hemorrhage, which was finally controlled by packing. The abdomen was closed, the pack being left in the wound.

The patient was transferred to this unit on the 9th post operative day. He had a severe anemia and was profoundly septic, the daily temperature varying between 101 and 104°F. The packs were still in the wound, in which there was considerable deep infection, with marked digestion of the surrounding skin. There was mild jaundice. Examination of the abdomen revealed tenderness and a sense of resistance in the right upper quadrant on deep palpation that suggested a mass.

Initial therapy consisted of multiple plasma and whole blood transfusions, in accordance with the program outlined in Table 3. Removal of the pack in the wound produced no hemorrhage, but drainage became more profuse than ever, and at times appeared to be pure bile. Despite meticulous and frequent dressings, surgical drainage of the wound and the application of suction to the fistulous tract, the wound was slowly undermined by progressive infection. Although there was a gradual rise in the hemoglobin with multiple transfusions, the patient remained profoundly septic, and his general condition was obviously deteriorating.

On August 23, 24 days after the injury and 15 days after admission, the jaundice became intense. The patient refused all food by mouth and became markedly listless and apathetic. Part of this reaction may have been due to the disturbances of acid-base metabolism caused by the high intestinal fistula. Carbon dioxide determination could not be done, but there was no tetany, the urinary output was good, and the hemoglobin and serum protein levels continued to show an upward trend. The possibility that the multiple whole-blood transfusions had produced the jaundice was raised by some observers. The patient had had severe chills and sweats with the marked swings of temperature but none of these had been closely related to a whole-blood transfusion, and there had been no hemoglobinuria. There was bile in the urine. It was reasoned that there was an incompletely drained abscess in the right upper quadrant, that this partially accounted for the jaundice, and that the duodenal fistula would not heal or subside until it was drained. Until the duodenal drainage subsided the wound infection could not be expected to clear up.

Accordingly, on August 26, under local anesthesia, the right upper quadrant was explored through an oblique subcostal incision, the original wound, which was in the midline, being carefully avoided. In the right subhepatic space there was a huge cavity filled with the same type of fluid as that draining from the wound. It was impossible to demonstrate a communication with the original wound, but the exact limit of the cavity could not be felt. All fluid was removed, and the cavity was drained.

Following this operation there was steady improvement. The patient became more alert and resumed eating, and the jaundice began to diminish. It is interesting, however, that the temperature went higher than before, ranging between 101 and 105°F. Since the patient's general condition appeared improved the febrile reaction was disregarded, and at the end of 2 weeks the temperature began to decline. The fistula was diverted from the original badly infected abdominal wound to the oblique subcostal incision, and the original wound rapidly cleared up and healed. By vigorous efforts on the part of the nursing staff, the second wound was kept clean and in good condition despite the excessive amount of drainage, and it gradually healed, leaving only a small fistulous tract. Six weeks after operation the patient was ambulatory and afebrile. The wounds were healed, but there was still a small fistula, which on lipiodol injection was found to enter the second portion of the duodenum. It seemed likely that this would heal without further intervention.

The patient was evacuated in excellent condition. He made steady progress and was ready for return to duty 8 months after injury. The fistula healed spontaneously.

Patients with undrained areas of infection that cannot be readily localized present a still more baffling problem. There were 3 patients in this category, 2 of whom died. One death was due to rapidly progressive peritonitis. The patient had received extensive shell wounds of the left side of

FIGURE 1

and easily accessible through "pointing," as in a pelvic abscess, it was drained. If no localization occurred but there was a gradual and steady improvement in the patient's condition, as evidenced by a rise in the hemoglobin and serum protein levels, a decline in temperature and an improvement in appetite, a conservative policy was continued. In 3 cases, complete resolution of intraperitoneal sepsis occurred under this regime and no surgical intervention was required. If, on the other hand, no improvement occurred or if the patient appeared to be losing ground, operation was carried out regardless of the risk it entailed, provided there was reasonably accurate localization of the infection by clinical signs. The following case report is illustrative.

CASE 6 The patient received a perforating gunshot wound in the right upper quadrant of the abdomen on July 31, 1944. He was operated on 6 hours after injury and was found to have a perforation of the ileum, which was closed by suture. The bullet was felt in the retroperitoneal tissues in the region of the second portion of the duodenum. Its

considered under conservative therapy also made steady, although less dramatic, improvement. In these 12 cases the nutritional regime employed can be described as adequate. In 2 of the remaining 4 cases, convalescence was greatly prolonged by residual, poorly localized infection and by the presence of external intestinal fistulas. Under these circumstances, although anemia and hypoproteinemia were prevented, the patients steadily lost weight on the nutritional regime employed. As soon as infection was eradicated, however, they promptly improved.

Two patients died, one of overwhelming peritonitis shortly after admission and the other of inadequately drained retroperitoneal abscesses, which were not detected until the post-mortem examination. When it is considered that these cases were the most serious ones evacuated at the time from three different field hospitals, the end results may be described as gratifying.

DISCUSSION

In the postoperative care of the patient with war wounds of the abdomen, two cardinal principles should guide the surgeon — maintenance of nutrition and eradication of infection. These are complementary, since the well nourished patient can better resist infection and, conversely, nutrition improves as soon as infection subsides.

In actual practice, the maintenance of nutrition in these patients is difficult. Despite the liberal use of blood and plasma in forward areas, the enormous losses that may accompany extensive abdominal wounds are rarely completely replaced, and the nature of the injury in itself temporarily prohibits the taking of food by mouth. Thus, unless specific corrective measures are taken every patient develops a certain degree of anemia and malnutrition. Fortunately, if a good salt-and-water balance is maintained this period of starvation is readily withstood by the majority of patients, but if complications develop, particularly peritoneal or retroperitoneal infection, external fistulas and intestinal obstruction, the patient faces these additional burdens already seriously handicapped by malnutrition. Once a complication develops, the nutritional state deteriorates at an appalling rate.

It therefore becomes essential to attempt to maintain nutrition from the beginning by some such regime as that outlined in Table 3. The additional blood and plasma are little enough, and by no means satisfy the basic caloric requirement. A perfect parenteral food substitute has not been developed, but whatever substance is available should be employed to the fullest extent. The liberal use of blood and plasma in the early postoperative period is a step in the right direction. The administration of amino acids, — hydrolyzed casein, — either parenterally or in small amounts orally is desirable in the care of certain of these patients. Nutritional regimes

similar to those outlined by Co Tui et al.⁷ and Elman⁸ more closely meet the nutritional demands than does the regime employed in the present study. To the surgeon of the future it will seem as unwise to fail to feed these patients parenterally from the very moment of operation as it now seems to us to fail to transfuse a patient who has had a massive hemorrhage merely because he is likely to survive without transfusion.

The danger of residual infection demands constant vigilance. Adequate drainage of wounds and of local and easily accessible abscesses must be carried out promptly. In the case of deep-seated peritoneal and retroperitoneal infection, the condition of the patient must be weighed in the balance. If he is obviously getting well, the problem may solve itself. The natural ability of the peritoneum to combat residual infection is well known and is confirmed by this study. It is in the patient who is not getting well that an aggressive attitude toward residual infection must be adopted. Subphrenic and pelvic abscesses may be diagnosed with relative ease, and their management is standardized. Foreign bodies should be regarded as a possible clue to the location of obscure infection. If these sources are excluded, it is our conviction that in the failing patient an exploratory search for hidden abscesses is justified. This may indeed appear a drastic measure, and sound judgment must be exercised in appraising the given patient, but by this means certain lives can be saved that would otherwise be lost.

Since the presence of external fistulas adds a serious burden to the patient convalescing from abdominal wounds, open ileostomies should be avoided. Associated infection, however, appears to have a more deleterious effect on the nutrition of a patient than does external fistula alone. If infection can be controlled, a fistula may heal spontaneously. If a patient is losing ground, surgical repair of a fistula should not be delayed.

SUMMARY

A report is presented of the nutritional problems encountered in a series of 16 patients with extensive abdominal wounds. The series was a selected one in that these patients were too ill to be evacuated directly to the United Kingdom during the early weeks of the campaign in Normandy.

The need for an adequate nutritional regime in the early postoperative care of these patients is emphasized. The liberal use of blood and plasma, not only before but for some time after operation, is necessary.

A routine nutritional program is presented. In cases in which residual infection was readily eradicated this program proved adequate. When there was persistent infection, convalescence was prolonged and a parenteral food substitute to increase the total caloric intake would have been desirable.

The patient soon began to take food by mouth, and from this time on his progress was steady. The jaundice cleared entirely, the azotemia subsided, and the blood picture returned nearly to normal. On October 4, an attempt was made to cover the large sacral ulcer with skin. Although the granulations appeared healthy, a split-thickness graft failed to take. On October 18, an attempt was made to close the ileostomy under local anesthesia. No attempt was made to free the bowel because it seemed that the patient's general condition would not withstand an extensive procedure, but the closure broke down 36 hours after operation. Despite the leaking ileostomy he continued to improve, and he was evacuated in fair condition. Subsequent reports indicate that he made a slow but steady recovery.

The management of this type of case remains a problem, but it is our belief that if improvement does not occur under so-called "conservative" management, an operation to find and drain the infection must be undertaken even if it requires an exploratory laparotomy. In this case a more aggressive policy, with drainage of the peritoneal infection and closure of the ileostomy at an early date, might have been wiser. If spontaneous drainage of the retroperitoneal infection had not occurred, the patient would probably not have recovered. In this type of case, in which convalescence is prolonged by deep-seated, poorly localized infection, the maintenance of nutrition is exceedingly difficult. It is comparatively easy to prevent hypoproteinemia and anemia by frequent transfusions of blood and plasma, but despite this fact there is progressive weight loss and wasting of the subcutaneous tissues. Small amounts of highly nutritious liquids may be given by mouth, but at times these are not well tolerated, and even when they are it is difficult to raise the caloric intake above 2500 daily. Under such circumstances the use of protein digests, which were not available, would be desirable.^{7, 8}

EXTERNAL FISTULAS

There were 5 patients with external fistulas, — in the urinary tract in 3 cases, in the duodenum in 1, and in the ileum in 1. The urinary fistulas were relatively innocuous so long as there was adequate external drainage. The 2 patients with intestinal fistulas, whose cases have been presented in detail, presented extremely serious problems. It is significant, however, that once infection was controlled their general condition improved despite the presence of the fistula, and in 1 case the fistula healed spontaneously. The difficulties encountered in the case in which an ileostomy had been performed support the contention of the surgeons who maintain that ileostomies cause more deaths than cures. Also, it is evident that if a patient is losing ground, a surgical attack on the fistula should be undertaken early, before his condition has deteriorated to such a point that even a limited procedure cannot be tolerated.

CHEMOTHERAPY

All these patients had received sulfanilamide in the wound and sulfadiazine and penicillin paren-

terally prior to admission to this hospital. There was considerable variance in the dosages used and, so far as could be determined from the records, some irregularities in the schedule of administration. In general, however, all the patients had received combined therapy in reasonably adequate dosages over periods of seven to sixteen days. On arrival at this hospital the sulfonamides were discontinued. This was done for several reasons. First, it was argued that whatever residual infection these patients showed had developed despite the use of the drugs, and that therefore their continued use was not likely to be beneficial. Second, the probable nature of the infection — namely, a localized collection of undrained pus — made it unlikely that sulfonamide therapy would affect it. Third, the continued use of sulfonamide drugs, with their tendency to produce toxic and febrile reactions, would add an additional factor to cases already so complex that interpretation of the cause of fever was difficult. Finally, and most important, it seemed unwise to continue the use of these drugs in patients with such profound metabolic disturbances — that is, dehydration, anemia, hypoproteinemia, azotemia and jaundice.

The sulfonamide drugs were discontinued because of certain specific objections to their use. Since no such objections were known to pertain to the use of penicillin, and since it seemed unwise to discontinue all chemotherapy, this agent was employed routinely in large amounts — 30,000 units every two hours. We were influenced in this decision by two things. First, the controlled observations of Lyons⁹ indicate that the nutritional status of patients with septic wounds is restored to normal more rapidly when penicillin is given, as well as blood and plasma. Second, our previous experiences with the use of this drug had revealed dramatic improvement after its use in several patients gravely ill with longstanding abdominal sepsis.

Since penicillin was used routinely without control periods of observation, there are no data on which to base an appraisal of its value. Although it was given in large amounts over a period of many days and weeks, — one patient received 4,000,000 units, — no toxic reaction was observed. The repeated hypodermic injections became an ordeal for some patients, particularly those whose convalescence was prolonged. It is our impression, based only on a comparison between the course of these cases and our recollection of the course of similar cases treated without penicillin, that the drug was of value.

RESULTS

The nutritional state of 9 of the 16 patients rapidly improved under the regime outlined in Table 2. These were the patients in whom sepsis was promptly eradicated by adequate drainage. Three patients in whom residual peritoneal infection sub-

blood pressure of the upper extremities of dogs in which experimental coarctation was induced by means of Goldblatt clamps applied to the aorta. He attributes this phenomenon to the prompt and ready development of collateral channels in these animals.

King¹⁰ has pointed out that with embarrassment of circulatory compensation the blood pressure may drop to normal levels, and he has in addition reported a case in which a normal tension in the brachial arteries was found in an asymptomatic woman, in whom he postulated the existence of an aortic coarctation. The patient presented physical evidences of collateral circulation and a blood pressure lower in the popliteal arteries than in the brachials, with dilatation of the ascending aorta the only striking radiologic feature.

Failure to palpate both radial pulsations simultaneously or to determine blood pressure as a routine in the right arm, when only unilateral readings are taken, obscures the presence of a hypertension or pulse asymmetry in cases in which the pathologic process extends to or above the origin of the left subclavian artery.^{11,12} That the right arm rather than the left should be chosen for routine unilateral blood pressure determinations is a point that has been insufficiently stressed. King¹⁰ has emphasized the work of Korms and Guinard and of Stueglitz and Propst, who have pointed out that in most persons the blood pressure in the right arm is usually higher than that in the left. The reasons given for this difference have been many, but the difference in the anatomy of the blood supply to the right and the left upper extremity is probably the most important single factor.

As pointed out by Gitlow and Sommer,¹³ in cases in which the collateral circulation is well established and constant, no difference in pulse volume and blood pressure between the upper and lower extremities may be detectable by ordinary clinical means. One of the patients of Stewart and Bailey¹⁴ showed no reduction in the blood pressure of the legs as compared with that of the arms.

The third diagnostic criterion — namely, the presence of a loud systolic murmur over the manubrium and in the left interscapular space — is of importance only in indicating the need for an extension of the search for its etiology. Nothing is pathognomonic about the murmur, since its character varies in different cases.

Pulsation of the subscapular, intercostal and internal mammary arteries, interpreted as evidence of marked development of collateral circulation, is considered one of the most valuable clues to the diagnosis of coarctation of the aorta. Although such conditions as aneurysm, intrathoracic neoplasm and certain types of exophthalmic goiter may, as pointed out by Blackford,² produce a similar finding the possibility of confusion is not great. Indeed, King¹⁰ believes that the evidence of collateral arterial

circulation is the most important single clue to the diagnosis, this sign having been present in all the 16 cases of coarctation that he has examined. In Blackford's series, collateral circulation was clinically detectable in 35 cases, was not mentioned in 15 cases, although it was implied in about half of these, and was absent in 5 cases. In one of the cases reviewed, the patient, a pilot, who while living presented no clinical evidence of superficial collateral circulation, was revealed at post mortem to have had dilated internal mammary vessels serving as the principal site of the necessary shunt.

It is apparent that the clinical detection of evidences of collateral circulation depends in great degree on which of two main routes of blood flow is utilized.¹⁵ If there is anastomosis of the branches of the subclavian artery, such as the superior intercostal, postscapular, interscapular and subscapular arteries, together with the aortic branches of the internal mammary arteries, with the first four intercostal arteries, most of the blood thus being carried into the descending aorta and thence to the lower extremities, the evidences of collateral circulation may well be marked. If, however, a more circuitous but less superficial anastomosis — that of the internal mammary arteries with the superior and inferior epigastric arteries — occurs, clinical evidence of collateral circulation may not be so obvious. It is in the latter instance especially that a useful diagnostic procedure — namely, simultaneous palpation of the right radial and femoral pulses — is a valuable adjunct, in that a distinct lag in the summit of the femoral pulse may be felt. As a corollary, it can be stated that a diminished or absent femoral pulse¹⁵ was noted in many of the cases reported.

The latter finding unfortunately has assumed undue prominence in the diagnostic armamentarium of many clinicians, and it is with this phase of the subject that the present paper is primarily concerned. It has been our experience that many physicians in examining cases in which coarctation of the aorta must be considered in the differential diagnosis have ruled out its presence on finding normal femoral pulsations, or pulsations in the more peripheral arteries of the lower extremities. This misconception has crept into the literature. In Musser's¹⁶ textbook it is stated, "The blood pressure reading from the arms is usually elevated, whereas the pulsation in the femoral arteries is greatly reduced or may even be imperceptible." In a recent article, Baker¹⁷ states that a cardinal sign of coarctation of the aorta is absence of pulsations in the peripheral arteries of the lower extremities. "If a feeble pulsation is detected over the femorals," he continues, "it is asynchronous with the radial pulse. If the pulsations of the dorsalis pedis and posterior tibial arteries are present, coarctation can be excluded as a possibility without further ado." In a paper by Green¹⁸ it is stated to be the practice to palpate routinely for pulsations in the femoral arteries. If

The management of residual or latent infection is an essential feature of any nutritional program. Adequate drainage of wounds and of localized abscesses must be promptly performed. A persistent search for undrained foci of infection must be carried out, and on occasion in the failing patient an exploratory operation is justified.

Since external fistulas add a serious burden to the patient with abdominal wounds, open ileostomies should be avoided. Associated infection, however, appears to have a more deleterious effect on the nutrition of a patient than does an external fistula

alone. If infection can be controlled, a fistula may heal spontaneously.

COARCTATION OF THE AORTA*

A Report of Two Cases

MAJOR ROBERT FRIEDENBERG, M C, A U S, AND CAPTAIN ARCHER J. SOKOL, M C, A U S

SINCE the first case of coarctation of the aorta was recorded in 1791, many excellent papers concerning the nature of this interesting condition have been published. Both the infantile and adult forms, with their pathogenesis, anatomy, associated diseases, such as cerebral and other types of aneurysms, symptomatology and diagnostic and constitutional characteristics have already been ably and exhaustively reviewed.¹⁻⁵ Indeed, Lewis⁴ states, "So much has been written about coarctation of the aorta that new records of cases can have little value unless they reveal new features of interest or importance to the study of the condition." This statement might well dissuade one from writing another paper on the subject, were it not for the need of calling attention to some of the uncritical diagnostic procedures that have won general usage. For example, many physicians, with a false sense of assurance, rule out the presence of coarctation of the aorta by the finding of a normal femoral pulse. A review of the literature and study of the 2 cases presented in this paper indicate that diminution or absence of the femoral pulsation in aortic coarctation is one of the less constant signs.

According to Pardee,⁶ the major criteria in this anomaly are four in number. They are as follows: erosions of the margins of the ribs, absence of the aortic knob and dilatation of the ascending aorta, a high blood pressure limited to the upper extremities, a loud systolic murmur audible over the manubrium sterni and in the left interscapular area, and pulsations of the subscapular, intercostal and internal mammary arteries.

Even a cursory review of the literature reveals that almost any of these features may be absent or

obscure in a given case. Thus, absence of rib crenations, especially in younger patients, is not unusual. Lack of prominence rather than absence of the aortic knob in the radiographic silhouette is frequently seen in coarctation of the aorta as well as in other types of cardiac disease. In left-oblique films, the retroaortic and retrocardiac spaces are said to be clear in cases of coarctation,⁷ instead of presenting the normal haziness in this area ordinarily produced by the ascending arch and the upper portions of the descending thoracic aorta. These findings may, however, be obscured, since young persons may normally show minimal density of the aortic shadow.

Left-ventricular hypertrophy is not a regular finding, and its presence in so many other cardiovascular diseases limits its value as a pathognomonic sign in this one.

Dilatation of the ascending aorta seems to be the most constant radiologic feature, excluding, of course, angiocardigraphic studies, which at present are not in widespread use. Syphilitic aortitis may produce a similar picture, but the differentiation should not prove difficult. Thus, it is seen that in ordinary radiographic or fluoroscopic examination the combination of dilatation of the ascending aorta and lack of prominence of the aortic knob is the most frequently demonstrable finding.

A high blood pressure limited to the upper extremities is one of the most constant features of the disease. The reason for the hypertension has not been unequivocally demonstrated. The theory most favored postulates an increased peripheral resistance by the coarctation and the collateral circulation as the main cause.⁸ Page,⁹ however, has been unable to demonstrate a consistent rise in the

Posteriorly systolic bruits were heard over the left chest. No visible palpable arterial pulsations were noted posteriorly.

Fluoroscopic examination in the posteroanterior position revealed elongation and rounding of the left lower ventricular contour, with an undulating type of pulsation at the waist of the heart. The ascending aorta was broadened, pulsations were moderately exaggerated, and the aortic knob was not so prominent as it normally is. In the right anterior oblique position, there was moderate encroachment on the retrosternal space. The width of the aorta at its uppermost margin seemed normal. In the left anterior oblique position, there was a markedly expansile type of pulsation in the region of the mid lower tract of the left ventricle. The contour of this portion of the left ventricle seemed more convex than that normally seen. The ascending aorta appeared broader and more anterior in position than normal. The aorta could not be traced under the arch. X-ray examination of the chest revealed areas of cretation along the lower borders of several of the ribs. The diagnosis was coarctation of the aorta, with an enlarged heart.

The electrocardiogram revealed a rate of 78, with a sinus rhythm. A small Q₁ and inverted T₃ were present. There was a tendency to left-axis shift.

The patient in Case 1, aside from presenting what was suggestive of a subsiding infectious mononucleosis, was admitted with a dispensary diagnosis of pleurisy. Analysis of his symptoms showed that the chest pain was undoubtedly related to coarctation of the aorta. The pain was in all probability due to root or nerve pressure caused by passage of the enlarged anastomotic arteries through the intervertebral foramina.^{2,3} The patient sustained an injury of the left foot and leg from a hand grenade, and ten hours later operation was performed for arterial repair in the left thigh and repair of an artery above and posterior to the ankle. According to the patient, recurrence of bleeding at the site of the arterial repair in the thigh ten days later necessitated reoperation. This injury may explain the absence of the dorsalis pedis and posterior tibial pulsations in the left foot contrasted with the right.

Case 2 is that of an asymptomatic medical student who had previously been repeatedly examined during participation in the Army Specialized Training Program. Hypertension, which was brought down to the upper limits of normally accepted standards by rest, was known to be present. Apparently the absence of visible and palpable evidences of collateral circulation, as well as the presence of a normal femoral pulse, had previously diverted the minds of the examiners from the possibility of aortic coarctation.

The autopsy incidence of coarctation of the aorta is said to be 1/1550.³ To increase the accuracy of an intra-vitam diagnosis, primary stress must be placed on the most constant diagnostic features, as a preliminary screening measure in ruling out the presence of aortic coarctation. That there is no one clinically detectable and universally constant feature that is easily demonstrable in the course of a routine examination has been shown. Even the almost universal finding of a blood pressure higher in the upper extremities than in the lower was absent in one of the cases reported by Stewart and Bailey.¹⁴ Except, however, for angiocardigraphic studies

such as those made by Grishman et al.,¹² which do not lend themselves to widespread usage, this decrement in arterial pressure in the legs as compared with that in the upper extremities seems to us, as well as to Stewart and Bailey,¹⁴ the most frequent and readily detectable distinctive feature of coarctation of the aorta. The determination of the blood pressure in the lower extremities, although possibly irksome to the busy practitioner, must be made in every case in which otherwise unexplained factors exist, such as bizarre types of murmurs or bruits heard anywhere in the chest, arterial hypertension or prominent or unusual arterial pulsations, regardless of the age of the patient.

At present, the value of prompt diagnosis, aside from the desire for scientific accuracy, lies in the advantage of guiding patients intelligently in forming patterns of activity and hygiene within the limits of their vasculature. Possibly, the future holds promise for more active surgical therapy.²⁴

SUMMARY

The major criteria for the diagnosis of coarctation of the aorta are reviewed and evaluated, and 2 cases are described.

A brachial blood pressure higher than the popliteal blood pressure is one of the most constant and easily detectable clinical features of the disease.

Delayed, diminished or absent femoral pulsation may be noted in many cases but this sign cannot be relied on routinely to rule out coarctation of the aorta.

Determination of the blood pressure in the lower extremities must be made in every case in which otherwise unexplained factors exist, regardless of the age of the patient.

these are absent, the blood pressures are taken. Others^{19, 20} have also recommended palpation for femoral pulses as a necessary procedure. This practice is in conflict not only with our experience but also with that of others. Thus, Stewart and Bailey¹⁴ discovered in their series of cases that the absence of pulsations in the arteries of the legs was an inconstant finding, not only in the femoral vessels but in the popliteal and dorsalis pedis as well.

Certainly, a sign more constant than pulse changes in the lower extremities should be relied on in routinely ruling out coarctation of the aorta. Many other writers have called attention to the basic inadequacies of femoral palpation as an absolute diagnostic criterion. Abbott¹ in her encyclopedic review points out that retardation and diminution or even absence of the femoral pulse is not constant, either in its presence or in the extent of diminution. Blumgart, Lawrence and Ernstene⁸ have made a similar statement. One of their patients showed pulse waves in the femoral arteries approximately equal to those in the radials, and the radial pulse wave appeared approximately 0.05 seconds before the femoral. Differences of this small degree are not detectable by the usual gross clinical methods of palpation. Furthermore, in the case cited the popliteal and dorsalis pedis pulsations were perceptible but weak, although the posterior tibial pulses were not felt. Considering the facts that the patient was sixty-six years old and that auricular fibrillation was present as well, it becomes evident that overattention to the pulse in the lower extremities without due regard to the other more significant signs may cause one to miss the diagnosis. In pulse tracings taken by Railsbach and Dock²¹ in a case of coarctation of the aorta, the femoral arterial pulse followed the radial by 0.02 seconds, a time lag certainly within the limits of subjective error of the observer.

In short, we agree with such writers as Goodson²² that a retarded, diminished or absent pulse in the lower extremities in the presence of a full, bounding pulse in the upper extremities is pathognomonic of coarctation of the aorta provided embolism in the iliac arteries is ruled out. But this statement is accepted in the sense that this finding is pathognomonic only when present, and that coarctation not infrequently exists in its absence.

There follow the reports of 2 cases in which the femoral pulsations were easily palpable and of normal volume, with nothing in the nature of the pulsations that was considered as diagnostically significant.

CASE REPORTS

CASE 1 The patient, a 25-year-old German prisoner of war, entered a station hospital on June 28, 1944, complaining of sore throat and pain in the left side of the back over the lower ribs of 10 days' duration. He was a well developed and well nourished, broad-shouldered and narrow-waisted man of athletic build. There had been no unusual childhood

diseases. The patient had experienced some dyspnea on moderately severe exertion for the last 3 years, especially when swimming. For the last few years he had noted pains in the left side whenever he engaged in unusually strenuous work or exercise. The pains were stabbing, were aggravated by movement and by bending and usually disappeared spontaneously after 5 or 10 minutes' rest. On January 30, 1944, this patient's left foot and leg were injured by the explosion of a hand grenade. He was operated on 10 hours after injury for repair of the posterior tibial artery (?) of the left leg and also for arterial repair in the medial aspect of the left thigh above the knee. Because of recurrence of bleeding a second operation was performed 10 days later.

Early in the following June, the patient was sent to pick onions on a farm, and shortly thereafter the pain in the back became more constant, with fewer intervals of freedom from pain. It was especially aggravated by bending forward. It was localized over the left lower ribs and was neither severe nor completely disabling.

Physical examination revealed traumatic and operative scars at the medial aspect of the lower third of the left thigh and the lower third of the left leg over the posterolateral area. The pharynx was slightly injected. Forceful carotid pulsations were noted in the neck, and a systolic bruit was present. Systolic bruits were heard best over both infrascapular fossas and at the level of the 3rd rib posteriorly in the inter scapular area. There was a visible pulsatile and palpable artery, somewhat tortuous in its course, over the medial and upper border of the right scapula. An occasional sibilant rale was heard posteriorly. Vascular examination revealed a posterior tibial artery pulse barely palpable on the right and nonpalpable on the left, and a dorsalis pedis pulse weakly palpable on the right and absent on the left. The femoral pulses were easily palpable and of normal volume bilaterally. The radial vessels were somewhat thickened in relation to the patient's chronologic age. The blood pressure was 180/100 in both arms and 120/100 in both legs.

Cardiac examination revealed visible arterial pulsations over the left anterior axillary area. There was accentuation of the aortic second sound, with palpable closure of the aortic valve and a blowing systolic aortic murmur. A musical systolic murmur, moderate in duration, was heard at the apical region and was transmitted to the left anterior axillary region, and also to the right toward the xiphoid process and along the left sternal border. The rhythm was regular, and there was no displacement of the apex or increased manubrial dullness. The spleen was palpable, firm and nontender and was felt 1 fingerbreadth below the left costal margin. Pulsations of the abdominal aorta were not felt.

The red-cell count was 4,370,000, and the hemoglobin 13.5 gm. The white-cell count was 5400, with 55 per cent neutrophils, 33 per cent lymphocytes, 9 per cent monocytes, 2 per cent eosinophils and 1 per cent basophils. Urinalysis, Kahn test and a blood smear for malarial organisms were negative. The sedimentation rate was 11 mm in 60 minutes. The heterophil antibody test revealed agglutination in a dilution of 1:12.

X-ray examination of the chest in different projections revealed widening of the base of the heart and the ascending portion of the aortic shadow. Fluoroscopic examination showed a strong impulse on the right side of the cardiac shadow and absence of a true aortic arch. Irregular crenation defects were present along the inferior margins of many of the ribs posteriorly. The bronchovascular markings were prominent, but the pulmonary structures were essentially normal. The findings described were compatible with a coarctation of the aorta. The electrocardiogram revealed a normal axis with small Q waves in Leads 1 and 2, a large Q wave in CF, and a diphasic T.

CASE 2 The patient, a well developed, 22-year-old medical student, had known of the existence of hypertension for some time. Previous examinations had always revealed an initial elevated tension, which was brought down to almost normal limits by rest. The past history was noncontributory.

The blood pressure was 174/100 in the right arm and 180/100 in the left in the supine position. Femoral pulsations were readily palpable and of normal amplitude. The blood pressure in the right leg was 120/95. In the supine position there was a blowing systolic bruit, heard best over the xiphoid and transmitted to the left. There was also a blowing systolic and pulmonic murmur of moderate duration and intensity. In the erect position there was heard an impure first apical sound.

TABLE 1 Data in Patients with Known Precursors to Diabetes

CASE No.	AGE yr	RELATIVES WITH DIABETES	HEIGHT	NORMAL WEIGHT lb	DATE OF ONSET	DATE OF HOSPITALIZATION	REGIME ON DISCHARGE	HISTORY OF ONSET
1	22	0	5 ft 5 in	180	Apr 1944	Oct 1944	C200-P80-F80 PZI 15 units RI 10 units	Gradual onset in England of polyuria, polydipsia and polyphagia with 40 pounds weight loss

PSYCHOGENIC FACTORS IN THE ETIOLOGY OF DIABETES

MAJOR B R GENDEL, M C, A U S, * AND COLONEL JULIEN E BENJAMIN, M C, A U S †

EVER since the demonstration by Von Mering and Minkowski that extirpation of the pancreas in dogs produces diabetes, a great deal of research work has been performed to elucidate the pathogenesis of this disease. The influence of heredity has been stressed, and the evidence that diabetes is inherited as a Mendelian recessive has been presented by Pincus and White.¹ Additional factors, such as obesity, have also been evaluated. From the experimental field, the relation of diabetes to the pituitary gland has been demonstrated by Houssay² and that to the adrenal glands by Long and Lukens.³ Recently, the study of experimentally induced alloxan diabetes⁴ has opened new possibilities for research. Fundamentally, however, the factors that operate to precipitate diabetes are not clear, nor is the mechanism whereby these factors operate.

Transient glycosurias following emotional disturbances have been described. Boehm and Hoffmann⁵ produced glycosuria in cats following the arousal of rage and the application of painful stimuli. Cannon, Shohl and Wright⁶ reproduced these experiments without the use of painful stimuli. Folin, Denis and Smilie⁷ reported that 18 per cent of 34 second-year medical students and 17 per cent of 36 female college students showed traces of sugar in the urine immediately following an examination. Glycosuria produced in this manner has been called "emotional glycosuria." It has not been shown to become permanent, nor has diabetes ever been produced experimentally in this manner.

A review of the literature concerning the possibility of producing diabetes by psychic trauma reveals some interesting differences of opinion. Clinicians with great experience in treating diabetics, such as Joslin,⁸ Root⁹ and Von Noorden,¹⁰ are not convinced that such a relation of cause and effect exists. Joslin cites Von Noorden's experience in World War I to the effect that neurogenic diabetes does not occur. As a consultant for a hospital center in France through which 40,000 soldiers passed, Joslin discovered only 2 cases of diabetes, despite his known interest in this particular disease. Matz¹¹

studied diabetes in veterans of World War I, and came to the conclusion that neurogenic factors are of no importance in the etiology of diabetes.

On the other hand, investigators in the psychiatric field, particularly Menninger¹² and Daniels,¹³ are not so convinced that the subject is closed. They believe not only that there is a correlation between mental stress and strain and increases in the severity of the diabetic state but that diabetes may be initiated by psychologic or emotional disturbances. Our interest in this phase of the problem arose after observing several patients in whom a psychogenic trauma seemed to precede the development of diabetes in such a way as to suggest cause and effect.

The records of all patients who were treated for diabetes on the Medical Service of the Lovell General Hospital between August 1, 1944, and June 30, 1945, — a total of 44 cases in 21,993 admissions, — were reviewed. All these patients were seen personally by us.

The diagnosis of diabetes mellitus in these patients was based on either one of two criteria. The first of these was the occurrence of an illness characterized by hyperglycemia — with a blood-sugar level of 300 mg per 100 cc or more — associated with glycosuria and occasionally with acetonuria, and necessitating a diet and moderate to large doses of insulin — 30 or more units daily — for complete control. Some of the patients had had glucose-tolerance tests done overseas and typical diabetic curves had been obtained. In others, no such test had been made, but when an attempt was made to reduce the dosage of insulin, glycosuria and hypercemia appeared, although the patient was on a strict diet and was taking 30 or more units of insulin a day. It was not considered either necessary or desirable to perform a glucose-tolerance test in these cases. The second criterion was as follows. In mild cases of glycosuria, glucose-tolerance tests were done, and in many cases these were repeated after the patients had been on a high-carbohydrate diet for about a week, especially if there was any doubt about the original diet. The diagnosis of diabetes mellitus was made if the blood-sugar value in the test exceeded 180 mg per 100 cc at its peak and did not return to normal within two hours. In

*Formerly, clinical instructor in medicine, Yale University School of Medicine.

†Associate professor of medicine, University of Cincinnati School of Medicine (on leave of absence).

1 case (Case 11), the diagnosis was doubtful. This patient had a definite compensated cirrhosis of the liver and a diabetic glucose-tolerance curve. We could not be certain that the disturbance in carbohydrate metabolism was not solely related to the underlying hepatic disease, but despite this fact the case was included in the series.

It was decided to classify the patients in two groups, comprising those with known precursors to diabetes and those with no known precursors. Inclusion in the former group was based on the factors of a family history of diabetes, of overweight and of age. The family history, which was gone into in great detail, was considered positive when a history of diabetes in the blood relatives, living or dead, was ascertained. An arbitrary 10 per cent increase in weight over that given in the height and weight table of the Association of Life Insurance Directors and Actuarial Society of America¹⁴ was allowed. It was decided to include all patients over forty years of age in this group, because it was thought that these patients had reached the age when the incidence of diabetes increases. All but 2 of these patients were overweight.

The average age of the patients was thirty years, and the ages ranged from nineteen to fifty-four. Forty-three patients were men, and 1 was a twenty-four-year-old nurse. All the patients were white. Two were Jews, in neither of these did the diabetes begin after entry into the Service. In both cases, the diagnosis of diabetes had been made in civilian life, but the patients had been inducted into the Army. They were asymptomatic for two and a half and three years, respectively, at the end of which times the diabetes was rediscovered.

Two possible mechanisms suggest themselves by which psychogenic influences become capable of initiating diabetes. One of these is a functional neuroendocrine disturbance that gradually results in the development of diabetes. One would naturally expect that if this disturbance could be removed, the diabetic state would disappear or greatly improve, but no definite evidence of this sequence was seen. In many cases the diabetic state seemed to improve, but there was no certainty that this was not related to the better regulation of the diet that was possible in the Zone of Interior. The other mechanism is analogous to a trigger mechanism whereby the psychogenic factors initiate the diabetes and the condition, once it has begun, becomes permanent and irrevocable.

Menninger¹² sets down five requirements to which psychogenically induced diabetes should conform. These are an obvious psychopathic state evidenced prior to the development of the diabetic state, a mental picture quite different from the toxic state occasionally seen in hyperglycemia or hypoglycemia, a course of improvement in the mental picture paralleled by the glycemic and glycosuria levels,

with fluctuations of these as emotional upsets occur in the psychic life, indication of the metabolic disorder by a persistent glycosuria, — without dietary control or insulin, — retarded glucose-utilization curves of the blood sugar and a response to dietary and in some cases insulin therapy, and clearing of the diabetes on mental recovery, without the necessity of insulin or rigid dietary treatment.

Complete psychiatric appraisals were not possible in these patients, but they assuredly suffered no marked psychiatric disturbance during their stay at this hospital. Nevertheless, they continued to take insulin, although the amount could be decreased. This decrease could also be explained on the basis of better regulation of the diet. There was no convincing evidence that the diabetes improved on the patients' return to the security of this country, and consequently it is not believed that these cases conform to the criteria set down by Menninger.

In addition, although we are well aware of the dangers of attempting to draw conclusions concerning the incidence of diabetes based on our statistics, we believe that diabetes is no more frequent in the Army than it is in civilian life. This is significant, since a soldier's life involves every kind of psychogenic trauma, including anxiety, insecurity and fear of death, so that a consequent increase in the incidence of diabetes is to be expected. On the other hand, a study of the history prior to the onset of the condition impresses one with the fact that in some of these cases an upsetting incident preceded the development of diabetes. As listed in Table 1, this was noted in 2 patients (Cases 9 and 12). In both these patients there was a family history of diabetes. Among the patients in whom there were no known precursors (Table 2), some (Cases 29, 30, 31, 32 and 34) showed suggestive relations, whereas in others (Cases 36, 37 and 40), the relations were less clear. It is significant that none of these patients recovered a normal sugar metabolism after being released from the stress of combat and realizing that they would soon be separated from the military service by a medical discharge. Follow-up information obtained in 11 patients (Cases 5, 6, 8, 10, 14, 27, 28, 29, 30, 36 and 37) four to six months after their return to civilian life revealed no appreciable change in their diabetic status.

SUMMARY

A study was made of psychogenic factors preceding the onset of diabetes mellitus in 44 patients who were admitted to an army general hospital.

In no case was it possible to prove a direct causal relation between the stress incident to military service and the subsequent development of permanent diabetes.

TABLE 2 Data in Patients with No Known Precursors to Diabetes

CASE No	AGE yr	RELATIVES WITH DIABETES	HEIGHT	NORMAL WEIGHT lb	DATE OF ONSET	DATE OF HOSPITALIZATION	REGIME ON DISCHARGE	HISTORY OF ONSET
26	25	0	6 ft	188	Oct., 1944	Nov. 1944	C233-P110-F105 PZI 30 units RI 10 units	Gradual onset of polyuria, polydipsia, polyphagia and weight loss while overseas

44	24	0	5 ft.	104	July 1944	July 1944	Regular diet	Routine urine examination revealed sugar while overseas

by orchidectomy alone. Although 65 were improved clinically, 10 received no benefit whatever. Hamm³ reported 5 cases all of which were helped by orchidectomy alone. These figures give an immediate improvement in 80 per cent of patients treated by orchidectomy alone.

There are those who favor estrogen therapy rather than orchidectomy. Kearns⁹ treated 37 patients with stilbestrol, with improvement in 30. Kahle et al.¹⁰ reported 7 patients benefited by stilbestrol alone, and of 12 patients so treated by Marquart and Flaherty,⁶ 5 were improved. A case of spinal-fluid block relieved by stilbestrol alone was reported by Clarke and Viets.¹¹ Since approximately 75 per cent of patients treated with estrogens alone were improved, there appears to be little to choose between castration and estrogen therapy. Most writers believe, however, that the most spectacular and quickest beneficial results are obtained by orchidectomy. The issue is further confused by the fact that many authors have employed both castration and estrogenic therapy together.¹² It is obvious that more time must elapse before it becomes clear which form of treatment is the better.

Any hope that cancer of the prostate might be cured by endocrine therapy was dissipated long ago. All observers agree that the effects of such treatment are temporary and that sooner or later androgens from some source in the body again stimulate the cancer cells to activity. Regression of the primary growth and of metastatic lesions may be prompt and striking, and an almost unbelievable change for the better in the patient's physical condition may take place, but after months or a few years symptoms can be expected to reappear and the growth to become active again. It has been thought that the lesions that more closely resemble the adult gland respond best to treatment,¹³ but others have found no correlation between the grade of malignancy and the length of relief afforded by treatment, and believe that lesions of higher grades of malignancy respond as well as, if not better than, those of lower grades.¹⁴

The expectation of life for those with cancer of the prostate, before orchidectomy or estrogen therapy was employed, was estimated by Bumpus¹⁵ in 1926 from a study of 1000 cases at the Mayo Clinic. The average survival period was thirty-one months after diagnosis. Two thirds of those with metastases were dead nine months after their first treatment, and 58 per cent of those without metastases were dead in one year. In 1937, Welch and Nathanson¹⁶ studied 204 cases of cancer of the prostate for life expectancy and reported that of 39 untreated patients, 25 per cent were dead in eight months, 50 per cent in twelve months and 75 per cent in twenty-one months after the onset of symptoms. Of the 175 treated patients, 25 per cent were dead in fifteen months, 50 per cent in twenty-six months and 75 per cent in forty-one months. They state

that the British Ministry of Health found the average duration of life in 30 untreated cancers of the prostate to be less than seventeen months after the onset of symptoms.

The improvement in life expectancy that has resulted from the newer methods of treatment is shown by the following figures. Seventy-five patients with prostatic carcinoma treated by orchidectomy and carefully followed were reported by Nesbit and Cummings⁷ in 1944. One third had died and two thirds were alive twenty-one months after operation. Eighty-four per cent of the patients with metastases passed the nine-month period in which Bumpus¹⁵ reported a survival rate of only 33 per cent. Eighty-seven per cent of the patients without metastases were alive after twenty-one months, as contrasted with a survival rate of only 42 per cent after one year in Bumpus's series. When compared with Welch and Nathanson's figures of 50 per cent of treated patients alive after twenty-six months, the 66 per cent of total patients treated by Nesbit and Cummings by orchidectomy and alive after twenty-one months is less striking. The average duration of life of 21 patients with metastases who died after castration was only 11.3 months, although many of them were doubtless in an advanced stage of their disease. From the Mayo Clinic, Emmett and Greene¹⁴ reported that 66 per cent of 133 patients were living eighteen months after orchidectomy and that 78 per cent of those with metastases survived the nine-month period. This again shows an improvement over Bumpus's figures, but the fact that 44 per cent of the patients were dead within eighteen months is not so impressive when compared with the 50 per cent of treated patients dead in twenty-six months as reported by Welch and Nathanson before androgen control. There seems little doubt that endocrine therapy prolongs the lives of patients with cancer of the prostate, but it is not yet clear just how much can be expected in this direction, particularly when the natural course of the disease varies so greatly.

The question of when endocrine therapy should be instituted is still being debated. A questionnaire was sent to seventy urologists in an effort to settle this point.¹⁷ The answers were revealing in showing the confusion that exists concerning when treatment should be begun. One third of the urologists questioned perform bilateral orchidectomy as soon as the diagnosis of cancer of the prostate is made. Most of the rest delay it until metastasis can be recognized by x-ray, symptoms or laboratory evidence. A few do not favor the operation. From their observations, Nesbit and Cummings⁷ conclude that the maximum benefit to the patient is derived by delaying endocrine treatment until the onset of symptoms from advanced or metastatic lesions has occurred. Others^{12, 18, 19} agree with this.

There appears to be no definite evidence that castration or estrogen therapy prevents metastases.

MEDICAL PROGRESS

UROLOGY

Carcinoma of the Prostate

FLETCHER H. COLBY, M.D.*

BOSTON

THE beneficial effects of a reduction of the male sex hormone (androgen control) in patients with carcinoma of the prostate were strikingly demonstrated by Huggins and Hodges¹ over four years ago. Since that time, a great many reports of the effects of castration and estrogen therapy on the malignant prostate have appeared. Although there is still no uniform opinion on the best method of treating this disease, there is a tendency toward agreement on certain points.

A wave of enthusiasm for castration in all cases of prostatic cancer followed these earlier reports. This was tempered by a few skeptics. On the other hand, castration and estrogen therapy have obviously been more effective in their immediate beneficial results than has any other treatment previously employed. The use of external or interstitial radiation has greatly decreased, and the partial removal of obstructing tissue by perineal operation has been largely abandoned in the treatment of prostatic cancer. From the many reports published during the last few years on series of cases of prostatic carcinoma treated in various ways, the questions arise whether castration or estrogen therapy is the better procedure, how effective and how permanent these methods are, and when these measures should be instituted.

There is fairly general agreement that the radical operation of Young, consisting of total perineal removal of the carcinomatous gland, including the capsule, prostatic urethra, bladder neck and seminal vesicles, is the only method that offers any expectation of cure. Objections to this procedure have emanated from those who believe that lymphatic extension has already taken place in practically every case of prostatic cancer when first seen, and

from those who point out that few patients present themselves early enough to make this operation practical. It is true that the cancer should not have spread beyond the prostatic capsule, or at the most should involve only the lower ends of the seminal vesicles, if the radical operation is to be undertaken. If the results of radical surgery are good, however, it would seem that the patients who are found suitable for it, no matter how few, should not be denied its advantages. From the Brady Urological Clinic at the Johns Hopkins Hospital, Colston² reported that 23 per cent of the patients admitted to that institution with carcinoma of the prostate were subjected to radical operation. Probably less than 5 per cent of similar patients seen in most other clinics are found suitable for this operation. Previous reports from the same source have emphasized the value of radical surgery in early cancer of the prostate and bear sufficient evidence of long-term apparent cure to justify its use. According to Nathanson,³ the following percentages of five-year cures of early cases of prostatic cancer treated by radical perineal prostatectomy have been reported: Belt, 58 per cent, Young, 53 per cent, and Colston, 50 per cent. Such figures appear to refute those who hold an entirely pessimistic attitude toward any possibility of cure of prostatic malignant disease.

It is also generally agreed that the majority of patients with cancer of the prostate are immediately benefited by castration or estrogen therapy. Bumpus et al.⁴ recently reported 25 cases treated by orchidectomy, with improvement in all but 1. Huggins et al.⁵ treated 21 cases by orchidectomy, with improvement in 15. Of 21 cases similarly treated by Marquart and Flaherty,⁶ 11 were improved. Nesbit and Cummings⁷ treated 75 patients.

*Instructor in surgery, Harvard Medical School; chief of the Urological Service, Massachusetts General Hospital.

arrest the disease. In younger women in whom it is desirable to preserve ovarian tissue, localized excision of involved areas is advised. In women near the menopause, roentgen-ray irradiation of the ovaries usually causes the bladder lesions to disappear. If the lesions persist or progress after the removal of all ovarian tissue, segmental resection of the bladder wall is necessary.

RENAL CALCULI

Three years ago, a new technic for the operative removal of small stones in the kidney was described by Dees.²⁵ Since the recurrence of stones after pyelolithotomy is frequent and is due in many cases to failure to remove all small calculi at the time of operation, a method that helps to clear the kidney completely is of considerable importance. Dees's contribution may be regarded as a significant advance in the problem of renal calculi.

Following a prolonged, traumatic and apparently futile exploration of a kidney for a small elusive stone, as described by Dees, a blood clot was removed from the renal pelvis, within which the small calculus was entrapped. Impressed by this fortunate accident, he searched for a suitable coagulum to fill the renal pelvis and calices. Fibrinogen from human plasma fulfilled the requirements of a substance that would completely fill the interior of the kidney, clot quickly and firmly, not be harmful to the kidney and dissolve spontaneously. Fibrinogen solution is converted into a fibrin clot by adding thrombin. The thrombin used is a fraction of globulin derived from rabbit plasma. The coagulum formed is said to dissolve spontaneously in human urine at 37°C within eighteen to twenty-four hours. At operation the upper ureter and renal pelvis are exposed. The ureter is gently occluded and a small incision is made in the renal pelvis. A No. 12 French urethral catheter is put into the pelvis, and any urine present is aspirated. The pelvis is washed with normal salt solution and then with fibrinogen solution. The pelvis is filled with fibrinogen through the catheter while simultaneously one tenth as much of 2 per cent clotting globulin is injected through the wall of the catheter with a syringe and needle. After five minutes, a firm cast of the pelvis and calices forms. This is removed by enlarging the pyelotomy incision. The coagulum frequently extrudes itself or may be removed by forceps, and brings with it all small stones that lie free within the kidney. Animal experiments conducted by Dees showed that no harm was done to the kidney by the retained coagulum or its intro-

duction, and the procedure was carried out in 21 patients without demonstrable ill effect.²⁶

We recently used the coagulum technic in a patient with multiple small stones in the kidney pelvis. The clot extruded itself intact on opening the pelvic wall, forming a perfect cast of pelvis and calices. All the calculi, including several small stones unsuspected in the preoperative x-ray films, were enmeshed in the clot. Air pyelograms assist greatly in determining beforehand whether this method is suitable, since unless the air surrounds all the stones in the calices of the kidney, the calculi are apt to be adherent and are not removed by the clot. Although this procedure has limitations, it has considerable value, and trauma to the kidney is minimal.

In Nesbit and Cummings's⁷ series, 31 per cent developed metastases after castration, in Emmett and Greene's series¹⁴ 35 per cent did so. On the merits of combined treatment, orchidectomy and stilbestrol, Herger and Sauer¹⁹ recently expressed the opinion that orchidectomy preceded or followed by stilbestrol does not offer any advantages over castration alone. Stilbestrol when given to patients whose symptoms recurred after orchidectomy was seldom helpful. They observed temporary benefit in 15 patients who had been on stilbestrol for a long time and then were castrated, whereas 4 showed no response. They conclude that castration after estrogen therapy may be of value, but that estrogen therapy begun after castration has failed is seldom effective.

DECAPSULATION OF THE KIDNEY

Opinions have varied considerably whether decapsulation of the kidney is beneficial in the treatment of certain renal conditions. The operation was advocated by Edebohls about forty years ago for chronic nephritis and was practiced for a while, but it soon lost its vogue because the results were disappointing. The benefits of renal decapsulation have been attributed to the production of a collateral circulation from the perirenal tissues, an increased blood supply from interruption of the sympathetic nerves and release of tension within the kidney. Whether such changes actually occur has been questioned. More recently decapsulation has been advised for renal lesions other than chronic nephritis, notably toxic changes due to bichloride of mercury poisoning, reactions from the sulfonamides and post-transfusion anuria. After a thorough review of this subject, Abeshouse²⁰ concludes that decapsulation has unquestionable merit in certain conditions and that the chief indications for its use are progressive oliguria and anuria. He advocates the operation in the nephrotic stage of chronic parenchymatous nephritis associated with uncontrollable edema and albuminuria, anuria from bichloride poisoning not relieved by other measures, anuria following sulfonamide therapy and post-transfusion anuria. Others who have had experience with these conditions, however, are not in agreement concerning decapsulation.

Deming²¹ points out that although there is little difference of opinion concerning the chief indications for decapsulation, — anuria and oliguria, — there is no definite proof that the operation is the factor that increases the urinary output and that many patients recover who are not operated on. He is not at all convinced that patients with bichloride of mercury poisoning recover because of decapsulation. Several years ago, Talbott²² expressed the following opinion concerning decapsulation of the kidney:

The subject of decapsulation is of interest in a general discussion of nephrotoxic agents, since this form of therapy

has been recommended in the treatment of anuria. It is my opinion that nothing is to be gained by decapsulating anuric kidneys. If resumption of urine flow follows decapsulation, restoration would probably have followed conservative treatment. Since decapsulation is an extensive operation and patients with anuria are acutely ill, additional insults may be fatal and are best avoided. Recently we had an unusual opportunity to study the effects of unilateral decapsulation in a young woman who developed anuria following a transfusion reaction. On the fourth day of anuria, the right kidney was decapsulated, and catheters were placed in both ureters. Resumption of urine flow began about twenty-four hours after operation. There was no difference, however, between the urine volume from the decapsulated kidney and that from the untouched organ. Six weeks later, after normal urine volume had been established for some time and the concentration of nonprotein nitrogen in the blood was almost normal, inulin and Diodrast clearances were done. The ureters were catheterized again so that each kidney could be studied separately. A marked reduction in the rate of formation of glomerular filtrate and in renal blood flow was observed. More significant was the comparison of the two kidneys. No striking difference between the kidneys was noted in any of the functions measured. A mathematical average of all functions, however, showed a slightly better performance by the untouched kidney in comparison with the decapsulated one. Our results are interpreted as implying that unilateral decapsulation in this patient had no beneficial action on renal function.

I know of no other observation on the effect of renal decapsulation so carefully controlled as this one. Since the patient mentioned above was operated on in 1942, I know of no other case of decapsulation for anuria at the Massachusetts General Hospital. There are, however, many who regard decapsulation as beneficial in the treatment of certain types of oliguria and anuria.

HYPERTENSION AND NEPHROPTOSIS

Of 133 cases of nephroptosis reported by Braasch and Goyanna,²³ only 16 showed hypertension, and in none of these was the nephroptosis considered the etiologic factor. The majority of patients with nephroptosis had blood pressures that were average or below average. Any compression of the blood vessels of the renal pedicle that might arise from the ptotic kidney was considered to be unlike the changes described by Goldblatt.

ENDOMETRIOSIS OF THE BLADDER AND URETER

Invasion of the bladder by endometrial tissue has been considered unusual, and only 58 authentic cases have been reported in the literature. Twelve additional cases reported by O'Connor and Greenhill²⁴ give one the impression that this condition is not so rare as was supposed. Cyclic bleeding, considered a typical symptom, was recorded in only two thirds of the patients, and gross bleeding occurred much less frequently than one would expect. The cystoscopic appearance of these tumors may or may not be that of so-called "chocolate cysts." They are described as elevated, congested and edematous, often with a bluish or blue-black cast. The tumor mass may increase during menstruation. Biopsy is an aid in their detection. Removal of the ovaries usually results in a disappearance of these lesions, but occasionally this step does not

that it was probably present and that there were two lesions of the gastrointestinal tract that need to be explained

For the moment let us say that she was pregnant and that her denial of pregnancy was false

DR. TRACY B. MALLORY It is only fair to say that, when presented with the results of the Aschheim-Zondek test, she changed her story

DR. CLIFFORD That also makes me change my story

With a lesion in that area of the stomach and another lesion elsewhere in the bowel, the first thing that comes to mind is Hodgkin's disease or lymphoma. A lymphoma can cause intermittent profuse bleeding, and it can involve as great an area of the stomach without extreme symptoms as was demonstrated in this case by x-ray examination. As I thought this case over, before I knew that she was pregnant, the positive Aschheim-Zondek test made me entertain one wild speculation, which I shall still mention, to explain multiple intestinal lesions without pregnancy. The Aschheim-Zondek test is positive without pregnancy with a chorionepithelioma or hydatid mole. These usually occur following a pregnancy, but there have been some rare cases of chorionepithelioma of extragenital origin, which presumably arose from teratomas, with metastases in the lungs, liver and brain and some in the intestine. The possibility of implants of a chorionepithelioma in the intestines is ruled out by her admission of probable pregnancy, as well as by the rarity of such a pathological finding. A Krukenberg tumor or colloid carcinoma, with implants in the lower intestine, should also be mentioned in passing. An interesting feature is that she had not had more signs of intestinal bleeding, this presupposes that the lesion was primarily in the wall and was invasive, perhaps a sarcoma. We have no proof that the mass noted on physical examination was a second tumor, which thereby forces me to depend on the x-ray evidence. I shall make a provisional diagnosis of a sarcomatous lesion in the antrum.

A PHYSICIAN Was a pelvic examination done on this woman?

DR. LAMAR SOUTTER Yes, she had an enlarged uterus, which was perfectly symmetrical and soft.

A PHYSICIAN Was there any connection between this and the abdominal mass?

DR. SOUTTER No, the abdominal mass was much higher than the record leads one to believe.

A PHYSICIAN Why does Dr. Clifford say sarcoma instead of carcinoma?

DR. CLIFFORD Primarily because of the extensive annular growth, the three-month story and the patient's age.

DR. MALLORY How would the appearance of this lesion in the stomach differ from that of an ectopic pancreas in the antrum, Dr. Lingley?

DR. LINGLEY Ectopic pancreatic tissue may produce a filling defect in the stomach that simulates carcinoma. The defect, however, is usually not annular but occurs rather more on one side.

DR. MALLORY Sometimes it produces an annular swelling of the sphincter, almost like hypertrophic pyloric stenosis.

DR. LINGLEY In this case there was ulceration of the mucosa, so that I have no hesitation in calling it a malignant lesion.

DR. SOUTTER Preoperatively we were quite uncertain what this patient had, but we thought that benign hypertrophy was a good bet. We made a large incision for exploratory purposes, and when we got in, we found a large mass at the pylorus. The peritoneum over it was glistening and intact. There were quite a number of enlarged nodes along the lesser curvature. The pylorus was obviously enlarged with growth of some sort, but whether or not it was pancreatic tissue we did not know. There was no muscular hypertrophy. We sent for a pathologist and gave him two nodes from along the lesser curvature. He could not make a diagnosis but thought that the lesion was probably benign. We believed that she should have a resection of the stomach because of obstruction. As there was a possibility that this was a malignant disease, it seemed that, to be adequate, the resection should be high. Since such a resection in that age group would not increase the mortality over that of a low resection, we did a high one. In order to get the anastomosis to lie transversely, with the best functional effect, we also had to remove a large amount of the greater curvature. We had difficulty at the lower end because the pancreatic tissue was close to the lesion, and we had to resect some of the pancreas with the specimen.

CLINICAL DIAGNOSIS

Carcinoma of stomach?

Sarcoma of stomach?

DR. CLIFFORD'S DIAGNOSIS

Sarcoma of antrum of stomach

ANATOMICAL DIAGNOSIS

Carcinoma of stomach with metastasis to one lymph node

PATHOLOGICAL DISCUSSION

DR. MALLORY We were unable to make a diagnosis on the gross specimen of the resected stomach. It did not seem to be as indurated or firm as we ordinarily expect a carcinoma to be. The possibility of lymphoma entered our minds. When the sections came through, it was quite obvious that the tumor was a scirrhous colloid carcinoma, which showed extensive infiltration of the wall of the stomach, and a single node out of the seven examined showed a small metastasis.

CASE 32171

PRESENTATION OF CASE

A twenty-year-old unmarried woman entered the hospital because of progressive abdominal discomfort

Three months before admission the patient noted a tendency to belch, especially soon after the evening meal and through the night. The eructations increased in frequency, and a month later the belched gas became foul smelling. Six weeks before admission nausea and excessive salivation developed, especially in the early morning. At about the same time the patient began to have intermittent diarrhea. Between periods of diarrhea the stools were usually normal, but on three occasions foul, black, sticky feces were passed. There were also intermittent episodes of abdominal discomfort and generalized crampy pain. She had lost 9 pounds in the two months before admission, although the appetite had been good. Two weeks before admission spontaneous vomiting immediately after meals began and persisted thereafter, although some meals were retained.

The last menstrual period began two months before admission and was normal, previously they had always been regular. The possibility of pregnancy was denied.

On physical examination there was diffuse, slight, lower abdominal tenderness accentuated in the subxiphoid region. There was a small, slightly tender, freely movable mass in the right lower quadrant near the midline. The breasts were slightly nodular.

The temperature, pulse, respirations and blood pressure were normal.

The red-cell count was 4,400,000, and the hemoglobin 12.7 gm per 100 cc. The urine had a specific gravity of 1.028 and was normal. A guaiac test on the stool was negative. The gastric contents showed 12 units of total acid and no free acid before histamine and 11 units of total acid and 10 units of free acid after histamine. X-ray examination of the stomach was somewhat unsatisfactory because the patient vomited most of the barium, but a definite annular defect about 3 cm long was seen in the an-

trum. There was only a very narrow channel through the antrum and pylorus leading to an essentially normal duodenal bulb. The rugal folds were swollen. The film of the chest was normal. Gastroscopy failed to visualize any lesion, peristalsis was normal, and there was no evidence of rigidity of the stomach wall within the range of the gastroscope.

On the third hospital day her family physician reported that an Aschheim-Zondek test done the day before entry was positive. Her symptoms continued unchanged.

An operation was performed on the eighth hospital day.

DIFFERENTIAL DIAGNOSIS

DR MILTON H CLIFFORD From the story alone,—the skipping of a menstrual period and later a positive Aschheim-Zondek test,—one might have been justified in attributing the original symptoms to nervous indigestion precipitated by the emotional trauma and the subsequent symptoms of nausea and vomiting to the onset of pregnancy. Certainly the story is that of an increasing partial obstruction in the upper intestinal tract, presumably a pylorospasm from organic or functional causes, with periods of intermittent diarrhea suggesting irritation in either the lower intestine or in the large bowel. She passed foul, black, sticky feces. In the absence of taking iron or bismuth by mouth, the assumption is that the black feces represented bleeding and that she had had at least one episode of intestinal bleeding. This could not have been a constant oozing in view of the negative guaiac test noted later and in view of the level of hemoglobin, which, although not normal, was essentially so. There were two definite findings—x-ray evidence of a lesion in the stomach and a presumable lesion low in the abdomen on physical examination. Before we go farther, I should like to see the x-ray films.

DR JAMES R LINGLEY This is a definite prepyloric lesion, which extends up both curvatures and involves about 3 or 4 cm of the antrum. It is annular in type, and I think that the mucosa throughout this area is completely destroyed. There is also a suggestion of shelf formation along its upper margin.

DR CLIFFORD It is of interest that gastroscopy showed no abnormality, but of course the lesion was in the antral area, which is visualized with difficulty gastroscopically. The most significant negative information from the gastroscopic examination is that peristalsis was normal and that there was no sign of rigidity.

The second lesion that presented on physical examination, the small, slightly tender, freely movable mass in the right lower quadrant, near the midline, is consistent with a mass in the small bowel. It might, however, have been informative to have checked the colon by a barium enema. I am going to take that finding at its face value and assume

drome of which hepatic cirrhosis is probably the most important part. The physical findings of jaundice, an enlarged liver, ascites, edema and spider angiomas are consistent. The laboratory findings are also consistent, so far as the low serum albumin, the positive cephalin-flocculation test, the low vitamin A in the serum and the increased prothrombin time are concerned. With the data at hand there is no way of determining whether the anemia was due to the deficiency or to blood loss from hemorrhage. The blood chemical findings at the time of his episode of dyspnea and confusion on the sixth day after examination resemble those reported in experimental liver injury, and in such cases the acidosis is said to be due to failure of the liver to convert lactic acid to glycogen. The only unusual laboratory finding in this case is the high white-cell count, which I am unable to explain on the basis of infection, either in the liver or elsewhere, or as due to a recent acute hemorrhage. Although a low white-cell count is almost the rule in cases of what might be called chronic cirrhosis of the liver, I believe that with more acute episodes of liver-cell destruction leukocytosis may be present. I remember one case of portal cirrhosis in which there was an unexplained white-cell count of 18,000, when the patient came to autopsy no other cause for the increased count could be found.

Is it possible to explain this picture on any other basis than that of cirrhosis of the liver? The large size of the liver suggests a malignant tumor, presumably metastatic. We are not told the character of the liver edge, but I think that the manifestations of liver insufficiency are too marked to make this as a single diagnosis, in addition, there is no evidence of a primary focus. A palpable spleen would be helpful at this point as further evidence against the liver enlargement's being due to metastatic malignancy. The only possible type of new growth that would fit in here, I believe, is a primary hepatoma superimposed on cirrhosis, but there are no positive findings by which one could logically make this diagnosis. It does not seem necessary to consider obstructive jaundice or, except for the increased white-cell count, an infectious process in the liver.

If we accept the diagnosis of cirrhosis of the liver, the next question concerns its type. The episode of jaundice at the age of twenty-one, which persisted for two months, brings up the probability that this patient died of a toxic or nodular cirrhosis, with the primary insult to the liver occurring many years previously. The large size of the liver at the time of admission is somewhat against this diagnosis and in favor of the more frequent alcoholic cirrhosis, but we are often reminded in the exercises of the fallibility of physical diagnosis when it comes to determination of the size of the liver. Toxic cirrhosis, which is also called subacute or healed yellow atrophy and usually represents the end results of

repeated episodes of liver-cell damage or destruction, also explains the leukocytosis.

There are two final points. One is whether or not the patient had a duodenal ulcer either three and a half years before or at the time of death. I do not believe that this can be answered, since he did not have a gastrointestinal x-ray examination during his hospital admission, which, incidentally, might also have shown the presence of esophageal varices. The second point concerns the terminal episode that immediately preceded his death, and this seems to me to be a vivid example of massive gastrointestinal hemorrhage. This presumably took place from a ruptured esophageal varix, although again one wonders remotely about the duodenal ulcer. He did not vomit blood, but this I believe has been recorded not infrequently in patients dying from such a cause.

I propose a diagnosis of liver failure due to toxic cirrhosis, with death resulting from hemorrhage from a ruptured esophageal varix.

DR TRACY B. MALLORY. Dr Volwiler, would you care to comment about the impressions on the ward?

DR WADE VOLWILER. The protein level of the blood, with the normal albumin-globulin ratio and the slightly lowered vitamin A level, did not help much with the diagnosis. They were just consistent with malnutrition.

We treated this man for acute liver disease, without success. He refused to eat, and regardless of whatever one gives in the way of supplements and fancy medicines, I am sure that the fundamental basis of liver-disease therapy comes down to a proper diet and enough of it.

I agree that an increased white-cell count can be explained by massive and diffuse hepatic-cell necrosis. In such patients white-cell counts up to 20,000 or 30,000 are not infrequent, with a preponderance of neutrophils, a shift to the left and many toxic granules.

CLINICAL DIAGNOSIS

Alcoholic cirrhosis of liver

DR SHORT'S DIAGNOSES

Toxic cirrhosis of liver, with esophageal varices
Terminal gastrointestinal hemorrhage

ANATOMICAL DIAGNOSES

Cirrhosis of liver, alcoholic type.
Hemorrhages in lungs
Bronchopneumonia
Peritonitis, acute generalized early

PATHOLOGICAL DISCUSSION

DR MALLORY. The autopsy showed cirrhosis of the liver. The liver at that time, whatever it may have been earlier, was small, weighing 1450 gm, perhaps 300 gm below what might have been ex-

DR CLIFFORD How much mucosal involvement was there?

DR MALLORY The mucosa was ulcerated away over the entire extent of the tumor.

Can you answer the question about the second mass, Dr Soutter?

DR SOUTTER There was no second mass

CASE 32172

PRESENTATION OF CASE

A fifty-five-year-old auto-supply dealer entered the hospital complaining of jaundice and abdominal swelling

At some indefinite period five or six months before admission the patient began to be troubled by "gas" in the abdomen and by increasing weakness. He continued to work until ten weeks before admission, when these symptoms, along with occasional nausea and vomiting, forced him to bed. Five weeks later he began having paroxysms of coughing and developed dyspnea. Two weeks before admission he became aware of a progressive uncomfortable swelling of the abdomen and of yellowness of the skin. He had never noticed any unusual color of the stools or urine. He complained of shooting pains in the arms and fingers and noticed tingling of the tip of the tongue. There had been marked wasting of the face, extremities and thorax, and an overall weight loss of some 15 pounds.

For ten or fifteen years the patient had consumed a fifth of a gallon of whisky daily. During that time his appetite was poor and he frequently went for a week at a time without eating any appreciable amount of food. He stopped drinking two weeks before admission.

Three and a half years before admission the patient entered another hospital because of gastrointestinal hemorrhage manifested by the passage of tarry stools. He received a blood transfusion and was discharged after a week, an x-ray diagnosis of duodenal ulcer having been made. There was no known gastrointestinal hemorrhage after that except for intermittent and, at times, fairly well marked bleeding from hemorrhoids. At the age of twenty-one years, the patient had jaundice, weakness and anorexia, which caused him to stop work for two months.

On physical examination the skin and scleras were moderately jaundiced. The tongue was beefy red, and the finer papillae were atrophied. A few fine crackling rales were heard at the base of the right lung. The protuberant abdomen bulged at the flanks, and there were a fluid wave and shifting dullness. The liver edge descended six finger-breadths below the ribs. A few spider angiomas were present on the skin of the chest and neck. There was moderate pitting edema of the legs and over the sacrum. All the extremities were weak,

and the outspread hands trembled. There were prominent internal and external hemorrhoids.

The temperature was 99.6°F, the pulse 125, and the respirations 20. The blood pressure was 120 systolic, 70 diastolic.

The red-cell count was 2,850,000, with 8.8 gm of hemoglobin. The white-cell count was 33,700, with 88 per cent neutrophils. The urine showed a specific gravity of 1.016 and gave a + test for albumin and bile; the sediment contained 10 white cells and a rare red cell per high-power field. Urobilinogen was demonstrable in a dilution of 1:200. A stool gave a negative guaiac reaction. The serum bilirubin level was 3.4 mg per 100 cc direct and 4.8 mg indirect. Other blood chemical findings were as follows: nonprotein nitrogen, 21 mg per 100 cc; protein, 4.2 gm, with 2.3 gm of albumin and 1.9 gm of globulin, and vitamin A, 0.3 unit per cubic centimeter. A cephalin flocculation test was equivocal at twenty-four hours and ++++ at forty-eight hours. The prothrombin time was 33 seconds (normal, 19 to 22 seconds).

On the second hospital day 700 cc of clear yellow ascitic fluid was obtained. Anorexia and weakness persisted. On the sixth day the patient was found sitting up in bed breathing deeply. He was drowsy and confused, complaining of numbness in the hands and feet. The serum bilirubin had risen to 5.2 mg per 100 cc direct and 7.8 mg indirect, and the carbon dioxide level was 20.6 milliequiv per liter. The chloride was 98 milliequiv per liter, and the sodium 136.1 milliequiv. With intensive dietary and intravenous therapy his condition improved slightly over the course of weeks. Anorexia and apathy made it impossible for a satisfactory high-calorie intake to be maintained. The liver edge was felt to be definitely receding. On the thirty-second hospital day the patient gradually became markedly dyspneic and cyanotic. The pulse was unobtainable, and the blood pressure was 88 systolic, 76 diastolic. He was sweating and apprehensive and complained bitterly of abdominal distress. Attempts to pass a Levine tube were abandoned because the patient could not swallow and became even more cyanotic during the procedure. Respirations slowed and eventually ceased about six hours after the onset of the severe dyspnea.

DIFFERENTIAL DIAGNOSIS

DR CHARLES L. SHORT With the possible exception of the episode of gastrointestinal bleeding that occurred three and a half years before this patient's admission, his entire medical history seems to point to disease of the liver. The story of a high alcoholic intake for ten or fifteen years and, perhaps more important, his periodically inadequate diet form a sufficient cause for the development of liver failure. The appearance of his tongue and the pains and weakness of his extremities are further examples of the development of a deficiency syn-

THE INADEQUACIES OF MEDICAL CARE

III THOSE CONCERNING ITS QUALITY

ONE topic rarely mentioned by the medical profession in discussions concerning medical care is its quality. It seems to be assumed that, because the science of medicine has advanced as far in the United States as in any other country of the world, all licensed physicians are equally proficient. Such, unfortunately, is not the case, and many things must be accomplished before the matter can be corrected.

The first step is to be sure that all medical students receive an adequate education. Although it is true that the majority of substandard schools have been forced to close, and that all the states but one

do not permit graduates of such schools to take examinations for licensure, the fact remains that many thousands of graduates of substandard schools are in active practice. Undoubtedly some of these physicians give better medical care than do certain graduates of approved schools, but the majority of them do not. There has been no practical way in which any kind of check could be made on their activities, since the majority are not acceptable as staff members of recognized hospitals, a matter that is discussed in greater detail below.

A corollary of adequate medical education is the responsibility of the medical school and teaching hospital to turn out physicians whose training has been in accordance with the existing demand. Undoubtedly the majority of medical-school graduates aspire to become certified by one of the specialty boards, — in fact, 80 per cent of the 21,000 medical officers serving with the armed forces so stated in a poll taken two years ago, — but it is obvious that such a superfluity of specialists would not serve to the best interest of caring for patients. The bulk of the profession must be composed — as it always has been — of physicians who are trained to give general medical care and who are sufficiently intelligent and self-effacing to refer their difficult cases to the specialist. This type of medical education requires only about half the time necessary for qualification as a diplomate, and if an appreciable number of medical schools and teaching hospitals were to foster and promote such training, great benefit would accrue.

Secondly, some attempt should be made to control the various cultists who are licensed to practice their particular vocations in many of the states. Nothing short of a change in laws can remedy this situation, but one shudders to think of how many cases of tuberculosis and cancer remain unrecognized, because of this, until it is too late for effective therapy. In spite of her tardiness in finally refusing to accept applications for licensure from graduates of substandard medical schools, it is to the credit of Massachusetts that, to date, her legislators have refused to recognize cultists, other than osteopaths, and even they are required to take the same examination as do the graduates of regular medical schools.

pected in a man of his size. It showed a diffuse cirrhosis with an extremely fine type of granularity, the characteristic gross picture of the cirrhosis seen in people with severe alcoholic histories. That was further borne out microscopically. In the early stages of alcoholic cirrhosis, large livers with intense fatty infiltration are the rule, and in the later stages the fat frequently disappears, but in both stages a characteristic type of hyaline degeneration is found in the liver cells. This is present in the great majority of the alcoholic cirrhotics and is rarely seen in the livers of those who do not give a history of alcoholism or at least in whom the possibility of alcoholism can really be excluded. I think that one is justified without question in making a diagnosis of alcoholic cirrhosis here. In contrast to many cases that one sees in the late atrophic stage, the process was still extremely active. A great many of the liver cells were currently undergoing this peculiar

form of degeneration, and others were frankly necrotic. There were a great many foci of leukocytes about the necrotic cells, which fits in well with the elevated white-cell count.

The other features of the case were relatively unimportant. The spleen was not so much enlarged as one would expect in view of the chronicity of the story, it weighed only 250 gm. The heart was slightly hypertrophied. There were widespread hemorrhages throughout the lungs, which were probably due to liver insufficiency. The kidneys were essentially normal. There was terminal infection — a frank pneumonia and an early peritonitis.

DR. SHORT: Did he have esophageal varices?

DR. MALLORY: Small varices were found but apparently none had ruptured, since there was no blood in the stomach or intestines.

One hundred and thirty-five years ago the need for some outlet for the literary, scientific and social productivity of the Society other than the simple publication of its transactions was appreciated. Thus, on June 5, 1811, a committee was appointed "to ascertain, if possible, who are the conductors of a publication entitled *The New England Journal of Medicine and Surgery*, with a view to determine the expediency of incorporating the Communications of the Society in the said publication." It is assumed that the conductors preserved their anonymity, for no further report was forthcoming.

History tells us, however, that *The New England Journal of Medicine and Surgery and the Collateral Branches of Science*, a quarterly, continuing after 1826 as *The New England Medical Review and Journal*, was united in 1828 with *The Boston Medical Intelligencer*, which had been published as a weekly journal since 1823, to form *The Boston Medical and Surgical Journal*—a name of hallowed memory and a journal, we trust, of continuing and increasing usefulness, published since 1928 as *The New England Journal of Medicine*. Thus the publication record of the *Journal* stretches back uninterruptedly to 1812, when *The New England Journal of Medicine and Surgery* made its first appearance—an endurance record for the New World!

The Society continued to publish its transactions independently until 1914, although in 1847 its president, Dr Jacob Bigelow, proposed that when the permanent fund of the Society amounted to \$10,000 the income should be devoted to the publication of a journal. This matter was indefinitely postponed, but on July 1, 1914, a direct affiliation with *The Boston Medical and Surgical Journal* went into effect, whereby a special department in that journal was created, under the editorship of the secretary of the Society.

The question of ownership of the *Journal* did not reach an encouraging phase until 1920, when the Council voted to enter into negotiations for its purchase. The current owners proving receptive, the *Journal* eventually passed into the hands of the Society for the sum of one dollar and other, no doubt less obvious, considerations. The reorganization took place in April, 1921, and Dr Walter P Bowers became the managing editor.

During the first year of the Society's proprietorship of the *Journal*, all members were assessed five dollars to defray part of the costs of publication. They thus received, whether or not as individuals they wanted it, a six-dollar journal for a dollar less than the regular subscription rate. This assessment has gone down as the circulation and advertising rates have gone up, until finally in 1945, as our correspondent states, not only did the members of the Society receive the *Journal* without cost, but the periodical actually made money for the Society. The circulation of the *Journal* has increased from some 4500 in 1921 to over 18,000 in 1946.

The editors accept the probability that the precise terms in which the Treasurer's report is necessarily couched are somewhat misleading, but they have ordinarily neither the time nor the inclination to be greatly disturbed over it.

MASSACHUSETTS MEDICAL SOCIETY

MARKING OF PRESCRIPTIONS FOR HABIT-FORMING DRUGS

The following statement from the Massachusetts Board of Registration in Pharmacy relative to the proper marking of prescriptions for habit-forming drugs should be of interest to all practicing physicians.

MICHAEL A TIGHE, *Secretary*

The Massachusetts Board of Registration in Pharmacy wishes to inform you that the Pure Food and Drug Division of the Federal Security Agency has recently ruled that Sections 502(d) and 503(b) relative to the marking of prescriptions ("Warning—May be habit forming") must be carried out to the letter of the law.

For your information, these sections of the law read as follows:

Section 502. A drug or device shall be deemed to be misbranded (d) If it is for use by man and contains any quantity of the narcotic or hypnoc substance alpha eucaine, barbituric acid beta-eucaine, bromal cannabis carbomal chloral coca cocaine, codeine heroin marihuana morphine, opium paraldehyde peyote, or sulphomethane or any chemical derivative of such substance which derivative has been by the Administrator after investigation found to be, and by regulations designated as habit forming unless its label bears the name and quantity or proportion of such substance or derivative and in juxtaposition therewith the statement "Warning—May be habit forming."

Section 503. (b) A drug dispensed on a written prescription signed by a physician, dentist or veterinarian (except a drug dispensed in the course of the conduct of a business of dispensing drugs pursuant to diagnosis by mail) shall if—

(1) such physician, dentist or veterinarian is licensed by law to administer such drug and

(2) such drug bears a label containing the name and place of business of the dispenser, the serial number and date of such prescription and the name of such physician, dentist or veterinarian, be exempt from the requirements of Section 502 (b) and (c) and (in case such prescription is marked by the writer thereof as not refillable or its refilling is prohibited by law) of Section 502 (d).

These two sections are self-explanatory, but it should be emphasized that it is necessary to place on the container the following, "Warning—May be habit forming." This inscription is required on every prescription item, including refills if the prescribing physician does not bar a refill. In other words, the only time that the pharmacist does not put the "Warning—May be habit forming" label on a prescription is when the doctor marks the prescription "Not to be repeated."

A third difficulty arises from the fact that mere graduation from an approved medical school is no guarantee of an efficient and up-to-date practitioner. The science of medicine has advanced and is advancing so rapidly that a graduate of five or ten years is neglecting the majority of his cases of serious illness if he applies to them the knowledge that was his on graduation. He must constantly keep himself professionally "fit" — by reading, by refresher courses and by contact with his associates. This, of course, is much easier for the physician on the staff of a large hospital, particularly a teaching unit, but it is still the responsibility of all who consider themselves to be practitioners of medicine. Unfortunately, as previously mentioned, graduates of substandard schools, the very men who would benefit most by contact with others, are usually denied hospital privileges. One hospital in Massachusetts has already taken steps to remedy this situation. All such physicians within the community have been invited to attend ward rounds, staff meetings and clinicopathological conferences. Those who give evidence of a fair amount of medical knowledge and of a desire to improve themselves will be permitted to take patients to the hospital and to care for them, under supervision, except for major surgery and operative obstetrics. As a result, these men should show marked professional improvement, their patients will be assured adequate hospital facilities and the general health of the community should be raised. On the other hand, there will undoubtedly be some men who will scorn this help or who will be unable to profit by it, such practitioners obviously contribute little toward improvement of medical care. The adoption of this constructive scheme in other community hospitals deserves serious consideration, it has received the enthusiastic support of the Massachusetts Medical Society and the Massachusetts Hospital Association.

Another problem tied up with the quality of medical care concerns the question, Who is qualified to do what? Obviously a surgeon in a small community ordinarily should not perform a Wertheim operation, nor should he remove a tumor of the brain or lung. But there is nothing to prevent him from doing so if his regard for the well-being

of the patient is so slight that he refuses to refer the case to a properly qualified surgeon. The American College of Surgeons and the American Board of Surgery have done much in recent years to label those who have had adequate training in surgery, and even boards of surgical specialists have been established. But all this accomplishes little unless the layman is taught that what one surgeon is capable of doing is not necessarily within the ability of another.

The final inadequacy that lowers the quality of medical care is a lack of diagnostic facilities. If the modern physician is denied the help of x-ray, chemical, pathological and bacteriological laboratories, his ability to diagnose most of his cases of serious illness falls to a level that is comparable with that of the family doctor of fifty years ago, — if, indeed, it does not fall lower, — and treatment of the patient accordingly suffers. Such laboratories can be maintained only by groups of physicians, clinics and hospitals, and this is undoubtedly one of the chief reasons why recently graduated physicians shun small cities and rural communities. The banding together of physicians in groups and the establishment of well equipped health centers and hospitals in areas that need them would do much to relieve the situation.

Several of the factors contributing to the quality of medical care concern state boards of licensure and departments of health. On the other hand, two of them — keeping professionally "fit" and practicing according to one's ability — are the direct responsibility of the practicing physician. Undoubtedly, however, the health of the Nation would be improved if the layman could be taught how to obtain the medical care that he specifically needs.

QUARTER CENTURY OF PROGRESS

A LETTER appearing elsewhere in this issue of the *Journal* serves at least to call attention to one interesting fact, namely, that the year 1946 marks the twenty-fifth anniversary of the Massachusetts Medical Society's ownership of the *Journal*. It may not be amiss to state that they have been years of mutual progress.

LOW-SODIUM DIET AND FREE FLUID INTAKE IN THE TREATMENT OF CONGESTIVE HEART FAILURE*

A Preliminary Report

WILLIAM C BRIDGES M D,† EDWIN O WHEELER, M D,‡ AND PAUL D WHITE, M D §

BOSTON

TRADITION is hard to break. Doubtless since the time of Adam, dropsy has been traditionally treated by the limitation of fluid intake, a natural result of the observation of the accumulation of water in the body tissues. Despite the assembly of clear-cut evidence in laboratory and clinic that restriction of common salt and of sodium in any form is much more important than is restriction of water, the practical application of this idea in effective form has been extremely slow. In a few places in this country where knowledge along this line was far more advanced than elsewhere, the usefulness of this treatment was appreciated, but the lag in the way of general acceptance—or rather, of adequate distribution—of this valuable information has been great, owing in part, doubtless, to the distractions of World War II.

The custom of late years at the Massachusetts General Hospital of casually advising a low-fluid and low-salt intake for congestive heart failure has during the past year given way to the far more successful application of a low-sodium and free fluid intake. In the fall of 1944, we were prompted to adopt this procedure on reading of Lyons's¹ experience in New Orleans following the vigorous report of Schemm,^{2,3} who in turn was stimulated by his former preceptor, Newburgh.

Evidently, the secret of the success of this treatment in many cases is not merely to give a so-called "low-salt" diet, which may contain anywhere from 3 to 6 gm of sodium chloride, but to give a low enough salt intake, which may need to be as little as 2 gm or even less. This in turn allows one to permit, in fact to encourage, free intake of fluids for the relief not only of edema but also of thirst. The heart is able to support the increase of fluid intake, despite former fears, and the kidneys are

able to work much more effectively. Nor is it necessary to carry out this treatment in the hospital in all cases, although it is usually best to begin here; ambulatory patients can follow the regimen at home if properly instructed and if able to secure such an important item in the diet as salt-free bread. The amount of salt in ordinary bread alone, especially in the case of habitual bread eaters, is apparently sometimes great enough to make the difference between the persistence and the clearing of edema. Moreover, one should not wait for dropsy or even slight grades of systemic edema to appear, dyspnea and pulmonary edema are likewise helped, and the salt restriction may be usefully applied early in the treatment.

That sodium chloride plays a leading part in the development of edema was pointed out in 1901 by Achard and Loeper.⁴ These investigators fed 10-gm samples of salt to patients with heart trouble and found that it was not excreted in the urine in twenty-four hours, as it was in certain other patients without heart disease, nor was the blood level of sodium chloride increased. From this they concluded that the ingested salt contributed to the edema. This experiment was not utilized in the treatment of cardiac edema until 1903, when Merklen⁵ treated a group of edematous patients and nephritic patients with a milk diet without extra salt. He chose milk for this diet entirely because of its low salt content. The edema cleared under this regimen. Karell⁶ had found in 1866 that a diet of 600 to 800 cc of milk a day was helpful in the care of edematous cardiac patients but he had little knowledge concerning the mechanism of its beneficial effects. Another study at about the same time as Merklen's, made by Widal and Lemierre⁷ and conducted in the same kind of patients, suggested that fluid intake need not be restricted to the extremely low levels set by Karell, for in their patients 3000 cc. of milk was permitted a day, without the reduction of the efficacy of the treatment. Thus, one of

§Physician, Massachusetts General Hospital.

DEATHS

ELLIOTT—John J Elliott, M.D., of West Roxbury, died March 29. He was in his fiftieth year.
Dr Elliott received his degree from Hahnemann Medical College and Hospital of Philadelphia in 1921. He was a member of the New England Obstetrical and Gynecological Society and the American College of Surgeons.
His widow survives.

PIPER—Frank J Piper, M.D., of Framingham, died April 4. He was in his forty-ninth year.

Dr Piper received his degree from Tufts College Medical School in 1924. He was a veteran of the Southwest Pacific, having seen service as a flight surgeon at Guadalcanal, the Admiralties and the Philippines. At the time of his death Commander Piper was on terminal leave after serving nearly four years in the Navy Medical Corps. Before entering service he was president of the staff and assistant to the surgical service of the active staff of the Framingham Union Hospital.

His widow, three daughters, his parents and a sister survive.

ROSENAU—Milton J Rosenau, M.D., of Chapel Hill, North Carolina, died April 9. He was in his seventy-eighth year.

Dr Rosenau received his degree from the University of Pennsylvania School of Medicine, Philadelphia, in 1889. For twenty-five years he was connected with Harvard Medical School, first as professor of preventive medicine and hygiene and later as professor of epidemiology at the Harvard School of Public Health. From 1913 to 1922 he was director of the School of Public Health of Harvard University and the Massachusetts Institute of Technology. He was a world renowned authority on preventive medicine and sanitation, and since 1935 had been director of the University of North Carolina School of Public Health. He was a fellow of the American Medical Association and a member of the Association of American Physicians and the Society of American Bacteriologists.

His widow, a son, a daughter and a stepson survive.

MASSACHUSETTS DEPARTMENT
OF PUBLIC HEALTH

NOTES

John J Poutas, M.D., M.P.H., has resumed his duties as director of the Division of Local Health Administration, Massachusetts Department of Public Health, having returned from overseas duty in the European Theater. Prior to returning to this country, Lieutenant Colonel Poutas served as chief of the Epidemiology Branch of the Preventive Medicine Division, Office of the Theater Chief Surgeon. His duties will include supervision of the eight district offices of the department and the nursing, nutrition, social-service and sanitation bureaus.

Roy F Fecmster, M.D., recently acting director of the Division of Local Health Administration, Massachusetts Department of Public Health, has returned to his former position as director of the Division of Communicable Disease.

Dwight J Mulford, Ph.D., has been appointed laboratory chief of the Blood Processing Laboratory in the Division of Biologic Laboratories, Massachusetts Department of Public Health. This laboratory is especially designed for the fractionation of blood plasma into albumin, immune serum globulin, fibrin foam, fibrin film and other fractions of value in medicine, surgery and public health.

Otto C Yens, M.D., has been appointed supervisor in charge of Crippled Children Services in the Massachusetts Department of Public Health. Prior to his appointment, Dr Yens held the rank of lieutenant colonel in the Medical Service of the 117th Evacuation Hospital, United States Army.

Ruth Alida Thomas, M.A., C.P.H., has joined the staff of the Bureau of Health Information, Massachusetts Department of Public Health. Miss Thomas was formerly assistant professor in the Department of Hygiene and Bacteriology, Smith College. She also served as consultant in the Medical

Intelligence Branch of the Preventive Medicine Division, Office of the Surgeon General, United States Army.
Alexander A Robertson, formerly chief sanitary officer with the Newton Health Department, is now serving with the Massachusetts Department of Public Health as supervising health-district sanitary officer.

John B Skinner, M.S., has been appointed director of the Division of Occupational Hygiene of the Massachusetts Department of Labor and Industries. Mr Skinner has been an engineer with the department since 1941. He succeeds Mr Manfred Bowditch, who retired from state service to assume the position of field director of the Saranac Laboratory, Saranac Lake, New York.

CORRESPONDENCE

THE JOURNAL PAYS ITS OWN WAY

To the Editor Why should not the *Journal's* financial success be fully recognized? Despite the fact that the members of the Massachusetts Medical Society have always received their copies of the *Journal* at a figure below the usual subscription rate, even from the earliest years of the Society's ownership, the annual report of the Treasurer has consistently ignored this basic fact and presented the fiscal affairs of the *Journal* as if the publication were run at a loss, the deficit being made up by a benevolent grant in the form of an appropriation by the Society.

It appears to me high time that the members of the Society realize that they have never paid full rates for their subscriptions, that their per capita annual assessment (call it "appropriation" if you like) has steadily decreased under the administration of two able managing editors, Dr Walter P Bowers and Dr Robert N Nyc, and that in 1945 not only did they receive their copies of the *Journal* without cost, but the *Journal* actually made money for the Society. Let us give credit where credit is due and stop speaking, writing and thinking of the *Journal* as if it were a drain on the Society's resources.

266 Beacon Street
Boston 16

JOSEPH GARLAND, M.D.

NOTICES

ANNOUNCEMENTS

Dr F H Capodicci, having been released from military service, announces the opening of an office for the general practice of medicine at 247 Harvard Street, Dorchester.

Dr Leo J Cass, having returned from military service, is resuming the practice of internal medicine at 1101 Beacon Street, Brookline, and 20 Ridgfield Road, Winchester.

Dr Lewis S Pilcher announces his return to the practice of general surgery with offices at 43 Parker Street, Newton Centre, and 12 Bay State Road, Boston.

Dr George C Prather, having returned from military service, announces the reopening of his office for the practice of urology at 1180 Beacon Street, Brookline.

NEW ENGLAND ROENTGEN RAY SOCIETY

The next meeting of the New England Roentgen Ray Society will be held at the Harvard Club of Boston on Friday, May 17, at 5 30 p.m. Dr A C Christie will present the Holmes Annual Lecture, his subject being "The First Fifty Years of Radiology. The elements that have contributed to its growth as a great medical specialty."

NEW ENGLAND HOSPITAL FOR
WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, May 2, at 7 15 p.m. in the classroom of the Nurses' Residence. Miss Bernice W Billings, R.N., will speak on the subject "Program of the Boston Tuberculosis Association." Dr Elizabeth O'Neil will be chairman.

(Notices continued on page xv)

place, no salt or soda is to be used in cooking or at the table, and one should not employ salt substitutes that contain sodium in any form. Second,

The advantages of this form of treatment are threefold. It frequently enables one to control edema that cannot be controlled with the usual

for gas and indigestion must not contain sodium, calcium salts are helpful as substitutes

indeed, these diuretics can frequently be entirely eliminated. Lastly, it enables patients to take

their patients, who had marked edema, could tolerate this amount of milk a day when salt was withheld from the diet (Fig 1)

As is widely known, however, even up to the present time edematous patients have in general been treated by the restriction of both salt and water. This was true at the Massachusetts General Hospital. Prior to the latter part of 1944 patients with congestive heart failure were treated with a diet containing 4 to 6 gm of sodium chloride a

to 6000 cc a day — and a low-sodium, neutral-ash diet as a means of controlling cardiac edema. He believes that the reaction of the diet is extremely important — in other words, that it is more helpful to keep the pH of the diet within limits than its sodium content.³

PLAN OF TREATMENT

During the past year we have treated patients with congestive failure with a diet quite low in

FIGURE 1

day, and the fluid intake was restricted to 1000 to 1500 cc a day.

In 1934, Newburgh and Lashmet⁸ studied the edema of nephritic patients. They pointed out the fallacy of restricting water in its treatment and the value of restriction of sodium as a means of limiting extracellular fluid.

Investigation of the relation of salt and water to the control of cardiac edema was not adequately reported further until 1941, when Schroeder⁹ clearly showed that sodium was the important factor to be considered, and that provided its intake was held at low levels, the water intake could be raised to 4000 cc a day without the formation of more edema. This problem was also considered by Proger et al,¹⁰ by Ellis¹¹ and more recently by Schemm^{2,3}. The last-named worker advocates the use of extremely large rations of water — 5000

sodium chloride, in addition to the usual digitalis and diuretics. Before a consideration of the advantages and disadvantages of the low-sodium diet is undertaken, its composition should be presented. To begin with, the diet used in the treatment of patients with congestive failure has contained about 700 mg of sodium in an amount of food equivalent to 1800 calories. If the food tastes too flat, patients are allowed ammonium chloride in the salt shaker in the place of sodium chloride. The diet has yielded a neutral ash, although its reaction probably has little significance, since ammonium chloride is given. In the body the ammonia forms urea and the chloride is set free to neutralize the excess sodium. We have not attempted to balance alkaline-forming and acid-forming foods.

There are certain precautions that must be strictly adhered to in following such a plan. In the first

50 mg per 100 cc. He was digitalized and given the earlier cardiac diet of this institution, which contained 6 gm of sodium chloride a day. Fluids were restricted to 1500 cc a day. Under this regimen, however, there was little change in the patient's condition and the response to Mercupurin was poor. On the 7th hospital day, he was placed on the low-sodium, neutral-ash diet and the water intake was increased to 3000 cc a day. The edema cleared rapidly and the fluid in the left pleural cavity almost disappeared. The nonprotein nitrogen decreased to 36 mg per 100 cc. The patient was discharged to a nursing home on the 17th day, 9 days after the neutral-ash diet and increased water intake had been begun. He has continued to do well from the standpoint of his congestive heart failure.

CASE 4 (Fig 5) A 60-year-old baker with coronary and hypertensive heart disease had had congestive failure since 1943 and for many months had required weekly mercurial diuretics, in addition to his acid-forming diuretics. Besides this treatment he had followed a salt-poor diet and had restricted his fluid intake to 800 cc a day. He continued to feel miserable and complained of epigastric distress on this regimen. The mercurial injections were followed by marked prostration, lasting for several days after each injection. On March 22, 1945, he was started on the low-sodium, neutral-ash diet and was allowed fluids freely. Since then he has felt a great deal better and has required no mercurial injections.

FIGURE 5

His sleep has been greatly improved, and he has been able to work every day, whereas formerly his activity had been markedly restricted. Prior to the initiation of this regimen he had great thirst and found it extremely difficult to restrict his water intake. He is no longer troubled in this way and continues to get along comfortably on the same small amount of fluid a day.

Comment. This case shows how successful this form of treatment may be in an ambulatory patient.

CASE 5 (Fig 6) A 59-year-old woman had had hypertensive heart disease with congestive heart failure for 4 years. She required mercurial injections weekly to

control her edema. On February 26, 1945, she was admitted to the Phillips House with slight pitting edema of the ankles and hepatomegaly. The low-sodium, neutral-ash diet was prescribed, and water was given up to 3000 cc daily. The

FIGURE 6

edema cleared on this form of treatment, and the patient required no mercurial injections for the 10 days she was in the hospital. Subjectively she felt a great deal better.

SUMMARY

Restriction of sodium to levels of 700 to 1000 mg (equivalent to 1.75 to 2.63 gm of sodium chloride) every twenty-four hours is helpful in the control of certain cases of congestive heart failure in which digitalis and mercurial diuretics are ineffective or not entirely satisfactory.

Water may be given freely, provided that the sodium intake is held to a minimum. Large water intakes may be of advantage in the elimination of edema, but this is probably a temporary phenomenon.

This regimen does not replace rest, digitalis and diuretic therapy but is a valuable adjunct to the treatment of obstinate congestive failure. In general, it has not been adequately used.

Five representative cases are reported.

The authors express their appreciation to Miss Shirley Wells for her help in arranging and analyzing the diets used in this study.

more water than they otherwise could. Frequently those treated by the old regimen have been extremely thirsty.

There are also disadvantages, however. The chief of these are that a few patients find it difficult or impossible to obtain such a diet, especially those who eat their meals in boarding houses and restaurants, and that patients frequently complain of the flat taste of food, particularly during the early stages of the diet. Although these criticisms are difficult to overcome, the marked relief that patients often obtain from their distressing cardiac symptoms, notably dyspnea and insomnia, and from frequent mercurial injections overweighs these disadvantages.

We are not as yet in a position to confirm Schemm's belief that a water intake of 5000 to 6000 cc a day is more beneficial than one of 2000 to 3000 cc, but we are sure that the water intake formerly recom-

function. For example, if a given renal mechanism can concentrate urine to a specific gravity of only 1.010, it will require at least 3000 cc of water a day for the kidneys to eliminate the metabolic waste products in twenty-four hours. Should the patient develop an intercurrent infection, even larger amounts of fluid will be required to take care of this loss through evaporation from the skin and lungs.

RESULTS

So far we have studied the effect of the low sodium diet on 64 patients, and have encountered varying degrees of success. Seventeen patients obtained much help, 15 moderate benefit, 8 slight benefit, and 7 no benefit. In the remaining 17 cases, either the patients were unco-operative or insufficient data regarding their response to the diet are available. Five cases will be briefly reported to illustrate the effect of this regimen.

CASE 1 (Fig. 2). A 67-year-old man was admitted to the hospital in 1935 with a diagnosis of acute myocardial infarction. During convalescence from this illness he developed congestive failure. He was treated for this with digitalis, which he has continued to take. In the fall of 1942, he developed ankle edema, which has persisted up to the present time. In December, 1944, he developed ascites, which required abdominal paracentesis. Since that time he has had to have several paracenteses for recurring ascites.

The patient was readmitted to this hospital on October 26, 1945, with marked ascites, ankle edema and pulmonary edema. An analysis of the diet that he had been receiving at home indicated that he had been taking 10.6 gm of sodium chloride and 800 cc of fluid a day. He was put on a regular house diet containing 2 gm of salt a day and 1800 calories and was allowed as much water as he desired. He was permitted to continue taking 0.1 gm of digitalis a day, as he had been doing at home. Under this treatment he had marked diuresis and his general condition markedly improved, with disappearance of both the ankle edema and the ascites. On the 10th hospital day, — 8 days after he had been put on the diet containing 2 gm of salt, — the daily amount of sodium chloride was further decreased to 1.5 gm and the daily water intake was fixed at 1750 cc. Owing to the fact that the patient had already lost most of his edema, this had little new effect.

Comment. This case illustrates extremely well how, in some cases, edema can be controlled simply by lowering the salt content of the diet.

CASE 2 (Fig. 3). A 39-year-old truck driver had a pericardial resection for constrictive pericarditis in October, 1944. Following the operation he continued to require Mercurpurin every other day for anasarca, and this, as is frequently the case, was extremely fatiguing. In addition to this complaint, he had cramplike pains in the epigastrium following each injection of Mercurpurin. On November 24, he was placed on a low-sodium, neutral-ash diet and the water intake was increased from 1500 to 2500 cc a day. After he had been on this form of treatment for 23 days without mercurial injections, the edema decreased slightly and the breathing improved. The weight showed a slow increase, apparently because of a normal increase in body tissue. The patient was discharged in December.

He has continued to follow the diet and to maintain the fluid intake at 2500 cc a day. When last seen in July, 1945, he had considerably improved and had required Mercurpurin injections only four times in the last 6 months.

CASE 3 (Fig. 4). A 73-year-old man had had hypertensive heart disease since 1943. In January, 1945, he developed congestive failure and was admitted to the Baker Memorial Hospital. On admission he had moderate ankle and sacral edema and a left hydrothorax. The nonprotein nitrogen was

FIGURE 4

mended was often distinctly inadequate. The optimal amount of water in twenty-four hours on such a regimen has not been established, and we ourselves have not as yet adequately investigated this subject. The restriction of fluid as practiced in the past does not seem to have a physiologic basis. There are strong indications that under certain conditions, notably in cases in which there is a diminished renal function and the kidneys can no longer concentrate the urine to a specific gravity great enough to eliminate the waste products of metabolism in the normal volume of urine, a daily intake of water higher than 1500 cc is essential. Cardiac patients frequently have diminished renal

untreated and when they were treated by the ingestion of 1 ounce of whisky immediately at the onset of the attack was repeatedly measured. The amount of work that could be performed before pain was precipitated was determined in 21 patients at varying intervals up to ninety minutes after a

Five patients had at some time in the past attempted to obtain relief from attacks of angina pectoris by drinking whisky. One had obtained no relief, the remaining 4, however, believed that whisky had been beneficial. The following examples illustrate their experience. One patient (I K),

single 1-ounce dose of whisky, and this was compared with the usual performance of the patient while on ineffective or placebo medication. The amount of work that could be performed before pain was precipitated was determined in 9 patients who had taken 1 ounce of whisky four times daily for one week, including the morning of the test. Lastly, to demonstrate a possible reflex effect of alcohol, the amount of work required to precipitate pain was determined in 8 patients who exercised while holding 1/2 ounce of whisky in the mouth.

RESULTS

Effect of Alcohol on Duration of Attacks of Angina Pectoris

One patient (M.L.) whose untreated attacks averaged sixty-two seconds in duration demonstrated a decrease in the duration of pain to an average of forty-six seconds when given 1 ounce of whisky immediately at the onset of an attack (Fig 1). In the remaining 7 patients, no measurable effect occurred (Table 1 and Fig 1).

after developing chest pain, walked for fifteen minutes to obtain a drink of whisky, relief occurred five minutes after ingestion of the liquor and the cessation of walking. Another patient (R.S.) ob-

ALCOHOL IN THE TREATMENT OF ANGINA PECTORIS*

SAMUEL STEARNS, M D,† JOSEPH E F RISEMAN, M D,‡ AND WILLIAM GRAY, M D §

BOSTON

THE earliest description of angina pectoris, that of Heberden¹ in 1786, refers to "the relief afforded by wine and spirituous cordials." Since then alcoholic beverages have frequently been recommended or at least permitted in the treatment of angina pectoris, but few efforts to evaluate such therapy have appeared in the literature. The present study was carried out to obtain an objective evaluation of the use of alcohol in the treatment of angina pectoris.

SUMMARY OF THE LITERATURE

The comparative value of brandy, carminatives and nitroglycerin in the treatment of attacks of angina pectoris was studied in 1934 by Evans and Hoyle.² Patients kept a record of two-week periods, noting the number of attacks, the duration of pain and the effect of medication. Nitroglycerin was followed by great or moderate relief in 59 per cent of the cases. Approximately half the patients reported a similar result with brandy or carminatives. Objectively, 1 of 11 patients was able to do more work following the prophylactic use of brandy.

White,³ without advancing statistical or experimental evidence, has named alcohol as the most effective drug, next to nitrites, in the treatment of angina pectoris.

The drinking habits of 750 patients with angina pectoris and of a control group have been reviewed by White and Sharber.⁴ No significant differences were found in the percentages of nondrinkers and moderate drinkers in each group, there were, however, 67 patients among the controls who drank to excess, compared to 9 excessive drinkers with angina pectoris. One of the latter had survived for twenty-four years following the onset of angina pectoris, despite a daily intake of 1 quart of whisky. It was concluded that although alcohol neither caused nor prevented angina pectoris, excessive

drinking was rare in the past history of patients with this disease and that in occasional cases alcohol might prevent or relieve attacks.

Levy⁵ also noted that the longest-lived of a large group of patients with angina pectoris was also the heaviest drinker.

MATERIALS AND METHODS

Observations were made on 19 men and 2 women, aged thirty-nine to seventy-five years, with angina pectoris of six months' to fifteen years' duration. None were in congestive failure, and only 1 had had a recent cardiac infarction. Of 11 patients in whom a history of the use of alcoholic beverages was recorded, 2 were total abstainers and 9 were infrequent or moderate drinkers. The heaviest drinker used not more than 2 or 3 ounces of whisky on any one day.

Each patient had been a regular weekly visitor to the Angina Pectoris Clinic of the Beth Israel Hospital for four months to thirteen years, during which time the objective response to a wide variety of medications, including nitroglycerin, had been repeatedly determined.^{6,7} Six patients showed a marked response to medication, 7 a moderate response, and 8 little or no response. The patients were therefore classified as belonging to Group 1, Group 2 and Group 3, respectively, according to the criteria previously described.⁷

At each visit, patients were questioned concerning the number of attacks of angina, the number of nitroglycerin tablets used and the amount of physical and emotional stress experienced during the previous week. The patients' ability to work was then determined by the Standardized Exercise-Tolerance Test,⁸ which consists of continuously ascending and descending a two-step staircase in a cold room (about 50°F) until angina develops. Only one test was performed on a given day, and no test was done if the patient had taken nitroglycerin in the preceding two hours. During the period of the tests with alcohol, patients received only placebo or other ineffective medication.

The following observations were made. In 8 patients, the comparative duration of induced attacks of angina pectoris when the patients were

concentration of alcohol does not accumulate in the blood stream in this time, any clinical response following the drinking of 1 ounce of whisky is probably due to a reflex or psychogenic effect. That alcohol does exert a reflex effect on the cardiovascular system has been shown by many studies. Brooks⁹ observed that 10 cc of 50 per cent alcohol introduced into the mouth of an unanesthetized dog resulted in an immediate sharp rise in blood pressure, whereas much larger doses given through a gastric fistula had no immediate effect. Lieb¹⁰ found that in man a drink of 5 cc of undiluted whisky produced a small rise in blood pressure within one minute. Dixon¹¹ observed that the pulse was transiently accelerated by taking into the mouth whisky, mustard, hot water or other stimulants of the mucous membrane. Subsequently it was demonstrated by Grollman¹² that a dose of 15 cc of alcohol produced in nondrinkers a transient rise in pulse, blood pressure and cardiac output within ten minutes of ingestion. He attributed these effects to stimulation of vasomotor centers by afferent impulses arising in the mouth, pharynx and esophagus.

In the present study, such reflex mechanisms were not of therapeutic importance, for angina pectoris was neither prevented nor decreased in duration by exercising the patient with whisky held in the mouth.

Vasodilator Mechanism

The vasodilating effect of alcohol on cutaneous vessels is well illustrated by the flushing and sweating that follow the taking of whisky. This effect has been shown experimentally to occur following the absorption of alcohol. Lieb,¹⁰ for example, showed that well diluted whisky had no cardiovascular effect until sufficient time for absorption had elapsed. Grollman¹² observed a rise in blood pressure, pulse and cardiac output in habitual drinkers as well as in nondrinkers within fifteen to thirty-five minutes after the ingestion of 35 cc or more of alcohol. This he considered to be compensatory to the cutaneous vasodilatation that would otherwise have resulted in a fall in blood pressure.¹²

Although a coronary vasodilating action has been assumed for alcohol,¹⁴ there is little experimental evidence that this occurs. Dixon¹¹ found that perfusion of an isolated segment of the coronary artery of a rabbit with 0.1 to 0.2 per cent alcohol in saline solution caused extremely slight vasodilatation. Sulzer¹⁵ observed that the first noticeable effect of alcohol on the coronary flow of a dog heart-lung preparation was invariably a decrease. An increase in concentration of alcohol from 0.13 to 0.21 per cent produced a further decrease of 17 per cent in coronary flow. Gilbert and Fenn¹⁶ found that the slow intravenous injection of 0.3 cc of 80 per cent alcohol per kilogram of body weight

into the intact dog caused no increase in coronary blood flow, although increases of up to 50 per cent were obtained following the use of various theobromine derivatives. Such concentrations of alcohol approximate the intoxication level in man¹⁷ and are not produced by ordinary therapeutic doses.

In the present study, any coronary vasodilatation that may have occurred was not of therapeutic value.

Central-Nervous-System Mechanism

Pharmacologists teach that although ethyl alcohol superficially appears to produce stimulation, it is actually a depressant of the central nervous system.¹⁴ It has been stated that blood concentrations considerably lower than those associated with clinical intoxication may impair the function of the higher centers in man.¹⁷ By this mechanism alcohol is probably capable of producing the observed effects of decreasing anxiety, diminishing attention to pain and promoting a sense of well-being.¹⁸

Regardless of its physiologic effect, the psychogenic effect, real or imaginary, has been commented on by many clinicians, including Osler¹⁹ and Brooks.²⁰

In this study, 7 of 9 patients who drank 1 ounce of whisky four times daily for one week reported subjective improvement. Two of these had no attacks of angina during the week of treatment. Objectively, one of them showed a 23 per cent increase in ability to exercise and another a 33 per cent decrease. The remaining 5 were able to do no more work under standardized conditions. Since similar results—that is, subjective without objective improvement—were noted in patients treated by multiple small doses of opiates or barbiturates,²¹ it is not improbable that alcohol is also capable of decreasing attention to pain or of increasing the threshold of awareness of pain. Two patients were made subjectively worse, one stopping the medication because of the increased severity and frequency of anginal attacks. The mechanism of such unfavorable reactions is not obvious.

Judging from the literature, it is difficult to evaluate the effect of alcohol. In the present study, an attempt was made to measure objectively the clinical effect of alcohol in angina pectoris. Although no increase in ability to work resulted from this type of therapy and no decrease in the duration of an attack of angina pectoris occurred in the majority of patients, alcohol nevertheless seems capable in some cases of producing a certain type of subjective comfort. This may be of some value in the general management of the patient with angina pectoris. It is doubtful whether such medication has a specific effect on the course or severity of the disease.

CONCLUSIONS

Therapeutic doses of whisky do not measurably shorten the duration of attacks of angina pectoris or increase the capacity of the patient with angina for work.

decreased the severity of attacks if taken when pain was coming on, in recent years this effect had not been obtained. All 5 patients used nitroglycerin as the drug of choice for the treatment of attacks.

Effect of Single Doses of Alcohol on Ability to Exercise

Of the 21 patients who took 1 ounce of whisky up to ninety minutes before performing the Standardized Exercise-Tolerance Test, 5 were able to do from 18 to 27 per cent more work than was otherwise possible (Table 2). These increases in exercise tolerance occurred thirty, sixty and ninety minutes after the ingestion of whisky by

ardized Exercise-Tolerance Test, 2 (N S and E B) had no attacks of cardiac pain during the week. This result was not associated with any change in exercise tolerance. Five patients felt subjectively better while on regular doses of whisky. One patient (S L) showed a 23 per cent increase in exercise tolerance, another (H B) showed a 33 per cent decrease, and 3 (B K, E B, and S W) showed no change. The eighth and ninth patients of the group (R S and S R) experienced increased frequency and severity of angina, and 1 patient (R S) was forced to discontinue the medication after several days because of ten to twenty attacks of

*50 per cent alcohol used in place of whisky

†No cardiac pain. Exercise stopped because of fatigue.

one patient (S R), ten, thirty and sixty minutes after taking whisky in another (B K), and between five and fifteen minutes after taking whisky in the remaining 3 (H St, H Sc and H B).

In similar determinations, with 0.3 mg of nitroglycerin taken two minutes before exercise, 4 of these 5 patients were able to do 60 to 75 per cent more work than usual. The fifth patient (B K) could do only 13 per cent more work than usual.

Of the 16 patients who showed no response to alcohol, 3 patients (Group 1) did 60 to 200 per cent more work after nitroglycerin, 5 patients (Group 2) showed 21 to 56 per cent increases after nitroglycerin, and 7 patients (Group 3) did not respond to nitroglycerin.

Effect of Multiple Doses of Alcohol on Ability to Exercise

Of the 9 patients who drank 1 ounce of whisky four times daily for one week, together with a final dose immediately before performing the Stand-

chest pain daily instead of the usual two or three. When whisky was discontinued, the attacks promptly decreased to their usual frequency.

Effect of Alcohol Held in the Mouth on Ability to Exercise

The experience of 1 patient (R S) that touching a drop of whisky to the tongue relieved his anginal attacks was tested in this patient and 7 others. No patient showed an increase in ability to work or a change in the nature of anginal pain when exercising with ½ ounce of whisky held in the mouth.

DISCUSSION

According to the literature, alcohol may affect the patient with angina pectoris by a reflex or vasodilator mechanism or through the central nervous system.

Reflex Mechanism

Almost all attacks of angina pectoris are of less than three minutes' duration.⁸ Since a significant

ture and should establish diagnosis before serious shock results

The treatment must be dictated by the circumstances of the case. Transfusions, operation for ligation of the vessel if bleeding seems to be continuing, the giving of blood coagulants, tight compression and, if necessary, termination of pregnancy are indicated. Termination by cesarean section must be seriously considered if the patient is at term, with a live baby, and not in labor. Since labor strain in itself has been a cause of hematoma, it seems unwise to subject a patient to operation for ligation of the bleeding vessel and within hours or a few days to have her undergo labor, with its additional strain on a damaged rectus abdominis muscle and potential resumption of bleeding. In a multipara not at term, operation for ligation of the bleeding vessel may be sufficient.

If active bleeding has ceased, emptying of the hematoma is neither necessary nor wise, since removal of the clot decreases the pressure on the bleeder and may reactivate the bleeding. Prevention of breakdown and infection may be accomplished by the use of regional and systemic penicillin therapy. If hemorrhage is still in progress, ligation of the offending vessel must be attempted.

CASE REPORT

M. H., a 36-year-old, married tripara, began her last regular period on February 13, 1945, and the expected date of the confinement was November 20. The two previous pregnancies had been successfully terminated by low-forceps deliveries of living normal babies. The past history was negative. There had been no operations.

The prenatal period followed an even, uneventful course. The blood pressure vacillated between 118/62 and 126/70. The urine was consistently normal, and there were no signs or symptoms of toxicity. In the 3rd month, the red-cell count was 4,250,000, the hemoglobin 82 per cent, and the white-cell count 8200. A blood Hinton test was negative. The blood was of Type A and was Rh+. Quickening was noted in the 4th month, and fetal activity continued throughout the pregnancy.

One week before term, the patient had an acute upper respiratory infection with an associated tracheobronchitis. On November 23, a complaint of severe left-sided abdominal pain, associated with nausea and vomiting of 3 hours' duration, was made by telephone. Examination at the patient's home revealed a woman in moderate distress, walking about and holding on to the left side of the abdomen. The pulse was 78 and of good quality. The temperature was 98.4°F, and the blood pressure 120/68. The skin was moist and of normal color. The abdomen was nontender and revealed a uterus at term. A vertex presented and was lightly engaged. The position was O.L.A., and the fetal heart, heard in the left lower quadrant, was of good quality, with a rate of 132. The fetus seemed of normal size. Adjacent to the left cornu was a small, rounded mass the size of a lemon. It was tender and the tenderness was transmitted to the left lower quadrant. There was no muscle spasm or rebound tenderness. Both flanks and costovertebral angles were negative. There was no vaginal bleeding or discharge. The bowels had been sluggish for the last 24 hours. On the previous day the patient had had severe, sustained spasms of coughing which were so intense that she had not felt like eating. During the night there was left-sided pain and nausea.

Three hours after this examination, the pain became so severe that the patient was admitted to Wyman House Cambridge Hospital, for observation. The temperature was 97.4°F, the pulse 104, and the blood pressure 102/60. The red-cell count was 3,640,000, the hemoglobin 75 per cent,

and the white-cell count 15,400. A catheter urine specimen was negative except for occasional white and red cells. The abdomen revealed a mass along the left side of the uterus. It was firm and rounded at the top and the size of a small grapefruit, and extended indefinitely downward. It was exquisitely tender. There was slight muscle spasm, but no rebound tenderness. Rectal and vaginal examinations were negative. The fetal heart beat was present in the left lower quadrant of the abdomen and was of good quality and rate. Fetal motility was palpable and visible. The skin was somewhat pale. No cyst or fibroid had ever been palpable on previous examinations. A provisional diagnosis of ovarian cyst with a twisted pedicle and hemorrhage was made, and a consultant concurred in it. Cesarean section and exploratory laparotomy were decided on.

Under spinal anesthesia, a midline incision was made through the skin and fat. The anterior fascia appeared normal and was incised. The underlying muscle and posterior fascia were cyanotic and edematous. The peritoneum was slightly blue. When the peritoneum was incised, the abdominal cavity was found to be normal. Palpation of the abdominal wall through the incision revealed a mass that started 2 fingerbreadths below the left costal margin and extended downward. It was round and measured 10 cm in diameter and 5 cm in thickness. This was obviously a large hematoma in the left rectus muscle, with extravasation of blood down through the muscle almost to the crest of the ilium. In view of this and the probable result of labor, which was imminent, being 3 days overdue, it was deemed advisable to terminate the pregnancy by cesarean section. A longitudinal cervical section was performed, and a living female baby was readily extracted. Two grams of sulfanilamide powder was dusted over the uterine incision before the bladder reflex was sutured over. The hematoma was more carefully examined, and it was decided that emptying it would be unwise, since the release of tension might result in resumption of active bleeding. Any attempt to dissect above the hematoma to find the bleeder was likewise considered unwise. To aid in prevention of breakdown and secondary infection of the hematoma, a dose of 100,000 units of penicillin sodium in 5 cc. of normal saline solution was injected into the hematoma by means of a long needle traversing the rectus muscle. The abdomen was closed in layers without drainage or retention sutures. The patient was returned to bed in good condition, and the indwelling Foley catheter was connected to a drainage bottle. Penicillin was injected intramuscularly in doses of 20,000 units every three hours for the next 3 days.

The postoperative course was uneventful. Within 24 hours the hematoma was appreciably smaller, and it continued to decrease in size until at discharge 2 weeks after operation it was barely palpable. The wound healed by first intention. The mother and baby were discharged in good condition.

SUMMARY

Hematoma of the rectus abdominis muscle may occur during pregnancy as the result of coughing.

The diagnosis is often missed because of the lack of awareness of such an entity.

The mortality in reported cases is high but can be made much lower.

Early diagnosis and operation, with cesarean section if the pregnancy is at term, offers the best opportunity for obtaining a live mother and baby.

A typical case, with recovery, is reported.

SPONTANEOUS HEMATOMA OF THE ABDOMINAL WALL IN PREGNANCY

Report of a Case

DAVID ROSE, M.D.*

BOSTON

THE occurrence of spontaneous hematoma of the abdominal wall in pregnancy is relatively rare. Perusal of the literature reveals a complication of 28 cases by Torpin.¹ Thomas² reported an additional case that involved a full-term pregnancy, with a resultant live mother and a dead baby. Cesarean section was performed after the patient had gone into shock. Dawson³ reported the occurrence of hematoma in a full-term pregnancy. Cesarean section was performed and a live baby was delivered. Liggett⁴ reported a case in a sextipara at seven months in which he operated and ligated the ruptured blood vessel. Two months later a live baby was delivered from below. This brings the total of reported cases, exclusive of the present one, to 31.

Spontaneous hematoma is the result of rupture of the main inferior epigastric artery or one of its branches. In the 31 cases in the literature, the left-side and right-side occurrences were about equal in number. Almost all the patients were multiparas of thirty years of age or older. In 18 cases, cough was the causative factor. The cause in the remainder was the strain of labor or extraneous factors. The hematoma occurred at term in 9 cases and in the last trimester of pregnancy in 12.

The most striking feature in the reported cases was the high maternal and fetal mortality. Torpin gave a maternal mortality of 15 per cent. There were no maternal deaths in the other cases, so that

the over-all mortality was 13 per cent. The fetal mortality in Torpin's review was also 15 per cent and the fetal death in Thomas's case makes the over-all mortality 16 per cent.

The percentage of maternal and fetal deaths is sufficiently high to merit serious consideration of this condition as a definite hazard, to be included with the other serious hemorrhages found in the later stages of pregnancy. Early recognition and appropriate treatment will definitely decrease the mortality rate, since almost all the reported deaths resulted from hemorrhage continuing to the point of severe shock.

The diagnosis of hematoma can be easily made if one remembers that such a condition can occur. In the case reported herein, the diagnosis was missed because the possibility of such an occurrence was not entertained. It was this fact, together with the similar mistake in diagnosis that prevailed in most of the other cases, that prompted the writing of this paper. The wider dissemination of knowledge that rupture of a vessel of the abdominal wall, with resultant hematoma, into the rectus abdominis muscle can and does occur during pregnancy will doubtless make for more accurate diagnoses, more efficient treatment and a lessened mortality. The appearance of a tender abdominal tumor that increases in size, with a history of cough, should make one aware of the possible hematoma. Continuing observation, with blood studies, x-ray examination and even diagnostic needling of the tumor, coupled with signs of concealed bleeding, completes the pic-

*Associate surgeon, Cambridge Hospital; senior visiting surgeon, Cahill House, Cambridge City Hospital.

In general, spontaneous variations in blood flow were more frequent the higher the water temperature.

At least five factors influenced the deep-muscle temperature—the water-bath or environmental temperature, the length of the exposure, the rate of blood flow, the body temperature and the local metabolic rate. In water baths below 35°C attainment of a steady deep-muscle temperature required an hour or more, in baths at 13°C, it required about two hours. At bath temperatures above the body temperature, equilibrium was reached within one hour. The steady deep-muscle temperature was 4 or 5° higher than that of a water bath at 13°C, and about 2.5° above baths at 20 to 32°C. The rapid initial fall in baths below 20°C was due to the greatly decreased blood flow. When the water-bath temperature equaled the body temperature, the deep-muscle temperature was about the same. At higher bath temperatures the rise in deep-muscle temperature decreased progressively with each increase in bath temperature, and at bath temperatures of 42.5 and 45°C the deep-muscle temperature was usually 39°C. In some cases, however, the deep-muscle temperature diminished when the bath temperature was raised from 42.5 to 45°C, because of the greatly increased blood flow at the higher temperature. In cold baths, those at 13°C, the sensation of cold lasted for only ten minutes. There was no discomfort, but when the arm was taken out after two hours or more, muscular movements were difficult and slow. There was no generalized shivering. Immersion of the forearm in warm baths caused a small, sharp rise in body temperature as the large volume of blood flowing through the arm was heated, this was followed by a plateau and a fall. The body temperature, however, differed by only about 1°C from that of the arm in the coldest and hottest baths employed. Barcroft and Edholm point out that the increased blood flow through the arm at high temperatures almost certainly involved vessels in the muscles as well as in the skin.

Paralysis of the sympathetic supply of the right arm by novocain, given by the paravertebral route, caused the same increase in blood flow in the right hand as did immersion in water at 43°C.⁵ It thus appeared that inhibition of sympathetic activity could account for full vasodilatation in the hand and that there was no need to assume that the sympathetic nerves running to the hand contain vasodilator fibers. Similar evidence was provided for the absence of vasodilator fibers in the sympathetic nerves running to vessels in the forearm.

Peripheral vasodilatation or vasoconstriction produced by warming or cooling the body caused only minor changes in cardiac output. This was attributed to the buffering capacities of the vasomotor system.⁶

The increase in local circulation rate and augmented capillary pressure increased the rate of

edema formation when venous pressure was maintained, so that there was expected to be an increase in lymphatic drainage. In the presence of some lymphatic blockage, however, low-grade subclinical edema might be produced. Warmth was shown to increase the lymphatic capillary network and lymph formation. These changes occurred particularly at temperatures between 45 and 50°C in experiments on cervical lymph flow. At about 50°C, however, changes in capillary permeability that were not immediately reversible occurred.⁷

Blood. Bazett⁸ has stated that a rising blood temperature particularly affects the dissociation constants of acid radicals of proteins, with the result that proteins combine with base that was previously in the form of sodium or potassium bicarbonate. The carbon dioxide thus freed greatly increases acidity and carbon dioxide tension. An alteration of 10°C (18°F) causes an increase in acidity comparable to the normal difference between arterial and venous blood. It is possible that these changes in acidity and gas tension are of some importance in modifying the reactions of tissues to infection. The activities of leukocytes in phagocytosis are probably also modified, since *in vitro* experiments show maximal velocity at 40°C. Studies by Spangenberg,⁹ however, on the effect of external applications of thermal agents on inflammatory reactions in the rabbit showed no significant changes in the cytologic response.

Metabolism. It is well known that increase in temperature has a definite effect on metabolic changes in any tissue, such that the speed of chemical reactions is increased two or three times with a rise of 10°C. This is of considerable clinical significance when heat is applied to the extremities of patients suffering from obstructive arterial disease. In such cases the increase in the metabolic rate and consequent oxygen consumption produced by local exposure to heat may exceed the possible reflex increase in arterial supply. The net result is a relative diminution in the supply of oxygen as compared to the augmented need subsequent to temperature increases. For studies on the influence of temperature on oxygen consumption, the reader is referred to the review of Field and Hall.³

Nervous system. Local application of heat is known to influence the sympathetic nervous system. Gibbon and Landis¹⁰ have observed that immersing the upper extremities in warm water produces vasodilatation in the lower extremities. External applications are also found to affect the transmission of painful stimuli. Although in some experiments the counterirritation thus produced lessens the recorded potentials in sensory nerves, the complete mechanism of effectiveness is not known. The impression was gained from similar studies by Gammon and Starr¹¹ that intermittent application of heat and cold was more effective than either agent used alone. Other experimental studies

MEDICAL PROGRESS

RESEARCH IN PHYSICAL MEDICINE

ARTHUR L. WATKINS, M.D.*

BOSTON

EVALUATION of any therapeutic agent, including physical therapy, must be gauged by its effect on patients and based on knowledge of physiologic action. Scientific investigation in the field of physical medicine is difficult because of the wide variety of agents employed—massage, therapeutic exercise, water, air, radiations (heat, light and ultraviolet rays), vibrations (mechanical and sound) and electricity in various forms. The conditions treated are often ill defined regarding etiology and pathology, and prescription of physical therapy is consequently often empirical, with hope entertained for symptomatic relief. In spite of these well known shortcomings, there is some background of known biologic effects of such physical agents, based on scientific research, which should be recognized by all physicians who prescribe physical therapy. Since instruction in this subject is largely omitted in medical-school curriculums, it seems worth while to review the scientific basis of physical medicine for the benefit of the practicing physician.

HEAT AND COLD THERAPY

Physiologic Effects of Heat

The external application of heat has been used almost instinctively for centuries by sick and injured men and animals. The present knowledge of the actual effects of heat is based on data obtained rather recently. Heat is received in the form of radiant energy, more or less constantly from exposure to sunlight and occasionally from artificial sources. In considering the action of radiant energy it is customary to classify it in subdivisions according to wave length. Beginning with the shortest wave lengths, there are ultraviolet light (180–390 millimicrons), visible light (390–760 millimicrons), near infrared light (760–1500 millimicrons), intermediate infrared light (1500–3000 millimicrons) and far infrared light, with wave lengths greater than 3000 millimicrons. Since the effect of ultraviolet and visible energy is not primarily thermal, these wave lengths will be considered later.

The infrared, or heat, rays employed for therapeutic purposes are generally divided according to their power to penetrate the skin. Heat from nonluminous sources, such as hot-water bottles, hot packs and hot-water baths, does not penetrate the skin more than 1 millimeter, and heating is

effected only by conduction. Energy from luminous sources of heat, however, such as sunlight and tungsten-filament and carbon-filament lamps, is transmitted through the outer layers of the skin, and some slight depth effects are possible.

The rate at which changes of temperature penetrate the tissues is slow, for heat capacity is high and large quantities of heat have to be transported before the temperature of the tissues is greatly altered. Although the temperature of the tissues can be raised to 37°C (98.6°F) with relative rapidity, beyond this point, through the action of circulatory reflexes, heat is quickly dissipated, provided the circulation is intact.¹

Circulation. An outstanding effect of local exposure to heat is stimulation of the vasomotor reflexes.² When following local exposure to heat the temperature of a part is increased from 18 to 39°C, the number of open capillaries is increased, tissue metabolism is accelerated, and the rate of exchange between blood and tissues is increased. Above this temperature the number of open capillaries is greatly increased, and the rate of blood flow is so rapid that the blood entering the veins simulates arterial blood and contains 91 per cent of its saturated value of oxygen, as compared with the usual value of 70 per cent, provided the circulatory system is not diseased. Local heating therefore produces peripheral vasodilatation, raises capillary blood pressure and through relaxation of capillaries increases the area of capillary wall available for fluid interchange.

Recently Field and Hall³ have reviewed over a hundred articles on the physiologic effects of heat and cold, written in the last three years. A paper of particular clinical interest, by Barcroft and Edholm,⁴ deals with the influence of water-bath temperatures ranging from 13 to 45°C on blood flow and deep-muscle temperature in the human forearm. Flow-time relations were considered with reference to three temperature ranges—13 to 35°C, 37 to 42.5°C and 45°C. At temperatures of 13 to 35°C, the flow remained quite constant after the first fifteen minutes. At 37 to 42.5°C it rose to a maximum in periods that shortened as the external temperature rose. Progressive diminution followed this peak, so that no steady state was attained. Factors possibly contributing to this effect are discussed. At 45°C, the blood flow rose to a maximum in about thirty minutes and remained at this high level or even slightly increased.

*Associate in medicine, Harvard Medical School, chief of physical medicine, Massachusetts General Hospital.

to those observed following the fatal administration of nitrous oxide anesthesia. In some cases sudden death during hyperpyrexia has been caused by extensive hemorrhage into the endocardium of the left ventricle and into the septal wall in the region of the bundle of His.

Experiments have shown that *Neisseria gonorrhoeae* is generally destroyed in six to twenty-seven hours by a temperature of ± 1 to $\pm 1.6^{\circ}\text{C}$. Although in these bacteria may be destroyed by the production of fevers in this range, artificial fevers are generally thought to be effective through improvement with bodily defense rather than through destruction by heat alone.

Clinical applications After many years of clinical and laboratory experiments, safe procedures for the induction of artificial fever have been established. These are described in the standard textbooks of physical medicine. Several methods of heating are satisfactory, since they all are based on the fundamental principle of preventing heat loss by an insulated cabinet and transferring heat by conduction from circulating hot air to the body or by conversion of high-frequency electrical energy by means of short-wave diathermy. It has been emphasized that production of fever by physical means is strictly a hospital procedure, to be carried out only by well trained personnel. Experience has shown that patients should be selected with as much care as are those who are to undergo major surgical operations. The chief usefulness of artificial fever lies in the treatment of gonorrhea, both acute and chronic, and its complications and in that of syphilis. Fever therapy is occasionally valuable for treating intractable bronchial asthma, chorea and undulant fever.

Physiologic Effects of Cold

Great interest in the effects of cold and numerous studies on the subject have followed the pioneer work of Smith and Fay²⁵ in the treatment of cancer with temperatures maintained at levels of 75 to 90°F. Studies at these temperatures have shown that the circulatory rates of blood flow are markedly lessened and blood pressure is decreased.²⁶ Electrocardiograms reveal irregularities and changes in the QRS complex and ST intervals. Blood-chemical changes are minimal. Undifferentiated cell growth, such as occurs in cancer, has been found to require an optimal critical temperature level below which degenerative changes occur, whereas normal cellular tissue is capable of withstanding temperatures between 90 and 95°F or lower. On this basis, patients with inoperable cancer have been given hypothermia, with some temporary good results. Relief of pain has been noted in terminal states of metastatic cancer following hypothermia. Other neurologic changes have included an increase in the deep reflexes in moderately low temperatures and absent reflexes as the temperature approaches

78°F. The pupillary reflexes are also altered, dysarthria has been observed, and there is delayed cerebration, including retrograde amnesia. In schizophrenic patients marked changes in mental status have been seen.²⁷ Although regressive changes in cancerous tissues have been noted, cures have not been obtained.

Short exposures to cold also have definite effects. A cold bath, for example, produces the well known changes in the skin described as "gooseflesh," with diminution of capillary blood flow and obvious pallor. Following this there is a reactive hyperemia, with dilatation of the cutaneous vessels. The effects on the circulation rate vary in different subjects. Respiratory action is increased by short applications of cold and later becomes regular and deep. The metabolic rate is usually elevated from the shivering induced. Locally the metabolism is decreased in areas in which there is vasoconstriction of all surface vessels including arteries, arterioles, capillaries, venules and veins. Alterations in temperature are greater with cold than with heat applied locally, so that cold is often said to penetrate better. One of the most important effects of cold is through its sedative action on the nervous system. Mild applications may be used for relief of pain, and actual refrigeration has been found to be an effective anesthetic agent for surgery.²⁸ Wound healing has not been interfered with in these cases.

LIGHT THERAPY

There is a general belief in the therapeutic value of sunlight. Although it is well known that sunlight is necessary and beneficial for plant life, the analogy that it has widespread therapeutic value for man is lacking in scientific proof. Whereas, strictly speaking, light refers only to the wave lengths that produce visual sensation, it is the usual practice to include the invisible ultraviolet rays in discussions of light therapy. The invisible infrared rays have already been considered under the subject of heat. Knowledge of the effect of sunlight, particularly visible and ultraviolet rays, in relation to disease processes is somewhat scanty, but there is a large body of literature based on physical studies in relation to cellular activity and chemical processes. Effects of ultraviolet radiation and sunlight that are of particular interest in relation to medicine have been recently reviewed by Blum.²⁹

Physical Aspects

Some of the established facts concerning penetration and absorption are of interest and will accordingly be briefly summarized. Transmission is extremely low for wave lengths shorter than 320 millimicrons, the spectral region of ultraviolet radiation that is of biological interest. Such radiation is largely absorbed in the epidermis, principally by protein. Transmission increases progressively

have been made on the influence of thermal agents on gastric and intestinal motor activity. Bisgard and Nye¹² found that heat applied to the abdominal wall inhibited motor activity in the stomach, small bowel and colon. Heat applied directly to the stomach from drinking warm liquids, however, had the exactly opposite effect. The conclusions from these studies were that to inhibit the motor activity in the gastrointestinal tract in the presence of inflammatory lesions, such as appendicitis, hot applications rather than cold are indicated.

Recently the effect of heat on skeletal muscle has also been studied particularly in relation to poliomyelitis. During the acute stages of this disease muscles are found to be abnormally sensitive to passive stretching, as indicated by electromyography^{13, 14}. Heat, particularly in the form of luminous radiation, diminishes this spasm or hyperirritability¹⁵. Other studies have shown that heat influences the relaxation phase of muscle contraction¹⁶ but that strength is not improved by application of hot packs¹⁷.

Temperature sensation. Oppel and Hardy¹⁸ have studied the response of the skin to sunlight, visible light and infrared radiation. The infrared rays are divided into those of wave lengths shorter than 3000 millimicrons, designated as penetrating rays, and those of longer wave lengths, designated as nonpenetrating. These authors studied the stimulating effect on sensation of visible light and of penetrating and nonpenetrating infrared radiation and found that the more penetrating the rays, the less sensitive was the subject to them. The skin-surface temperature was elevated highest by nonpenetrating radiation and least by visible light. Hardy and Oppel¹⁹ found that the smallest rate of radiation that the body is capable of receiving as warmth is 0.00015 gram-calorie per centimeter² per second. This amounts to one nine-millionth of the normal hourly loss of radiation from the body surface. The intensity of stimulus necessary to evoke sensation increases as the area stimulated is decreased, although in all cases the magnitude of the stimulus required decreases as the area exposed decreases. These authors' method of measuring the pain threshold has proved to be of some clinical value in evaluating patients' sensitivity to pain and in judging the effectiveness of analgesic drugs in the alleviation of pain.

Local Application of Heat

Few experimental data are available that will help the physician to determine the accurate and optimum dosage of thermal agents. Some studies²⁰ have been made on changes in skin temperature with different sources of heat at different distances. In general these show that penetrating, infrared radiation is more efficient than the nonpenetrating type or other sources of heat whose transport is largely effected by conduction. It is also known

that effective heating cannot be produced by the usual clinical methods in less than thirty to forty-five minutes. Although some experimental devices for measuring radiant heat have been produced,²¹ dosage is still gauged chiefly by the comfort of the patient, and the duration of treatment is too often determined more by habit and convenience than by knowledge of physiologic effects.

General Application of Heat (Fever Therapy)

Much of the present knowledge concerning the effects of heat has resulted from numerous scientific studies on artificial-fever therapy. Over six hundred articles on this subject have been written, and many scientific facts have been established and recently summarized in reviews²²⁻²⁴.

Physiologic effects. Increases in the pulse and the circulatory rate, resulting in a greater volume output of the heart, are outstanding. The maximal increase of circulation occurs between temperatures of 103 and 104°F. Electrocardiographic changes show decreased conduction time and irregularities. The blood volume and viscosity are little altered provided the intake of fluids is sufficient. If there is severe sweating without replacement of fluids, however, the reduction in blood plasma may be sufficient to produce peripheral vascular collapse. Capillary hemorrhages may occur at levels of pressure rendered abnormally low by decreased capillary resistance.

Absorption of fluid from the intestinal tract is frequently retarded during fever therapy, making intravenous administration of fluids necessary. The red-cell count of the circulating blood is generally unchanged, but following an initial decrease the white-cell count rises to levels ranging from 10,000 to 60,000. This leukocytosis is greater in shorter and less intense sessions of fever. Prolonged fevers at high temperatures have been shown to lead to leukopenia. Toxic changes in the polymorphonuclear leukocytes are frequently noted. Artificial fever may produce thrombocytopenia and a decrease in prothrombin and fibrinogen following hepatic damage, so that coagulation of blood is interfered with, leading to potential or actual hemorrhage.

There is slight alteration in the chemical constitution of the blood, aside from changes in the acid-base equilibrium. Marked alkalosis may occur in fevers characterized by severe dehydration and hyperventilation. If no sodium chloride is administered and sweating is profuse, a diminution of chloride is to be expected. The basal metabolic rate is increased by approximately 7 per cent for each degree of fever induced.

Hemorrhagic encephalitis and hemorrhagic pneumonitis have been noted in some cases in which extreme hyperpyrexia has been induced. Adrenal hemorrhage and destruction have also been observed. Post-mortem findings have been similar

in the permeability of lymphatics, hyperesthesia and chemical changes, including enzyme activity

Pigmentation, or sun tanning, is associated with migration of melanin to the superficial layers of the epidermis. There is probably also some formation of new melanin, particularly by ultraviolet rays of greater wave lengths, which may explain the greater tanning effect of sunlight as compared with mercury-arc sources, which have little of the longer ultraviolet radiation.

The existence of tolerance or immunity to sunburn is well recognized. Although it is generally thought that sun tan explains tolerance to increasing exposure to the sun, recent observations have shown that this is not true. This evidence indicates a thickening of the corneum as the major factor in determining tolerance.

Practical Applications

Quantitative aspects The usual measure of the effect of sunburn on the skin is the degree of erythema developed in response to a given dose of ultraviolet radiation. These effects, however, are subject to considerable uncertainty, owing to the number of variable factors influencing the erythema reaction. These include the transmissibility of the corneum in determining the amount of radiation reaching the living cell. The development of the erythema is known to vary in different persons, and the complex nature of the reaction itself makes measurement extremely difficult. Heating of the skin has been shown to shorten the time of appearance of the erythema but to have little effect on the erythema threshold. Sulfanilamide, on the other hand, lowers the threshold, and probably other drugs have similar effects. The erythema threshold varies considerably among different persons, and in the same persons from time to time and from one skin area to another. There is a widely held belief that there is a close relation between the type of complexion and susceptibility to sunburn, but exceptions to these rules are well known. The erythema threshold remains the best yardstick of dosage for clinical use, in the absence of any measuring device equal or superior to it.

Cancer There is strong evidence of a relation between ultraviolet radiation and human cutaneous cancer. In support of this concept are the facts that cancer of the skin occurs principally on the parts of the body most exposed to sunlight, is more frequent among outdoor than among indoor workers, is greatest in the regions of the earth receiving the greatest radiation and is less frequent in the Negro race than in the white race, and that cancer may be produced in the skin of laboratory animals by exposure to ultraviolet radiation.³¹ The latter has also been shown to induce mutations in certain organisms.

Vitamin D Much of the propaganda concerning the beneficial effects of sunlight and ultraviolet

radiation is based on the only clear-cut beneficial effect known to be produced — namely, the formation of vitamin D and the resultant antirachitic action. It is now well known that vitamin D is formed by the action of ultraviolet rays of wave lengths shorter than approximately 320 millimicrons on 7-dehydrocholesterol or some closely similar precursor steroid compound. The photochemical reaction responsible for this process takes place near the surface of the skin, probably in the corneum. Further discussions of this subject may be found in any standard textbook of medicine or physical medicine.

Photosensitization Minor quantitative and qualitative variations in susceptibility to sunburn are well known. When these deviations are considerable, sensitivity is said to exist and may be induced by the presence of certain photosensitizers in the body. Among substances possessing photodynamic action may be mentioned various dyes and pigments, particularly porphyrin. A complete discussion of these rather rare conditions may be found in Blum's³² book on the subject.

Other effects As knowledge concerning the cutaneous effects of sunlight accumulates, there is less evidence to credit numerous claims of widespread benefit. Wave lengths longer than 320 millimicrons have no specific photochemical effect other than pigment darkening, which extends through about 420 millimicrons. Wave lengths shorter than 320 millimicrons are known to have bactericidal action. Ultraviolet radiations of wave lengths that produce sunburn cause injury to the cells of the cornea and conjunctiva, resulting in a condition characterized by pain, visual disturbances, photophobia with excessive secretion, edema and purulent discharge. Such sunburn of the eye, however, does not confer protection against subsequent exposure. This condition also frequently results from exposure to artificial sources of radiation, particularly welding arcs. The damage to the eye from looking directly into the sun, as during an eclipse, is probably due to heating of the retina by infrared radiation rather than ultraviolet. The high incidence of cataract among glass blowers is also thought to be due to the infrared radiation rather than the ultraviolet.

In considering the systemic effects of sunlight, the solar heat load must be considered. This, of course, varies under different climactic conditions, and the changes produced are the same as those imposed by heat from any source. Circulatory changes are known to result from the heat absorbed. Systemic circulatory changes may also result from sunburn itself, with a lowering of the blood pressure and a slight increase in cardiac output, probably from general peripheral arteriolar dilatation. This may be due to the release of leukotoxine or some similar substance, which causes a generalized lowering of capillary permeability. Ultraviolet radiation

with wave length through the near ultraviolet region and is high throughout the visible spectrum, considerable amounts of visible radiation reaching the corneum and even the subcutaneous tissue. Transmission remains high in the near infrared region, but deep indentations appear in the transmission curve at wave lengths corresponding to maximum absorption by water. At the wavelength limit of sunlight, 3000 millimicrons, penetration is extremely slight. There is considerable disagreement concerning the maximum values for penetration from 700 to 1500 millimicrons. The temperature of the tissues at some depth may be raised appreciably when radiation impinges on the

mined by the kind of molecules present in the environment, as well as by the activated molecule. The effect may be characterized by an action spectrum, meaning that light of certain wave lengths is specifically absorbed and leads to the activation of molecules. Action spectrums may follow absorption spectrums so closely that absorbing compounds can thus be identified.

Exposure of the skin to bright summer sunlight for a half-hour or longer is followed by dilatation of vessels and objective erythema and slight swelling. Following prolonged exposure the edema may be marked, with desquamation and blistering and pain or itching. The erythema fades in a few days

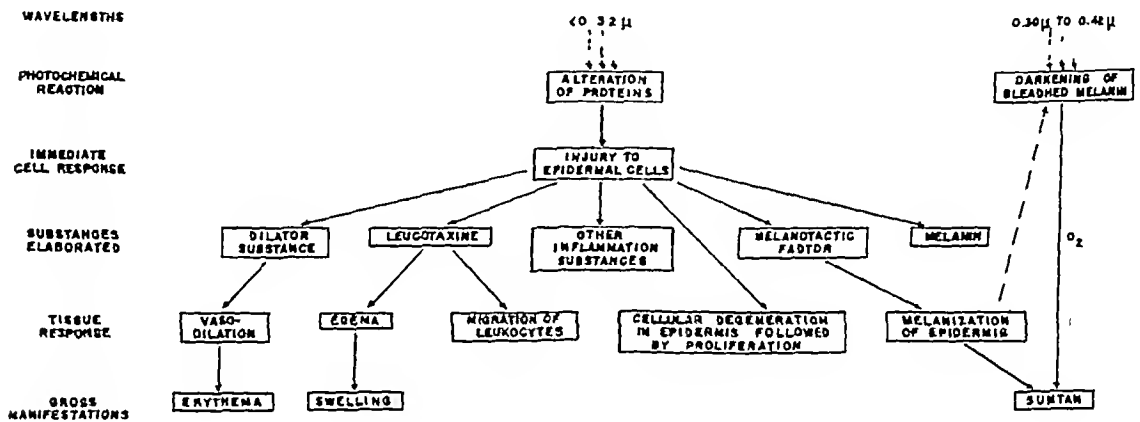

FIGURE 1 Mechanism of Sunburn (Blum²⁹)

skin surface, but this does not indicate actual penetration of the incident radiation. Some of the high values may actually be due to conductive heating. Even if the highest values obtained could be accepted, it is not conceivable that an important fraction of sunlight reaches skin tissues more than a few millimeters beneath the surface. Light of wave lengths that produce the most striking effect in human skin in sunburn penetrates only a small fraction of a millimeter. A large proportion of total sunlight is reflected by human skin, the percentage varying with different complexions. There is no reflection of wave lengths longer than those found in sunlight, the total radiation being absorbed extremely superficially. The human body itself emits a broad band of wave lengths, with a maximum at about 10 microns. In this spectral region human skin behaves as a perfect radiator or black body.

Physiologic Effects

The specific effects of sunlight, particularly ultraviolet radiation, are initiated by a photochemical reaction, as contrasted with the radiant heat effects that result from a local rise in temperature. The photochemical reaction is dependent on activation of molecules by the capture of quanta of radiation. The type of chemical reaction that follows is deter-

mined by the kind of molecules present in the environment, as well as by the activated molecule. The effect may be characterized by an action spectrum, meaning that light of certain wave lengths is specifically absorbed and leads to the activation of molecules. Action spectrums may follow absorption spectrums so closely that absorbing compounds can thus be identified.

Exposure of the skin to bright summer sunlight for a half-hour or longer is followed by dilatation of vessels and objective erythema and slight swelling. Following prolonged exposure the edema may be marked, with desquamation and blistering and pain or itching. The erythema fades in a few days

and is replaced by pigmentation, with an increase of melanin in the epidermis. Blum²⁹ has postulated that sunburn is due to direct injury to the cells of the epidermis by ultraviolet radiation, and that as a result of injury the cells elaborate various substances that bring about specific physiologic responses. These substances are elaborated at slow rates, thus accounting for the long latent period between exposure and the appearance of erythema. A scheme illustrating the sequence of events in sunburn is shown in Figure 1.

Ultraviolet radiation is known to produce injurious effects in living systems in general. Special studies have been made of the effects of ultraviolet radiation on single cells, such as bacteria, protozoa, sperm and eggs. Action spectrums indicate that ultraviolet radiation exerts an injurious action by altering either protein or nucleic acid. The erythema of sunburn is generally credited to the action of a histaminelike dilator substance released by the injured cells, the exact chemical nature of which is unknown. The increased capillary permeability may be due to a substance called by Menkin,³⁰ "leucotaxine," which brings forth migration of leukocytes and tissue edema. Other changes in sunburned skin include an increase in surface temperature, changes in electrical potentials, an increase

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Stated Meeting, February 6, 1946

A STATED meeting of the Council of the Massachusetts Medical Society was held on Wednesday, February 6, 1946, at 10 30 a m, in John Ware Hall, 8 Fenway, Boston. The meeting was called to order by the president, Dr Reginald Fitz, Suffolk. Dr Michael A Tighe, Middlesex North, served as secretary, 152 councilors (Appendix No 1) were present.

The President read the following obituaries

TIMMINS Dr Edward F Timmins died on December 11, 1945. He was sixty-four years old at the time of his death. He was a native of Boston and was educated in medicine at the Harvard Medical School, graduating *cum laude* in 1904. He soon entered practice in South Boston, where he became a well known physician.

From earliest days he was a man of studious habits. In later life he demonstrated astonishing intellectual versatility: he was a poet and an authority in American, English and Irish history, he had discriminating taste in music, he knew ornithology, and he was a well known art critic. Thus he was continuously interested in various extraprofessional affairs: an eminent member of the Audubon Society, the Bostonian Society, the Charitable Irish Society and other nonmedical organizations.

In medicine he proved a devoted public servant, serving for many years as medical inspector of the South Boston district and supervising physician for the Boston School Department.

He was a member of the American Medical Association and of the South Boston Medical Club, of which he had been president. He became a fellow of the Massachusetts Medical Society in 1911, he first served as councilor in 1936, he was appointed to the Committee to Study the Practice of Medicine by Unregistered Persons, and was elected a censor by his district society in 1944.

His sound judgment, keen memory and adroitness in debate and, above all, his loyalty to the traditions of the Society frequently influenced the Council to proper action.

Dr Timmins is survived by his widow, two sons and two daughters.

McNAMARA. Dr John J McNamara died on January 3, 1946. He was seventy-five years old at the time of his death. He was a New Yorker by birth but was adopted by Massachusetts more than sixty years ago. He received his medical education at Tufts College Medical School, obtaining his medical degree in 1900. From his early days he was a man of singular industry and alertness, an athlete-scholar who played both baseball and football for his college as a medical student and at the same time served as an assistant in the Department of Chemistry.

He entered practice in Brockton. As a practitioner his interest in sportsmanship continued for many years, and his appearance at the Brockton Fair, driving in a sulky behind a trotting horse, came to be looked on as one of the Fair's important annual features. He was always a genuine patriot, in 1912 he was appointed by Governor Foss as associate medical examiner, during World War I he served as captain in the Medical Corps of the Army, and more recently he had been physician for the Veterans Bureau.

He was a member of the American Medical Association, the Massachusetts Examining Physicians Association and the Plymouth District Medical Society, of which he had been president. He became a fellow of the Massachusetts Medical Society in 1903, he first served as councilor in 1927, he was a supervising censor during 1933-1937, and he was elected to the Committee on Legislation by his district society in 1943. His wide acquaintance and great

popularity, combined with his wisdom, made his work here particularly valuable.

Dr McNamara is survived by two brothers and a sister.

WOODWARD Dr Samuel B Woodward died on January 29, 1946. He was in his ninety-third year at the time of his death. Born in Worcester, he received his medical education at the Harvard Medical School, where he graduated in 1878. After an internship at the Boston City Hospital and a period of postgraduate study in Europe, he returned to Worcester, where he practiced for forty years. He grew increasingly eminent in his profession and before his retirement from active practice came to occupy high positions on the staffs of the Memorial, St. Vincent's and Worcester City hospitals. As time went on, his activities and responsibilities outside of medicine grew to be unusually varied: he became a trustee of the Worcester Insane Hospital, where his grandfather had been superintendent, he was an incorporator of the Worcester County Institution for Savings and later its president, he was an officer of the Antiquarian Society, he became a director of several banks and industries, he served as chairman of the Citizens' Planning Committee of Worcester. All in all, he had a rare talent for inspiring confidence, and throughout his long career his opinion on a wide range of affairs was earnestly sought by a variety of people with differing interests.

He was a member of the American Medical Association, the Massachusetts Medical Benevolent Society, the Worcester Society for Medical Improvement and the Worcester District Medical Society, of which he had been president. He became a fellow of the Massachusetts Medical Society in 1877, at the end of his third year in medical school, and a councilor in 1902. In 1911 he served on the Committee on Ethics and Discipline. In 1913 he was appointed to a committee to improve workmen's compensation laws. In 1916 he was elected president of the Society and served for a term of three years, among other contributions, presenting to the Society typewritten copies of the Council records from 1781 to 1823 and of the Charter Books—a gift of great importance not only to the Society but to all medical historians. During these years, he also served as chairman of the Committee on State and National Legislation, arguing valiantly for appropriate vaccination laws to prevent outbreaks of smallpox. After having served as president, he acted for two years as chairman of the Committee on Membership and Finance. In 1920, he was instrumental in introducing House Bill 1124, which became law in 1921, thus authorized the Society to engage in publishing a journal to be devoted mainly to medical and surgical science—an act for which readers of the *New England Journal of Medicine* must forever be grateful. In 1921, he read, at the annual meeting, his most distinguished medical paper, "Legislative Aspects of Vaccination." This continues to be a model of medical information.

Before the Stated Meeting of the Council was called to order by President Phippen in February, 1941, Dr Woodward signed the attendance book for the last time. Until his death, he continued to be interested in the Society's welfare, having been steadfastly devoted to it without interruption for sixty-nine years.

Dr Woodward was the last of his family.

At the request of the President the Council stood for one minute in silent tribute to the memory of these former councilors.

The President in referring to a silver pitcher, which was on display on the rostrum, spoke as follows:

In 1881, sixty-five years ago, Dr Benjamin Cotting, a former President, presented the Council with this silver

is said to produce a slight increase in red-cell, white-cell and platelet counts, although reports in this regard are not uniform. Light effects on basal metabolism have been reported, but the only clear-cut effect is that resulting from production of vitamin D, which affects the calcium phosphorus metabolism. No effects on growth can be ascribed to sunlight other than those exerted by vitamin D.

The curative effects of sunlight are repeatedly described and are usually attributed to ultraviolet radiation, presumably of wave lengths shorter than 320 millimicrons. Although rickets can be cured by either sunlight or artificial sources of ultraviolet radiation of wave lengths shorter than 320 millimicrons, other definite therapeutic values are not well substantiated. Some exception to this statement, however, may be found in the successful reports of Finsen's treatment of lupus vulgaris with sunlight and artificial ultraviolet radiation. The effect of the latter in prevention of the common cold is of considerable general interest. The reports of different investigators, however, show different results. Maughan and Smiley³³ reported a 40 per cent reduction of colds in exposed subjects as compared with controls. Other observers, however, found extremely slight differences between exposed and controlled groups. Colebrook's³⁴ studies suggest that the curative effects are similar to those produced by placebos.

The use of ultraviolet radiation in the treatment of a number of dermatologic and medical conditions has previously been described in this series of reports³⁵ and is summarized in the *Handbook of Physical Medicine* published by the American Medical Association in 1945. These conclusions are largely based on clinical observation and are subject to more intense study and research.

Shorter wave lengths of ultraviolet radiation are beginning to be used more extensively to sterilize the air in operating rooms and to prevent spread of infection in hospital rooms, schools and similar places. This aspect of ultraviolet radiation goes beyond the scope of this paper.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Stated Meeting, February 6, 1946

A STATED meeting of the Council of the Massachusetts Medical Society was held on Wednesday, February 6, 1946, at 10 30 a m, in John Ware Hall, 8 Fenway, Boston. The meeting was called to order by the president, Dr Reginald Fitz, Suffolk. Dr Michael A Tighe, Middlesex North, served as secretary, 152 councilors (Appendix No 1) were present.

The President read the following obituaries

TIMMINS. Dr Edward F Timmins died on December 11, 1945. He was sixty-four years old at the time of his death. He was a native of Boston and was educated in medicine at the Harvard Medical School, graduating *cum laude* in 1904. He soon entered practice in South Boston, where he became a well known physician.

From earliest days he was a man of studious habits. In later life he demonstrated astonishing intellectual versatility: he was a poet and an authority in American, English and Irish history, he had discriminating taste in music, he knew ornithology, and he was a well known art critic. Thus he was continuously interested in various extraprofessional affairs: an eminent member of the Audubon Society, the Bostonian Society, the Chantable Irish Society and other nonmedical organizations.

In medicine he proved a devoted public servant, serving for many years as medical inspector of the South Boston district and supervising physician for the Boston School Department.

He was a member of the American Medical Association and of the South Boston Medical Club, of which he had been president. He became a fellow of the Massachusetts Medical Society in 1911, he first served as councilor in 1936, he was appointed to the Committee to Study the Practice of Medicine by Unregistered Persons, and was elected a censor by his district society in 1944.

His sound judgment, keen memory and adroitness in debate and, above all, his loyalty to the traditions of the Society frequently influenced the Council to proper action.

Dr Timmins is survived by his widow, two sons and two daughters.

McNAMARA. Dr John J McNamara died on January 3, 1946. He was seventy-five years old at the time of his death. He was a New Yorker by birth but was adopted by Massachusetts more than sixty years ago. He received his medical education at Tufts College Medical School, obtaining his medical degree in 1900. From his early days he was a man of singular industry and alertness, an athlete-scholar who played both baseball and football for his college as a medical student and at the same time served as an assistant in the Department of Chemistry.

He entered practice in Brockton. As a practitioner his interest in sportsmanship continued for many years, and his appearance at the Brockton Fair, driving in a sulky, behind a trotting horse, came to be looked on as one of the Fair's important annual features. He was always a genuine patriot, in 1912 he was appointed by Governor Foss as associate medical examiner, during World War I he served as captain in the Medical Corps of the Army and more recently he had been physician for the Veterans Bureau.

He was a member of the American Medical Association, the Massachusetts Examining Physicians Association and the Plymouth District Medical Society, of which he had been president. He became a fellow of the Massachusetts Medical Society in 1903, he first served as councilor in 1927, he was a supervising censor during 1933-1937, and he was elected to the Committee on Legislation by his district society in 1943. His wide acquaintance and great

popularity, combined with his wisdom, made his work here particularly valuable.

Dr McNamara is survived by two brothers and a sister.

WOODWARD. Dr Samuel B Woodward died on January 29, 1946. He was in his ninety-third year at the time of his death. Born in Worcester, he received his medical education at the Harvard Medical School, where he graduated in 1878. After an internship at the Boston City Hospital and a period of postgraduate study in Europe, he returned to Worcester, where he practiced for forty years. He grew increasingly eminent in his profession and before his retirement from active practice came to occupy high positions on the staffs of the Memorial, St Vincent's and Worcester City hospitals. mittee meeting said that this arrangement was working well. He added that a committee of physicians from the district society sat in judgment on disputed bills and that its decisions were accepted by all concerned.

The representative for the Norfolk South District Medical Society said that a similar arrangement was in operation in his community and that it even applied to welfare cases that were being treated in hospitals having regular staffs.

The Executive Committee recommends the adoption of this recommendation and such others as are contained in this report.

The Executive Committee reviewed the report of the Committee on Legislation and recommends its acceptance.

The Executive Committee has reviewed the report of the Committee on Cancer. It approved the report and the recommendation contained in it.

The Executive Committee has reviewed the report of the Committee on Medical Defense. As it interprets this report, it contains a recommendation that a committee be set up for the purpose of reviewing the subject of malpractice insurance. The Executive Committee approved this report and the recommendation contained in it.

The Executive Committee reviewed the report of the Committee on Ethics and Discipline and that of the Medical Advisory Committee to the Regional OPA. It approves of both.

The Executive Committee has reviewed the report of the Committee on Public Health. It noted that the chairman of the committee wished to amend the recommendation contained in it so that the Council is now asked to approve the committee's sending a letter, through and at the expense of the American Epilepsy League, Incorporated, to all the physicians in Massachusetts, offering literature on the latest advances in the treatment of epilepsy to those who are interested.

The Executive Committee approves of this change because it believes the original language would involve the Society in a commitment which it should not be asked to assume.

Action on this recommendation will be sought when the report of the Committee on Public Health is formally before the Council.

The Executive Committee reviewed the report of the Committee on Postwar Planning. It approved the report and the recommendations contained in it. It recommends that two additional recommendations be added to this report, namely:

That the Council authorize the President to appoint a special committee for the purpose of initiating plans for a postgraduate assembly in 1946.

That the Council, with the approval of the Committee on Finance, authorize an extraordinary appropriation of one thousand dollars for the use of this committee.

Action on these additional recommendations will be sought when the report of the Committee on Postwar Planning is formally before the Council.

The Executive Committee has reviewed the report of the Military Postgraduate Committee. It approves of this report and, in recommending the adoption of the committee's recommendation that it be discharged, would add the words, "with thanks."

The Executive Committee reviewed the report of the Committee on Council Rules. It approves of the recommendations contained in it.

The Executive Committee reports that a motion recommending that the Council set the membership dues at \$20.00 per year beginning in 1947 was laid on the table until the next meeting of the committee.

The Secretary moved the adoption of the report as a whole. This motion was seconded by Dr. Carl Bearse, Norfolk, and it was so ordered by vote of the Council.

Committee on Finance — Dr. Francis C. Hall, Suffolk, chairman.

This report (Appendix No. 2) was submitted by the chairman. He moved the adoption of the report

and the budget submitted. This motion was seconded by Dr. Peirce H. Leavitt, Plymouth.

The President, in commenting on the budget, said that it represented the largest ever submitted.

Dr. Hall's motion was adopted by vote of the Council.

Committee on Public Relations — Dr. Albert A. Hornor, Suffolk, secretary.

This report (Appendix No. 3) was submitted by the secretary of the committee who moved its acceptance. This motion was seconded by Dr. Roy J. Heffernan, Norfolk.

Dr. Cheever asked whether or not the term "community hospitals" as used in the report meant tax-supported hospitals. Dr. Hornor replied that they referred to any hospital serving a community whether tax-supported or otherwise.

The motion to accept the report was adopted by vote of the Council.

The President said that the report contained many recommendations. The first requested that the Council adopt a plan whereby certain licensed physicians in Massachusetts, who have graduated from unapproved medical schools, may obtain hospital privileges in certain community hospitals. He added that the plan, to be effective, entails approval by the American College of Surgeons, the American Medical Association and the Massachusetts Hospital Association, as well as that of the Council of the Massachusetts Medical Society.

Dr. Hornor moved that the Council adopt the plan as outlined in the report. This motion was seconded by Dr. H. Quimby Gallupe, Middlesex South. Dr. Gallupe made a strong and effective plea for the adoption of this plan.

Dr. Allen G. Rice, Hampden, asked for a definition of the terms "staff meetings" as they appear in the report. Dr. Hornor said that these terms referred to meetings of the staff as a whole wherein were studied interesting and difficult cases, where deaths were analyzed and the whole professional conduct of the hospital reviewed.

Dr. Rice asked whether or not these terms meant that those covered under this plan would be invited to attend staff meetings where officers were elected and new appointments and promotions were considered. Dr. Gallupe, in replying to this question, said that the functions outlined in Dr. Rice's question represented the duties of an executive committee of the staff rather than that of the staff as a whole and that the terminology used in this report referred to the educational meetings of the staff wherein only the professional activities of the hospital were reviewed.

The plan as outlined was adopted by vote of the Council.

The Secretary moved the adoption of the recommendation of the Executive Committee to the effect that the activation of this plan be through the Committee Appointed to Confer with the Massachusetts

water-pitcher, which he hoped thereafter would always be used at Cotting luncheons. The pitcher had been given him in token of friendship by Dr. George Hayward, secretary of the Society from 1826 to 1832 and president from 1852 to 1855. The growth in size of the Council and the change in character of the luncheons have made it difficult to carry forward Dr. Cotting's wishes in regard to the pitcher. It is in attendance at today's meeting, however, out of deference to his desires.

The Secretary presented the record of the last stated meeting of the Council held on October 3, 1945, as published in the *New England Journal of Medicine*, issue of December 20, 1945. He moved its acceptance. This motion was seconded by Dr. David Cheever, Suffolk, and it was so ordered by vote of the Council.

REPORTS OF COMMITTEES

Executive Committee — Dr. Michael A. Tighe, Middlesex North, secretary.

This report, which was submitted by the Secretary, is as follows:

The report of the Executive Committee of the Council has already been sent to each councilor. This has been done in anticipation of the adoption of a new rule which will make such action mandatory on the part of the Secretary. Under this rule not only will the action of the Executive Committee be reported in advance but likewise there will be presented in advance a résumé of the discussion attending any important subject before the committee.

It is hoped that this may be a means of anticipating and answering many questions, the asking and answering of which consume much of the Council's time.

The Secretary regrets that, owing to circumstances over which he had no control, when the original report of the Executive Committee of the Council was sent out, the résumé of the discussion which attended two important subjects could not be included. These résumés will appear in their proper setting in the report which will now be submitted.

The Executive Committee of the Council reviewed the reports of the Committee on Finance and the budget submitted by the committee for the year 1946. It approves of the budget and of the recommendations contained in this report.

The Executive Committee has reviewed the report of the Committee on Public Relations.

The first recommendation contained in this report has to do with a plan whereby graduates of approved schools who are licensed to practice medicine in Massachusetts may be permitted to care for their patients in approved hospitals and participate in certain other activities of such hospitals. This plan in no way attempts to dictate to any hospital what its policy shall be. It recognizes that, already, certain hospitals have adopted this plan or some modification of it and that others might be encouraged to do likewise. This plan realizes the teaching possibilities which are inherent in all hospitals and the necessity of utilizing these possibilities in the interest of good medical care for all the people of the community.

In the discussion, which attended the subject, it was said that two out of every seven licensed physicians in Massachusetts were graduates of unapproved medical schools, that the medical care of many thousands of Massachusetts citizens was in the hands of such graduates and that many of them are in need of the additional training which may be had by some form of association with a good hospital.

It was further brought out that, at least for the moment, the unapproved schools in Massachusetts have been discontinued. While no one could say what the future holds in this respect, it was the tendency of the committee to regard it as a problem which was closed, leaving finally to be dealt with a backlog of imperfectly trained physicians who needed our help if the people of the Commonwealth were to have the kind of medical care to which they were entitled.

What would be the attitude of the Council on Hospitals and Medical Education of the American Medical Association if the hospitals of this state were to adopt some such plan? Would such hospitals lose their rating as hospitals approved for intern training? These are some of the questions to which the committee directed its discussion.

While it was indicated that, until some such formal plan as outlined was approved by the Massachusetts Medical Society and presented to the Council on Hospitals and Medical Education, no formal action might be expected from this source, it did come out that the plan had been informally discussed with the secretary of the Council on Hospitals and Medical Education of the American Medical Association and that he thought it represented a practical way of cleaning up a bad situation. He also expressed it as his opinion that the Council on Hospitals and Medical Education would not penalize the hospital that adopted it.

The attitude of the American College of Surgeons has not been ascertained but here, too, it is unlikely that the plan would be formally approved, pending its approval by the Massachusetts Medical Society.

It was the opinion of the committee that, while not all would avail themselves of the privileges called for in the plan, many might be expected to do so.

Finally, it was also the opinion of the committee that it was much more desirable for the hospitals to voluntarily adopt some such plan as this rather than run the risk of having their doors forced open by legislative enactment.

The Executive Committee recommends that the Council approve this plan.

In the event that this plan is approved when it is formally before the Council, the Executive Committee recommends that its activation shall be through the Committee Appointed to Confer with the Massachusetts Hospital Association.

The second recommendation contained in this report deals with certain principles which should govern the relation of the United States Veterans Administration, civilian physicians and civilian hospitals in the medical and hospital care of those for whom this administration is responsible.

The Executive Committee took note of the tremendous problem which confronts the Veterans Administration in this regard and the Administration's utter inability to meet the requirements of the law without the active and wholehearted co-operation of the civilian physician and civilian hospital. The Committee on Public Relations, in noting the emergency character of the problem involved, made representations to the President dealing with the necessity of immediate action. In compliance with such representations, the Executive Committee noted that the President appointed a committee of the Society to confer with Major General Paul R. Hawley, Acting Surgeon General of the Veterans Administration.

The Executive Committee approved of this act of the President. It recommended that the Council do likewise.

The Secretary moved the adoption of this recommendation. This motion was seconded by Dr. Albert A. Hornor, Suffolk, and it was so ordered by vote of the Council.

The Secretary continued the report as follows:

The last recommendation contained in the report of the Committee on Public Relations is to the effect that, if at any time the Massachusetts Medical Society recommended that the prevailing rate of fees be reduced for the medical care of tax-supported cases, this action be rescinded.

The discussion attending this subject indicated that in May, 1945, the Executive Committee, acting for the Council, approved of the policy of paying physicians for the care of welfare cases in understaffed hospitals at the rate of \$4.00 for the first visit and \$2.00 for each succeeding visit, not to exceed a total sum of \$150.00. It came out in the discussion that the Franklin District Medical Society had long since arranged for the payment of regular fees in tax-supported cases. The representative of the Franklin District Medical Society present at the com-

Dr Moore moved the adoption of the report as a whole. This motion was seconded by Dr Hall, and it was so ordered by vote of the Council.

Committee on Medical Defense—Dr Arthur W Allen, Suffolk, chairman.

In the absence of Dr Allen, the Secretary submitted the report (Appendix No 6) as published and moved its acceptance. This motion was seconded by Dr Bagnall, and it was so ordered by vote of the Council.

The President said that this report contained two recommendations as follows:

That a special committee of five be appointed by the President to review the matter of malpractice insurance; the report of such a committee to be submitted at the next meeting of the Council.

That the Secretary shall notify Mr Nolan that the proposal to the Society outlined in his letter of November 17, 1945, is under advisement.

The Secretary moved the adoption of these recommendations. This motion was seconded by Dr Bagnall, who spoke of a conversation which he had a year ago with the President of the Pennsylvania State Medical Society about the cost of malpractice insurance in that state. He said that the latter said they had a very happy situation in that state, where the coverage costs as little as \$8.00 per year.

Dr Hornor moved as an amendment to the motion to adopt that the committee appointed under these recommendations be given authority to employ counsel if, in its opinion, such employment is deemed necessary. This amendment was seconded by a councilor.

Dr Bearse said that a previous attorney general of Massachusetts had ruled that group insurance along this line is illegal in Massachusetts.

The motion as amended was adopted by vote of the Council.

The Secretary moved the adoption of the report as a whole as amended. This motion was seconded by Dr John B Hall, and it was so ordered by vote of the Council.

Committee on Ethics and Discipline—Dr Ralph R Stratton, Middlesex East, chairman.

This report, which is as follows, was offered by the chairman:

The work of the Committee on Ethics and Discipline since the last meeting has been merely one of routine and requires no report at this time.

The following letter was referred by the Council to the Committee on Ethics and Discipline:

Reginald Fitz, M.D.
319 Longwood Avenue
Boston, Massachusetts

Dear Dr Fitz:

We wish to employ at the Newton Hospital a doctor who has only a dental degree. For a number of years he was engaged in the practice of oral surgery in Boston, retiring before the war. Since Pearl Harbor he has put in a little over a year as a volunteer anesthetist and has carried out that work very efficiently and has met the approval of the surgeons with whom he has worked.

Our question is: Is it proper for a man possessing a dental degree to work as an anesthetist in the Newton Hospital under my supervision?

We would appreciate an early answer. Thanking you I am

Sincerely yours,

R. S. Hunt, M.D.
Anesthetist in Chief

October 1, 1945

It was moved by Dr Rice and seconded by Dr Gardner that, because of the shortness of trained anesthetists and because of the present emergency, it is not unethical to employ the dentist mentioned in the communication provided his work is supervised by Dr Hunt. It was so ordered by vote of the committee.

Dr Stratton moved the acceptance of the report. This motion was seconded by Dr Charles E. Mongan, Middlesex South, and it was so ordered by vote of the Council.

Dr Stratton said the Committee on Ethics and Discipline received a letter, addressed to the President, from Dr R. S. Hunt, of the Newton Hospital. This letter, he added, was reproduced in the committee's report, as was the action of the committee with regard to it. He moved that the Council approve of this action of the committee. This motion was seconded by Dr Bearse, and it was so ordered by vote of the committee.

Dr Stratton moved the adoption of the report as a whole. This motion was seconded by Dr Leavitt, and it was so ordered by vote of the Council.

Medical Advisory Committee to Regional OPA—Dr Joseph Garland, Suffolk, chairman.

This report, which is as follows, was offered by the chairman:

This committee held its latest and perhaps its last full meeting on September 20, 1945. At that time, so soon after the war's ending, processed food had already gone off rationing and rationing had been relaxed on red-point foods. Applications, however, continued to come in, particularly for extra sugar.

On November 23 the day after Thanksgiving, rationing was finally abandoned on all foods except sugar. Sugar will remain scarce until the Philippine crop is available, and will probably continue to be rationed, according to our advices, until April, 1946. Until then, this committee will need to function to some degree. The present allotment of sugar is one-fourth pound weekly per individual.

It apparently seems unfortunate to certain people that privations must continue to exist in the postwar world but we believe that they can be guaranteed against any unusual health hazard even if their requests for extra sugar are ordinarily denied.

This report is offered for the information of the Council.

Dr Garland moved the acceptance of this report. This motion was seconded by Dr John B Hall, and it was so ordered by vote of the Council.

Dr Stratton moved the adoption of the report. This motion was seconded by Dr Felton, and it was so ordered by vote of the Council.

Committee on Public Health—Dr Roy J Ward, Worcester, chairman.

This report (Appendix No 7) was offered by the chairman, who moved its acceptance subject to the recommendation of the Executive Committee. This motion was seconded by Dr Bagnall, and it was so ordered by vote of the Council.

Dr Ward moved the adoption of the report subject to the amendment recommended by the Executive Committee. This motion was seconded by Dr Bagnall. This recommendation is to the effect that the Council approve the Committee on Public Health sending a letter, through and at the expense of the American Epileptic League, Incorporated, to

Hospital Association Dr Hornor seconded this motion, and it was so ordered by vote of the Council

The President said that the second recommendation contained in the report of the Committee on Public Relations was to the effect that the Council affirm its belief, in answer to the Honorable Philip J. Philbin, that the most satisfactory and economical care of veterans in Massachusetts can be obtained by granting them right to free choice of licensed physicians, at prevailing rates in their own communities, and, if hospitalization is required, in local licensed hospitals of their own choice, and that each district society be advised to appoint a special committee authorized to meet on call by the Veterans' Bureau to adjust any disputes or difficulties that might arise under such a program

Dr Hornor moved the adoption of this recommendation This motion was seconded by Dr Charles J. Kickham, Norfolk, and it was so ordered by vote of the Council

The President outlined the third recommendation contained in this report as follows

That each district society shall be advised to appoint a special committee to act in an advisory capacity with local boards of public welfare so that recipients of Old Age Assistance may have free choice of physicians and so that physicians so employed may be properly paid for their services

Dr Hornor moved the adoption of this recommendation

In seconding this motion Dr John J. Dumphy, Worcester, said that there is a new provision in the law which requires that welfare recipients be allowed free choice of physician He said that the Commissioner of Public Welfare in Boston took the initiative in this matter and sought a meeting with the Subcommittee on Tax-Supported Medical Care and that this committee had turned the problem, as it related to Boston, over to the Suffolk District Medical Society

He added that the commissioners of public welfare in other communities might not take this same initiative and that he believed other districts should be urged through the instrumentality of the provision of this recommendation to seek out their respective commissioners, so that this provision of the law might be fully realized

The motion was adopted by vote of the Council

The President outlined the fourth and final recommendation of the Committee on Public Relations as follows

That if, at any time, the Council of the Massachusetts Medical Society recommended that the prevailing rate of fees be reduced for the medical care of tax-supported care, this action be rescinded

Dr Hornor moved the adoption of the recommendation This motion was seconded by a councilor

Dr Dumphy urged the rejection of the recommendation He said that it had never been con-

sidered by the Subcommittee on Tax-Supported Medical Care that its adoption would put the whole profession in an undesirable light before the public

Dr Elmer S. Bagnall, Essex North, said he supported this recommendation in principle but not in practice He thought its adoption at this time might precipitate great difficulties He thought the matter involved would be better handled on a local level and that while the recommendation did not make it mandatory that local groups insist on full fees for the care of the cases involved, he thought it unwise to adopt the recommendation at this time

Dr Leroy E. Parkins, Suffolk, amended the motion to adopt so as to provide for the deletion of the word "rescinded" as it appears at the end of the recommendation and the substitution of the words "reviewed by the Subcommittee on Tax-Supported Medical Care" This amendment was seconded by Dr Bagnall

Dr Hornor said that this matter had been discussed fully in the Committee on Public Relations and that it came out that certain districts were acting on the basis of full fees for tax-supported medical care, that this seemed to be in conflict with a former vote of the Council of the Massachusetts Medical Society and that the recommendation was brought in for the purpose of removing the conflict

The motion as amended was adopted by vote of the Council

Dr Hornor moved the adoption of the report as a whole, as amended This motion was seconded by Dr Cheever, and it was so ordered by vote of the Council

Committee on Legislation — Dr Reginald Fitz, Suffolk, acting chairman

The President said that this report (Appendix No 4) was informational only

Dr Bearse moved its adoption This motion was seconded by Dr James P. O'Hare, Suffolk It was so ordered by vote of the committee

Committee on Cancer — Dr George A. Moore, Plymouth, chairman

This report (Appendix No 5) was presented by the chairman, who moved the acceptance of the report as printed This motion was seconded by Dr John B. Hall, Norfolk It was so ordered by vote of the Council

The President said the report contained one recommendation, which was to the effect that the Council endorse, in principle, instruction about the disease cancer in the public schools of Massachusetts

Dr Moore moved the adoption of the recommendation This motion was seconded by a councilor

Dr Lester M. Felton, Worcester, in registering his opposition to this recommendation, questioned its value The recommendation was adopted by vote of the Council

The first matter considered by the committee had to do with the question of establishing a rule of the Council which would require district councilors to meet and discuss the agenda prior to regular Council meetings. It was voted by the committee not to establish this as a rule but to recommend that the district councilors follow this procedure.

The second matter that was discussed had to do with the report of the Executive Committee. It was believed that this report should contain a resumé of the discussion which took place before the Executive Committee in matters of particular importance. The committee voted to recommend to the Council that a rule providing for such be set up. The committee also voted to recommend to the Council that a further rule be created which would require the Secretary to send to the councilors a week before the Council meeting the report of the Executive Committee.

The Secretary said that these new rules would require the services of a stenographer at the meetings of the Executive Committee. He recommended that the Committee on Council Rules ask the Committee on Finance for an additional appropriation for the Secretary's office of \$150 to cover such costs.

Dr Mongan moved the acceptance of the report. This motion was seconded by Dr Bearse, and it was so ordered by vote of the Council.

The President said that this report, as interpreted by the Executive Committee, contained several recommendations. He stated the first as follows:

That the Secretary shall be directed by the Council to write annually to each district society president, shortly after the latter's election to office, suggesting that the councilors from his district society be asked to meet regularly, prior to Council meetings, to discuss the agenda of each meeting.

Dr Mongan moved the adoption of this recommendation. This motion was seconded by Dr Bagnall, and it was so ordered by vote of the Council.

The second recommendation contained in this report is that two additional rules for its government be adopted by the Council. The first is to be known as Rule 7. This provides that the secretary of the Executive Committee shall prepare a report of each regular meeting of the committee which shall contain an abstract of the discussions and actions of the committee on all matters of particular importance. The second, to be known as Rule 8, provides that the abstract mentioned in Rule 7 be sent to each councilor at least a week before each meeting of the Council.

Dr Mongan moved the adoption of these recommendations. This motion was seconded by Dr Smith, and it was so ordered by vote of the Council.

Dr Fitz said that, with regard to the final recommendation, which called for funds to cover the additional costs made necessary by the adoption of Rules 7 and 8, the Committee on Finance had already acted.

Dr Mongan moved the adoption of the report as a whole. This motion was seconded by Dr Leavitt, and it was so ordered by vote of the committee.

A motion to adopt a report of no report from the following committees was made by Dr Smith and seconded by Dr Felton: Arrangements, Industrial

Health, Medical Education, Nominations, Publications, Society Headquarters, Expert Testimony, To Confer with the Massachusetts Farm Bureau Federation, Maternal Welfare, To Meet with the Massachusetts Hospital Association, To Nominate a Director of Medical Information and Education, To Recommend Blue Shield Directors, Physical Medicine, Postwar Loan Fund and Rehabilitation. The motion was carried by vote of the Council.

The President reminded the Council that, at the stated meeting on October 4, 1944, the Committee on Expert Testimony rendered a report which moved that a standing committee of five or more be appointed by the President, to be called the Committee on Medicolegal Problems and that the by-laws be amended to provide for such a body. The report was received, the President continued, and its motion was warmly debated. The motion was disposed of by being laid on the table. The committee has not reported since that date. The President suggested that action was in order to take this motion from the table so that the Committee on Expert Testimony might feel no restraint in resuming its activities in any manner it deemed proper.

Dr Leavitt moved to take the matter referred to by the President from the table. This motion was seconded by Dr Smith, and it was so ordered by vote of the Council.

APPOINTMENTS BY THE PRESIDENT

Under the provisions of Chapter IV, Section 7, of the by-laws of the Massachusetts Medical Society, and Chapter I, Section 2, of the by-laws of the American Medical Association, the President nominated the following as delegates and alternates to the House of Delegates of the American Medical Association to serve from June 1, 1946 to June 1, 1948:

DELEGATES	ALTERNATES
Charles E. Mongan, Middlesex South	Patrick E. Gear, Hampden
Dwight O'Hara, Middlesex South	William J. Pelleter, Franklin
Walter G. Phippen, Essex South	John I. B. Vail, Barnstable
David D. Scannell, Norfolk	Elmer S. Bagnall, Essex North

There being no nominations from the floor, the Secretary was instructed to cast one ballot confirming the nomination of those named by the President. The Secretary announced that he had complied with this directive, and the President declared the above elected.

The President announced that, under Chapter IV, Section 7, of the by-laws of the Massachusetts Medical Society, he nominated the following councilors to serve as delegates to the annual meetings in 1946 of the other New England state medical societies:

Connecticut: Frederick S. Hopkins, Hampden, Clement F. Kernan, Berkshire.
Maine: Frank R. Ober, Suffolk, Merrill C. Sosman, Suffolk.
New Hampshire: Dwight O'Hara, Middlesex South, Howard F. Root, Suffolk.

all physicians in Massachusetts offering literature on the latest advances in the treatment of epilepsy to those who are interested

The motion was carried by vote of the Council
Committee on Postwar Planning — Dr Howard F Root, Suffolk, chairman

The Secretary offered this report (Appendix No 8) in the absence of Dr Root and moved its acceptance This motion was seconded by Dr Felton, and it was so ordered by vote of the Council

The President said that the report contained three recommendations

The first he outlined as follows

That the Council, in accordance with its previous action, shall inform the Committee on Education and Labor of the United States Senate and other appropriate authorities of its belief that the Federal Government should establish a Department of Health and Welfare with a secretary in the President's Cabinet, under whom will be co-ordinated all important health and welfare programs, exclusive of those of the Army and Navy, the Division of Health being under the direction of a physician

Dr Richard M Smith, Suffolk, moved that the recommendation be tabled This motion was seconded by a councilor, and it was so ordered by vote of the Council

The above action was taken because, during the debate attending this subject, it seemed to many that there were other governmental departments which should be excluded from the provisions of the recommendation and because the Council did not deem itself sufficiently informed at the moment to name such departments

The President outlined the second recommendation as follows

That the Society shall offer its services, through a special committee of five appointed by the President, to the Council on Medical Education and Hospitals of the American Medical Association to assist that council in the provisional approval for internships and residencies of certain Massachusetts hospitals

Dr Felton asked the meaning of the term "certain Massachusetts hospitals" The President replied that it referred to those hospitals that might seek such approval

The Secretary moved the adoption of this recommendation The motion was seconded by a councilor, and it was so ordered by vote of the Council

The President outlined the third recommendation, as amended by the Executive Committee, as follows

That the Council initiate plans for a postgraduate assembly in 1946 through a special committee of five appointed by the President and that an extraordinary appropriation of \$1000 be made for this purpose with the approval of the Committee on Finance

The Secretary moved the adoption of this recommendation This motion was seconded by a councilor

Dr Parkins moved as an amendment "that other state societies of New England be invited to participate as before the war" This amendment was seconded by a councilor

The recommendation as amended was adopted by vote of the Council

Dr W Richard Ohler, Norfolk, moved the adoption of the report as a whole as amended This motion was seconded by Dr Frank R Ober, Suffolk, and it was so ordered by vote of the Council

Military Postgraduate Committee — Dr W Richard Ohler, Norfolk, chairman

The report, which is as follows, was submitted by the chairman

Postgraduate instruction for men in the armed services throughout the country ceased with the close of 1945 In so far as the work of your committee is concerned, the last programs were given in November, 1945

Postgraduate military instruction started in Massachusetts in November, 1942, and was directed by the Military Postgraduate Committee of the Massachusetts Medical Society In the spring of 1943 the American Medical Association, the American College of Physicians and the American College of Surgeons inaugurated a program of postgraduate medical instruction for physicians in the armed services throughout the country By mutual consent and as a result of very pleasant co-operation on the part of all concerned, it was agreed during the summer of 1943 to centralize all the work of providing military postgraduate instruction throughout New England into one committee to be known as the New England Committee for Wartime Graduate Medical Meetings The work of this committee was sponsored by the medical societies of all the New England states together with the American Medical Association, the American College of Physicians and the American College of Surgeons It is to the credit of the Massachusetts Medical Society that this work was started a full year prior to the organization of the national body

Since the fall of 1942, four hundred and twenty-eight postgraduate sessions have been given in twenty three Army, Navy and Coast Guard installations throughout New England There is plenty of evidence indicating that this work has been tremendously appreciated by the armed services It goes without saying that the success of the program in New England results from the unselfish efforts of the many instructors who took part in these programs

It is recommended that the committee be discharged

It is further recommended that a copy of this report be sent to the other New England state medical societies

Dr Ohler moved the acceptance of the report This motion was seconded by Dr Ober, and it was so ordered by vote of the Council

The President pointed out that the report, as amended by the Executive Committee, contained two recommendations

That the committee be discharged with the thanks of the Society

That copies of the report be sent to the military postgraduate committees of the other state medical societies of New England

Dr Smith moved the adoption of the recommendations as amended This motion was seconded by Dr Felton, and it was so ordered by vote of the Council

Dr Ober moved the adoption of the report as a whole as amended This motion was seconded by Dr Ohler, and it was so ordered by vote of the Council

Committee on Council Rules — Dr Charles E Monagan, Middlesex South, chairman

The report, which is as follows, was offered by the chairman

which Dr Baty intended to offer might be all right but that he for one could not conscientiously vote on it without more information than had been submitted

Dr Baty said that, although the survey was going to be made whether the Council approved of it or not, it would help greatly if it had the approval of the established medical organization in Massachusetts

Dr Smith said that the pediatricians felt that there had been a good deal of intrusion by governments in pediatric practice and that justification for this intrusion was based on certain statements which might be true or might not be true. He added that it was the purpose of the Academy, in making this survey, to ascertain the true facts. He thought it desirable that the Council should give its blessing to such an undertaking

Dr Bagnall urged the suspension of the rules because it should not be said of the Council that it would not co-operate in fact finding

Dr William E. Browne, Suffolk, asked Dr Baty if he knew of this matter of the survey before the last Executive Committee meeting. Dr Baty replied that he did not. He added that it was within three days that he had been appointed Massachusetts chairman

Dr Browne asked Dr Baty if he believed that this fact finding could be completed quickly enough to be a factor affecting the deliberations of the senate with regard to Senate Bill 1318

Dr Baty said that such a survey had been completed in North Carolina in six weeks and that, although the actual analysis of the data accumulated could undoubtedly take a longer time, there would be certain factual determinations which could be used much earlier

Dr McCarthy registered his opposition to suspending the rules

By a standing vote the Council voted to suspend the rules and give immediate consideration to the subject of Dr Baty's communication

Dr Baty moved that the Council of the Massachusetts Medical Society approve of the survey of the Children's Health Services which is being undertaken by the American Academy of Pediatrics. This motion was seconded by Dr Felton

Dr Norman A. Welch, Norfolk, asked for a brief explanation of just what the survey consists of and how extensive it is intended to be

Dr Baty replied as follows

The way the survey worked in North Carolina, and the way we hope that it will work here, is that a full-time paid executive was appointed to cover the study. He and the state chairman of the Academy of Pediatrics worked in conjunction, first, with the pediatricians in the state who are members of the Academy. They attempted to obtain information concerning pediatric practice, the number of children seen by physicians and so forth

The thing we are trying to find out first is how much hospitals are doing. We are attempting to collaborate our hospital survey with the one that is being carried on

nationally at the moment, and for that reason in some states we are already beginning to collect data by utilizing the findings of the regular hospital survey

We then want to find out how much in the way of care of children both pediatricians and family physicians or general practitioners are doing, as well as the number of children being seen in clinics, and what type of service is being rendered

We hope to be able to determine in some way the quality of medical care that is being rendered in hospitals, that will be difficult so far as individuals are concerned, but in hospitals we hope that the pediatricians on the staffs, by filling out the forms, will assist us materially. We are drawing up elaborate questionnaires, regarding participation of various individuals, staff meetings and various things that Dr Gallupe mentioned in offering assistance to the graduates of substandard schools. In that way we hope to find out the answers to many of these questions

The way they collected the data about practice in North Carolina was to ask the pediatricians to supply, for a certain period, data concerning the children that they saw in hospitals, in homes and in their offices. We hope to obtain that information from pediatricians, as well as from certain other physicians

We recognize that only a small proportion of medical care to children is rendered by members of the Academy, indeed, the great majority is given by general practitioners

Dr Baty said the Academy was opposed to both Senate Bill 1318 and Senate Bill 1606 and that its suggestions regarding legislation were based almost entirely on the recommendations of the Massachusetts Medical Society

Dr McCarthy asked how this survey was to be financed. Dr Baty replied that he could not answer this exactly but that the total budget would undoubtedly run somewhere around a million dollars. The Academy, he continued, could furnish only a relatively small amount of that sum. Dr John Hubbard was being paid by the Academy a full-time salary, and not a small salary, for his part of the work. The Academy had raised that money out of its own funds, and would raise certain of the other moneys. He added

Some of the funds that are going toward this have been and are being donated by private philanthropic organizations. A great deal of the money will have to be raised locally, and it will be raised in various ways

A good many of the things that we are trying to find out other organizations want to know. At the moment the Council of the Greater Boston Community Fund is very anxious to find out about health services for children among the organizations that they support, and they have appointed a committee and have allotted a budget to carry out this work

The survey was successful in North Carolina, and we believe that it will work here. We are having conferences with various organizations, and we believe that these organizations will help in carrying out certain of the work, that is, that they will supply money. We hope that other types of organizations, such as those assisting crippled children, may, in many states, supply some of this money.

The motion was adopted by vote of the Council

Dr Parkins moved the suspension of the rules so as to permit an informational report concerning the Bureau of Clinical Information (Appendix No 10) to be made part of the record of the meeting. This motion was seconded by Dr Baty, and it was so ordered by vote of the Council

Dr C. J. E. Kickham, Norfolk, asked when the resolution submitted by the Norfolk District Medical

Rhode Island W Richard Ohler, Norfolk, Leroy E
Parkins, Suffolk
Vermont George Ballantyne, Worcester, William A R
Chapin, Hampden

There being no nominations from the floor, the Secretary was instructed to cast one ballot approving the nominations as made by the President. The Secretary announced that he had complied with the directive and the President declared the above elected.

The President nominated Dr H Quimby Galupe, Middlesex South, as delegate for 1946 to the Annual Congress on Medical Education and Licensure of the American Medical Association. This nomination was confirmed by vote of the Council.

The President made the following *ad interim* nominations:

A Price Heusner, Boston, councilor for the Suffolk District, to succeed Edward F Timmins, deceased
Alfred L Duncombe, Brockton, councilor for the Plymouth District, to succeed John J McNamara, deceased
Lewis M Hurxthal, Boston, censor for the Suffolk District, to succeed Edward F Timmins, deceased
Peirce H Leavitt, Brockton, member of the Committee on Legislation representing Plymouth District, to succeed John J McNamara, deceased

The President named Dr Bancroft C Wheeler, Worcester, to the Committee on Finance to succeed Dr Ernest L Hunt, resigned. The President, in making this latter nomination, said that he had accepted Dr Hunt's resignation with very real regret. He described him as a loyal and devoted servant, never self-seeking and always working for the Society's good.

Dr Bagnall moved confirmation of these appointments. This motion was seconded by Dr Hornor, and it was so ordered by vote of the Council.

The President announced the resignation of Mr Manfred Bowditch from the Advisory Committee to the Committee on Industrial Health, this resignation being made necessary by reason of Mr Bowditch's departure from this state. He appointed Dr Harriet L Hardy, Middlesex South, to this vacancy, announcing at the same time that Dr Hardy serves as physician to the Division of Occupational Hygiene in the Department of Labor and Industry.

The President announced his appointment of Dr Humphrey L McCarthy, Norfolk, Dr John J Dumphy, Worcester, and Dr Michael A Tighe, Middlesex North, as a committee to confer with Major General Hawley concerning the medical care of veterans.

He announced that he had appointed Dr Elmer S Bagnall, Essex North, Dr David Cheever, Suffolk, Dr Roger I Lee, Suffolk, Dr Charles E Mongan, Middlesex South, Dr Frank R Ober, Suffolk, Dr Walter G Phippen, Essex South, and Dr George Leonard Schadt, Hampden, as a committee to propose to the Council a director of medical information and education.

He further announced that, in accordance with the vote of the Council, he had appointed the Com-

mittee on Rural Medical Service to Confer with the Massachusetts Farm Bureau Federation as follows: Dr Joseph C Merriam, Middlesex South, *chairman*, John E Moran, Franklin, and Patrick J Sullivan, Berkshire.

He said, in accordance with the action of the Council at its special meeting held on January 9, 1946, he had appointed Dr Elmer S Bagnall, Essex North, principal, and Dr Leland S McKittrick, alternate, to appear before the appropriate committees of the Congress of the United States for the purpose of making known the views of the Massachusetts Medical Society with regard to Senate Bills 1318 and 1606.

Confirmation of these appointments was moved by Dr Leavitt. This motion was seconded by Dr Felton, and it was so ordered by vote of the Council.

NEW BUSINESS

Dr Arthur N Makechnie, Middlesex South, speaking for that district, asked that all the members of the Society be polled by postal card as to whether or not they favored the passage of the Wagner-Murray-Dingell Bill (Senate 1606). He said that such members be asked to answer "yes" or "no" and that they designate whether they are specialists or general practitioners. He expressed it as his opinion that such a poll would show 90 per cent in opposition. This matter was referred to the Committee on Legislation.

The following resolution, signed by Basil E Barton, secretary of the Norfolk District Medical Society, was offered:

As a result of a vote taken by a pre-Council meeting of the Norfolk District Medical Society, held on January 30, 1946, the following resolution was offered:

That it is the sense of the councilors of Norfolk District that a list of the final vote of the Massachusetts legislators on the Chiropractor Bill of 1945 be published in the *New England Journal of Medicine*. This list to be published by districts rather than alphabetically and, if space is difficult to obtain, that it be published in several successive issues, a few districts at a time.

This resolution was referred to the Committee on Legislation.

Dr James M Baty, Massachusetts Chairman of the American Academy of Pediatrics, read a communication (Appendix No 9) addressed to the president, officers and members of the Council of the Massachusetts Medical Society descriptive of a survey which the Academy is conducting as to the medical needs of the children of the United States and the facilities available to meet these needs.

Dr Baty moved that the Council rules be temporarily suspended so that he might ask for the immediate approval of the survey. The motion to suspend the rules was seconded by Dr Smith.

Dr Mongan asked for a restatement of the motion. This Dr Baty did.

Dr Mongan, in opposing the motion, said that all such business should come to the Council by way of the Executive Committee, that the proposition

APPENDIX NO 2

REPORT OF THE COMMITTEE ON FINANCE

The Committee on Finance met on December 12, 1945, at the Headquarters of the Massachusetts Medical Society, 8 Fenway, to discuss the budget of the Society for 1946. Present were Dr Charles F Wilinsky and the chairman of the committee, together with the secretary and the treasurer of the Society, Dr Michael A Tighe, and Dr Eliot Hubbard, Jr. Our report follows.

The Massachusetts Medical Society has come through the war years without a deficit, and indeed with a surplus each year. This has occurred despite lower income from membership dues, and despite the loss of \$4000 of expected profit from our annual meeting in 1945 because this meeting was not held. This surplus has varied in the past seven years from a low of \$4624 in 1938 to a high figure of \$18,835 in 1943. Investments in the General Fund (i.e., reserves) have been increasing, and now have reached the sum of \$167,614 as of December 31, 1944, exclusive of the Building Fund. Our surplus this year is estimated to be \$4042.44. Of this, \$2134.52 represents income from the Building Fund leaving a usable surplus of \$1907.92. (We end this year with a bank balance of \$12,807, December)

The budget of 1946 contains three items which promise to increase our income for 1946, as against 1945. The first item is membership dues. We anticipate \$45,000 from dues in 1946, compared with \$39,000 in 1945. It is possible we shall receive more, as our peak sum from dues has been as high as \$51,000. The second item is the Committee on Arrangements (for the annual meeting). We expect \$4000 from this source. The third item is the *New England Journal of Medicine*. The *Journal* expects to turn over to the Society after December 31, 1945, \$15,000 or more. This item represents a striking change in our budget. Instead of calling for sums of money from the Society varying from \$11,000 per year to lower figures in the past few years, the *Journal* has used none of the \$8000 allowed in our budget for 1945, and expects to turn over to the Society \$15,000 or more. This money can be treated as income for 1946 instead of reserves. The \$5000 allocated to the *Journal* in our budget for 1946 represents an emergency item and it is very unlikely that it will be used. We expect money to come from this source in the future, for the number of subscribers to the *Journal* and the advertising rates have greatly increased. The amount will vary. Expected increase in costs next year make the estimated profit for 1946 only \$6000 instead of the \$19,500 (ten months' operation) or more for 1945. The amount may well be larger.

The expense column of the budget shows some decreases, especially because of the discontinuance of the Committee on Military Postgraduate Teaching. However, the chief characteristic of the expense column is increased expenses. The chief increases lie in greater cost of sending delegates to the A. M. A. Convention, because of its being held in San Francisco, increase in the Secretary's and in administrative expenses, and increased expenses for educational courses for members and for the Bureau of Clinical Information. Not included in the budget is the salary of the projected Director of Information and Education and his expenses—a figure which may represent \$8000 to \$15,000. Without this item, our expenses next year are estimated at \$55,488. Allowing for the expenses of the new director our expense budget may be \$65,000 to \$70,000. Our income without money from the *Journal* is estimated at \$56,161. Should the *Journal* add \$15,000 to our income, we shall have adequate income to pay expenses, with perhaps a little for reserves. If the income from the *Journal* is \$6000 or less, as anticipated, we shall undoubtedly have a deficit in 1947. It is clear that our increasing expenses may soon result in a situation where the Society must decide how we shall raise money to meet them.

PEER P JOHNSON
EDWARD J O'BRIEN
CHARLES F WILINSKY
FRANCIS C HALL, *Chairman*

SUPPLEMENTARY REPORT

Since the meeting of the Committee on Finance and after this report and budget were drawn up, the Committee on

Legislation, through Dr Reginald Fitz, has reported that the number of bills before the Massachusetts Legislature is large and that the Committee on Legislation, therefore, may have unusual expenses.

It is important that sufficient funds be allowed in the budget to be used for legal counsel. We are therefore submitting this request for an additional \$2000 for the Committee on Legislation.

Society would be acted on. The President said that the Committee on Legislation could act on it immediately. Dr. Kickham pointed out that, if the list as called for in the resolution is not published within the next few weeks, its publication will have no point.

The Secretary asked to have referred to the appropriate committee the question of the formation of a woman's auxiliary to the Massachusetts Medical Society, which shall be affiliated with the Woman's Auxiliary of the American Medical Association. The President referred the question to the Committee on Public Relations.

The following letter was read by the Secretary

MASSACHUSETTS HOSPITAL SERVICE, INC.
MASSACHUSETTS MEDICAL SERVICE

January 18, 1946

Dr. Reginald Fitz
319 Longwood Avenue
Boston, Massachusetts

Dear Dr. Fitz:

At a recent meeting in Washington, we attempted to get pay-roll deduction for federal employees. Legislation will be required and a number of government officials suggested that a word of approval from the American Medical Association would be useful. I therefore suggest that appropriate action be taken by the Massachusetts Medical Society recommending approval of the principle of pay-roll deduction for federal employees that they may have Blue Shield and Blue Cross in the usual way. Such action should be transmitted to the American Medical Association to support appropriate action by that group.

I do not see how this can be at all controversial since it is much better to enroll federal employees on a pay roll deduction basis than by the present cumbersome collection basis. I would thank you very much for instituting appropriate action and I trust that it is quite in order.

Sincerely yours,
R. F. CARALANE
Executive Director

This letter was referred to the Committee on Tax-Supported Medical Care of the Committee on Public Relations.

The Secretary read certain letters from Dr. Shields Warren. They were referred to the Committee on Public Relations.

The Secretary read a letter from the Greater Boston Medical Society. This letter was referred to the Subcommittee on Postgraduate Education of the Committee on Postwar Planning.

The Secretary read a letter relative to the observance of Social Hygiene Day. This letter was referred to the Committee on Public Relations.

Dr. Bagnall moved that the Council adjourn. This motion was seconded by Dr. Hornor, and it was so ordered by vote of the Council.

The President announced the Council adjourned at 1:50 p.m.

MICHAEL A. TIGHE, Secretary

APPENDIX NO 3

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations of the Massachusetts Medical Society desires to transmit to the Council of the Massachusetts Medical Society the following items

It is recommended by the Committee on Public Relations that a certain plan suggested by Dr Quimby Gallupe be approved by the Council of the Massachusetts Medical Society. This plan is as follows

For many years the Commonwealth of Massachusetts has registered to practice medicine a number of physicians who have been graduated from unrecognized medical schools. Henceforward, by legislative action, physicians with unapproved educational background no longer will be eligible for registration in Massachusetts. Such physicians who have been registered in the past, however, will continue to practice. They are the doctors of many families in the Commonwealth yet they may not be permitted to care for their patients in our hospitals. Such a situation may prevent patients from receiving as adequate medical care as they have the right to expect from the profession and it tends to encourage the flourishing of inferior hospitals. It is not for the public good. Therefore, the following proposal is presented

Let the trustees and staff of each licensed community hospital in Massachusetts that wishes to do so, be encouraged to invite all registered doctors of medicine in its community to a meeting. At this meeting let the following plan be announced. Henceforward, all such registered physicians in the community are to be invited to attend the hospital's staff meetings, ward rounds, and clinicopathological conferences. The hospital's laboratory and x-ray facilities are to be made available to them. The opinions of the active and consulting staff members are to be made available for consultation. Such physicians are to be invited to send their patients to the hospital under the care of the hospital staff. Their professional behavior is at first to be watched carefully by staff members who may come in contact with them and after a reasonable preliminary period of observation the courtesy privileges of the hospital may be made available to them under some such conditions as the following

At first, as members of the courtesy staff they will be privileged to care for their medical patients under staff guidance. They will not be permitted to do surgery or operative obstetrics until they can demonstrate that they have experienced satisfactory postgraduate training in these specialties or can prove, satisfactorily, their capabilities to the chiefs of these services. Their records will be carefully inspected. Their attendance at staff meetings and other conferences will be recorded. Their relations to their fellows and to their patients will be noted. Their full support of the community effort and their loyalty to the hospital will be expected. Eventually if their work proves satisfactory, they may hope to attain full staff membership.

Such a plan, to operate effectively, requires support of the trustees and the staff of each community hospital wishing to engage in an educational endeavor of this character. These bodies must appreciate that if their communities are to reap benefits from the plan, both trustees and hospital staff must work to perfect its details. The plan should be approved by the American College of Surgeons and the American Medical Association. To succeed, it requires support by the Massachusetts Hospital Association and by the Massachusetts Medical Society.

The Committee on Public Relations recommends that the Council approve this plan and take appropriate measures toward its activation.

REPORT OF SUBCOMMITTEE ON TAX-SUPPORTED MEDICAL CARE

Your committee has received a letter from the Honorable Philip J. Philbin, congressman from the Third Massachusetts District and member of the House Committee on Military Affairs. Herein is stated "I am pleased to say that I believe that veterans ought to be able to receive treatment from doctors of their own choice and in hospitals of their own choice in their own communities as supplementary to their right to clinical and hospital care. I am looking forward to the statement of your committee on these

matters and will gladly join with you in working for more constructive and more effective care and treatment of our beloved veterans."

The Council already has advocated free choice of physicians by veterans for their medical care. Your committee has studied this principle in greater detail. We reaffirm our belief that veterans can obtain most satisfactory and economical medical care by employing licensed physicians of their own choice and of their own communities in whom they have confidence. We believe that veterans requiring hospital care can best be cared for by hospitalization in licensed civilian hospitals of their own choice and particularly in licensed civilian hospitals in their own communities when such hospitals are available. We believe that the costs of home or office visits for veterans and their professional care in hospitals should be paid at the prevailing rates of each community for such services. We believe that the costs of hospitalization for veterans in local licensed civilian hospitals should be met by arrangements for this purpose between each of such said hospitals and the Veterans Administration. We believe that each district society should appoint a committee authorized to meet on call by the Veterans Bureau for the purpose of adjusting any disputes or difficulties that might arise under such a program.

Your committee has received a letter from Major General Paul R. Hawley, acting Surgeon General of the Veterans Administration of the United States of America, requesting that the Massachusetts Medical Society appoint a committee to confer with him about medical care of veterans. This was discussed by all members of the Committee on Public Relations. Dr. Ellison moved and Dr. Sullivan seconded the motion requesting that this committee be appointed immediately by Dr. Fitz because it was an emergency. This motion was carried unanimously. Dr. Fitz then appointed Dr. John J. Dumphy, Dr. Michael A. Tighe and Dr. Humphrey L. McCarthy to serve on such a committee.

The chairman and Dr. Hornor met with Mr. O'Hare, agent of the Board of Public Welfare for the City of Boston, to discuss ways in which the boards of public welfare, particularly that in Boston, could obtain help from the Massachusetts Medical Society. It was brought out that all recipients of old-age assistance are entitled to free choice of physicians and it is incumbent on the local boards of public welfare to see that this practice is followed and that the physicians are properly paid. Our conference with Mr. O'Hare and a later conference with the Commissioner of Public Welfare for the Commonwealth of Massachusetts, Mr. Tomkins, causes us to recommend that each district medical society appoint a committee to act in an advisory capacity with their local boards of public welfare in attaining the ends above mentioned.

The Committee on Public Relations recommends that this report be accepted and the recommendations contained in it be adopted, and that as it relates to the Veterans Administration a copy of it be sent to the Honorable Philip J. Philbin.

The Committee on Public Relations recommends to the Council that if, at any time, the Massachusetts Medical Society has recommended that the prevailing rate of fees be reduced for the care of tax-supported medical cases that this action be rescinded.

ALBERT A. HORNOR, Secretary

APPENDIX NO 4

REPORT OF THE COMMITTEE ON LEGISLATION

Since the last meeting of the Council your committee has been actively engaged through subcommittees in co-operation with subcommittees of the Postwar Planning Committee and of the Committee on Public Relations in drawing an appropriate report on national legislation to be presented to the Council. This report was acted on at the special meeting of the Council held on January 9, 1946.

Your committee has been studying methods for bringing to the district societies a sense of the importance of medical citizenship and realization that only by the active interest on the part of individual doctors can their knowledge and views receive as much consideration as they deserve by any legislative body. It appears difficult to interest the busy practitioner in such matters, yet to accomplish this is extremely important in times when legislation pertaining to public health is becoming increasingly popular.

APPENDIX NO 7

REPORT OF THE COMMITTEE ON PUBLIC HEALTH

The Committee on Public Health has had two meetings, and a subcommittee one meeting. Dr Bagnall of the subcommittee will make a supplementary report on his study concerning legal restrictions of the sale of drugs dangerous to the public health.

President Fitz referred to our committee a letter from the American Epileptic League, Incorporated, asking him to give them a list of physicians in rural areas who are competent to care for epileptics — an increased number of such cases are expected as casualties from our armed forces.

After a discussion of the subject in which we had the advice of Dr William Lennox, it was voted to recommend to the Council that we circulate the profession with a letter concerning the importance of the knowledge of recent advances in the treatment of epilepsy and offering to forward such material as is available on the subject to those interested. Material for this letter is attached. (See below.)

President Fitz also referred to us a communication from a group of school executives, asking for a committee from the Society to formulate plans for the improvement of medical services to the schools.

After discussion of the problem during which we were joined by Dr Florence McKay, it was voted to appoint a subcommittee to study the deficiencies noted and recommend a remedy.

We hope these recommendations will be ready to be presented to the Council in May.

This report has one informational study by Dr Bagnall — a report of progress on a study to improve the medical services to the schools and a recommendation that the Council approve of the committee's sending a letter to all the physicians in Massachusetts offering to send literature on the latest advances in the treatment of epilepsy to those who are interested.

ROY J WARD, Chairman

* * *

Dear Doctors:

The Committee on Public Health of the Massachusetts Medical Society is commissioned by the Society to foster the knowledge of the prevention and treatment of disease by any appropriate measures. Your committee believes that epilepsy is a condition in which definite advances have been made in recent years of which physicians throughout the Commonwealth might be better informed. These advances are of three sorts: first, use of the electroencephalograph for diagnosis and as a guide in treatment; second, the newer drugs, phenytoin (dilantin) sodium for grand mal and psychomotor seizures, and trimethoprim (tridione) for the petit mal triad and third, social aids, looking toward better opportunities for education and employment.

Also looking toward the future, there are plans for the establishment in Boston of a diagnostic-training research center, which might aid doctors in the better handling of their epileptic patients.

The American Epilepsy League (a national lay organization, which has a substantial group of medical advisors and headquarters at 50 State Street, Boston) has offered to supply doctors of the Commonwealth with pertinent information on various aspects of epilepsy. Some articles are reprints from medical journals; others are written for popular consumption.

A list of the items that are at present available is enclosed. Please check those which you would like for yourself or for patients and return in the enclosed envelope. Material will be sent from the office of the League. Even if you are not interested, or see no epileptics, will you assist in the collection of data by answering the questions at the end. Any comments or questions will be welcome.

Sincerely yours,

COMMITTEE ON PUBLIC HEALTH
ERNEST M. MORRIS
GEORGE L. STEELE

APPENDIX NO 8

REPORT OF THE COMMITTEE ON POSTWAR PLANNING

In accordance with the action of the Council on February 2, 1944, the committee recommends that the Council of the Massachusetts Medical Society suggest to the Committee on Education and Labor of the United States Senate and to other appropriate authorities, that the Federal Government establish a department of health and welfare with a secretary in the President's Cabinet under whom would be coordinated all important health and welfare programs exclusive of those of the Army and Navy, and that the Division of Health should be under the direction of a physician.

Consultations with a representative of the Board of Collegiate Authority resulted in a better understanding of the approval of hospitals to provide training for returned veterans. Various meetings have been held with hospital representatives consisting of superintendents and staff members, to consider increasing the opportunities for returning veterans in Massachusetts hospitals. Seventy-six hospitals have listed their needs for interns and residents at Fenway.

The Subcommittee on Hospitals further reported on the conversations that had been held with Dr Johnson, secretary of the American Medical Association's Council on Medical Education and Hospitals on how approval for hospitals for internships and residencies could be expedited. The question was asked how far the Society could assist the Council on Medical Education and Hospitals. Also, Dr Westmoreland reported at the Beth Israel Hospital in Boston on further details relating to approval of hospitals. He reported that the Council on Medical Education and Hospitals of the American Medical Association would appreciate such help under qualified leadership. Dr Fitz, a member of this Council, confirmed that the Council on Medical Education and Hospitals is practically overwhelmed by requests from hospitals for approval all over the United States. Also, he believes that this council of the American Medical Association would appreciate the assistance of a committee from the Massachusetts Medical Society that would help expedite probationary approval of Massachusetts hospitals.

The committee recommends that in view of the postwar emergency, the Council of the Massachusetts Medical Society approve the principle of active co-operation with the Committee on Medical Education and Hospitals of the American Medical Association, and that the Massachusetts Medical Society, through an appropriate committee, offer its services to the Council on Medical Education and Hospitals, to the appraisal for provisional approval of hospitals. It is further recommended that a committee of five be appointed by the president of the Society to co-operate with the Council on Medical Education and Hospitals with this objective.

The work of the Subcommittee on Postgraduate Medical Education, including direction of the Bureau of Clinical Information and the conduct of postgraduate courses, has steadily increased. Up to December 12, two hundred fifty-two service doctors have registered at the Bureau of Clinical Information. During the last three months of this year postgraduate exercises have been held in sixteen towns and places for 1946 provide for twenty-four exercises in each of the six circuits. Actually these twenty-four exercises will include a two-day session during which a team of three or four instructors will teach in three to five different places. In addition, the committee has established tentative programs of bi-weekly postgraduate exercises in Boston. Certain localities in the State have asked for further and more frequently conducted exercises.

Your committee is in the process of studying and digesting as quickly as possible the various bills pertaining to public health and the practice of medicine which will be introduced in the next session of the Great and General Court of Massachusetts.

Dr. Humphrey L. McCarthy, on December 12, 1945, submitted his resignation as chairman of the committee. His resignation was accepted with regret by his fellow members of the committee and by the President. He proved imaginative, energetic and hard working. Fortunately he retains membership on the committee so that his services to the Society are not lost. Sufficient time has not elapsed for a new chairman to be elected, a method of selecting the chairman used by this committee for many years in accordance with *Robert's Rules of Order*. This authority states that any standing committee, by a majority of its number, usually elects a chairman.

This report is submitted as an informational report.

REGINALD FITZ, Acting Chairman

APPENDIX NO 5

REPORT OF THE COMMITTEE ON CANCER

A meeting of the Committee on Cancer was held September 19, 1945. Improvement in diagnostic procedures and methods of educating the laity in the disease, cancer, throughout the Commonwealth, were discussed and would appear to be of interest to the Council.

Vaginal smears for the diagnosis of uterine cancer are now a routine procedure in many of the cancer clinics in all female patients. It is expected that this method of diagnosis will be adopted by all the clinics in the near future.

Cancer symposiums have been sponsored by the cancer clinics in several cities. These were conducted both in the afternoon and evening to afford an opportunity for more to attend. Speakers of recognized ability in cancer therapy and from the various specialties in practice have addressed these gatherings. The large attendance at these symposiums has been very surprising and the requests from the laity for more frequent educational meetings of this type have been most gratifying.

Instruction in cancer in the public schools of Massachusetts in many communities is now a part of the regular curriculum. The value of such instruction both to the school children and to their parents with regard to early recognition and early treatment of the disease is inestimable.

Lynn and Malden have quite elaborate programs of instruction in cancer in the schools. It is hoped that cancer statistics of these communities will be compiled in the future to evaluate the results as compared with other communities with less extensive programs. Instruction in cancer is now a part of the school curriculum in many communities in Montana, North Dakota, Minnesota, Wisconsin, Iowa, Michigan, Pennsylvania, Alabama, Ohio and New York. In some states an outline for school programs is furnished the schools by the state medical society.

The Committee on Cancer is of the opinion that instruction in the disease, cancer, in the public schools is a valuable method of publicity and indorses in principle making such instruction a part of the school curriculum. The method of instruction, we believe, should be determined by the school authorities of the communities.

APPENDIX NO 6

REPORT OF THE COMMITTEE ON MEDICAL DEFENSE

I have your communication from the American Policyholders' Insurance Company regarding writing an over-all group malpractice liability insurance policy for members of the Society. (See below.)

I have sent this letter to the two members of the committee available. Dr. Edwin D. Gardner, of New Bedford, sees no reason why this company should not be seriously considered but does not state definitely that he favors group

malpractice-insurance protection for the entire Society written by one company. The other member, Dr. William R. Morrison, is very distinctly opposed to the plan, saying that he believes our present system of free choice with protection given to the members not insured by our own attorneys is a satisfactory one.

When Dr. Bagnall was president of the Society, he suggested that the plan of protection for medical defense should be studied again and considered on a different basis from our present one. At this time, Dr. Guy Richardson, of Haverhill, had made a considerable study of malpractice insurance as it has affected men in that community particularly, and believed that a better system than the one we now use might be worked out.

I mention all of this because I think probably the time has come when the entire problem should be reviewed. It is perfectly true that the two insurance companies now writing most of the malpractice insurance in this state, although their rates are somewhat different, do an equally good job. I would suppose that the American Policyholders' Insurance Company would like the entire business instead of simply being allowed to write the insurance as the other companies do. It will be remembered that some years ago the company represented by Mr. George Crosbie, which now writes a great deal of the insurance, wanted to have complete control over the malpractice defense of the Society and this was not approved by the Council.

The argument in favor of one insurance company over another is their financial rating, or their ability to pay their obligations in the face of a bad financial period.

I have long felt that the Massachusetts Medical Society might undertake its own insurance plan but I can easily see that this would involve too much difficulty in many ways. It would be comparable to starting the Blue Shield or something of that nature, which, although a great success, required a tremendous amount of work and continued endeavor on the part of many members of the Society.

I think this question might be discussed at the next meeting of the Executive Committee to see whether or not the time has come when the problem of malpractice insurance should be reviewed. I would like very much to be relieved from any responsibility in this matter since I seem to have too many irons in the fire. I would be glad to give my advice to any committee appointed, to the best of my ability, but would prefer not to have to make the study myself.

ARTHUR W. ALLEN, Chairman

AMERICAN POLICYHOLDERS' INSURANCE COMPANY
Home Office Boston, Massachusetts

November 17, 1945

Massachusetts Medical Society
8 Fenway
Boston, Massachusetts

Attention Secretary

Dear Sir:

The American Policyholders' Insurance Company, an American stock insurance company, is desirous of establishing for the Massachusetts Medical Society a group malpractice liability insurance policy for the members of your society who would want to subscribe to it. We would issue a master policy to the Society and individual policies to the members subscribing to it for whatever limits of liability they would desire, of course, only members of the Society in good standing would be eligible under this group arrangement.

We are in a position to offer this protection to your members at an exceptionally low cost. The protection would be all-inclusive and would insure the members of your society for any and all contingencies upon which a claim or suit for malpractice could be based.

If it is possible to discuss this matter in detail with the Executive Committee of your society or with that committee whose function it is to handle matters of this kind for your Society, the writer would be pleased to discuss the matter with them personally at your offices at a time convenient to you, giving the writer sufficient notice so that transportation arrangements might be made.

Very truly yours,

JOHN A. NOLAN
Malpractice Division

APPENDIX NO 9

LETTER FROM DR JAMES M. BATY

February 6, 1946

To the President, Officers and Members of the Council of the Massachusetts Medical Society, Gentlemen:

The American Academy of Pediatrics at its annual meeting in St. Louis in November, 1944, approved a plan to make a survey of the medical needs of the children of the United States and the facilities available to meet these needs.

The organizational work for this survey has been completed. Dr. John Hubbard, of Boston, has accepted the full-time position of director of this work and now has an office at the Children's Hospital in Washington, D. C. The Children's Bureau and the United States Public Health Service are co-operating in making this survey and have assigned full-time workers to assist Dr. Hubbard.

North Carolina was selected as the pilot state for the survey. The work was begun in North Carolina in November, 1945, and has been completed. The data obtained in this state have not been analyzed completely as yet. It is now planned to begin the survey in the individual states throughout the country; it is hoped within six weeks to two months.

The survey is entirely fact-finding in nature and will attempt to determine the nature as well as the amount of health services being rendered to children by physicians, hospitals, clinics, social agencies and other organizations. An executive secretary will be appointed in each state to do the work in co-operation with Dr. Hubbard and the members of the American Academy of Pediatrics and with the assistance of local organizations that are willing to participate.

It is hoped that the results of this survey will be of value to the medical profession in general and to the American Academy of Pediatrics in particular in the formation of sound opinions and constructive criticisms relative to legislation aimed to improve the quality and distribution of medical care.

Respectfully submitted,

JAMES MARVIN BATY, M.D.
State Chairman for Massachusetts
American Academy of Pediatrics

APPENDIX NO 10

SUPPLEMENT TO REPORT OF POSTWAR PLANNING COMMITTEE

A review of the activities of the Bureau of Clinical Information of the Massachusetts Medical Society for the year ending December 1, 1945, shows that the *Bulletin* was distributed to various groups including hospitals, private physicians, medical officers of the Army and Navy and Veteran's Bureau, social-service departments, medical schools and so forth, to a total of 3489. A further analysis shows that the *Bulletin*, while mainly distributed in Massachusetts, was also sent by request to fifteen other states and four foreign countries and Canada. Requests for the *Bulletin* have been received from such agencies as the Massachusetts Department of Education, libraries of medical schools and Army, Navy and veterans' hospitals.

Since August, 1945, there have been 204 requests for data on refresher courses, residencies or locations. During this period and especially in the last several months, the office has been visited in increasing numbers by returning medical officers who wish to get information and to discuss their personal problems. In conjunction with the above activities of the Bureau, the secretary of the Bureau keeps the Bureau of Information of the American Medical Association informed as to changes in address and status of all members of the American Medical Association registered from Massachusetts. This is accomplished by a monthly report. All returning veterans are requested to fill out a form-sheet

giving the data in regard to their military service, present address and other pertinent facts, which is transmitted to the Directory Department of the American Medical Association. Another activity of the Bureau is advice and help in filling out forms in regard to eligibility under the G. I. Bill of Rights and related information of the Veterans Administration. Many requests have been received in regard to the Blue Cross and Blue Shield.

The requests that have come to the Bureau are of many types and varied in their scope, for example, a wife wanted to know where she could obtain extra red points for her anemic husband, there have been requests for lists of convalescent homes, a "good doctor for marriage problems" and a "good doctor for diabetes." A physician called to know the name of a film, and where it could be obtained, that was given at one of the meetings of the Society. There have been requests for information about openings for doctors' secretaries and requests from visiting doctors for information about operations and clinics. Often physicians, while in Boston, keep in touch with the Bureau for help in planning their time so that their stay is of the greatest value. Two physicians from Montreal come to Boston regularly for refresher work and plan their time according to the schedule of the *Bulletin*. A doctor from Calgary, Alberta, comes several times during the year and uses the *Bulletin* for his guide, and gets in touch with the Bureau for extra data. Two real-estate firms have been in touch with the Bureau, and as a consequence one service man found a good office location and home, which was formerly occupied by a doctor. A second home is now in the process of being bought by a serviceman. The servicemen express their gratitude for the *Bulletin*, as it helps them plan their refresher work. They say they could not get along without it. These are some of the ways and means in which the Bureau has been helpful to the servicemen.

An extremely important function of the Bureau, and one that will increase in importance, is the co-ordination of information concerning refresher courses and opportunities for attendance at clinics of the various medical schools, hospitals and private clinics. To promote this, conferences have been held and requests made for submission to the Bureau of Information of such data so that it is available when requests are made by individuals. A plan is under consideration for admission to certain clinics by card in order to prevent overcrowding and interference with small groups. We have in contemplation a plan whereby the hospitals and clinics may submit their clinical facilities under classified headings. Thus an applicant to the Bureau could be told at what hospital and at what time various types of clinics are held, although it must be kept in mind that such clinics are not always open to all physicians.

The above summary, plus a perusal of the detailed report below, shows that the Bureau of Clinical Information of the Massachusetts Medical Society has justified the wisdom of its sponsors. Its activities have grown in diversity each month, as has the quantity of information requested and dispensed. It is a real satisfaction to read the letters of gratitude that have been received from those who have consulted the Bureau. The demand for the Bureau's service has become increasingly widespread, this first year has naturally been one of an experimental nature, but it appears to be an activity that has well justified the effort and expense involved.

This report could not be concluded without a word of commendation to Miss Mary D. Gaston, secretary of the Bureau, who has made every physician and layman who has called feel that there is a personal interest in each and that time and effort expended in his personal problem is the function of the Bureau.

The activities of the Bureau are a part of the functions of the Subcommittee on Postgraduate Medical Education. Dr. Richard Ohler, chairman of the committee, has made excellent progress in organizing the respective areas of the Commonwealth for clinical postgraduate instruction as well as the lecture course for the Metropolitan Boston area, as published in the *Journal*. The Clinical Information Bureau activities are under the direction of Dr. Charles J. Kickham, a member of the Committee on Postgraduate Medical Education. Dr. Kickham has prepared the above information about the Information Bureau.

EDITH E. PARRIS, *Assistant Editor*

CASE 32181

PRESENTATION OF CASE

A forty-eight-year-old machinery salesman entered the hospital after suddenly collapsing on the street.

The patient had been known to be hypertensive for fifteen years, but no record of his blood pressure was available. For four or five years before entry he had been on a reducing diet and had dropped from a maximum of 250 pounds to about 160 pounds. One month before admission he noted for the first time mild dyspnea on moderate exertion. At about the same time he developed a nonproductive cough, which was not relieved by sitting or standing. There was no previous history of headaches, vertigo, tinnitus, orthopnea, precordial distress or ankle edema. On the day of admission he felt well until evening when, while walking against a cold wind, he was suddenly seized with a tight feeling across the anterior chest, just as if his vest were too tight. At the same time he became increasingly weak, and finally his knees buckled under him and he collapsed. His sister brought him to the hospital in a taxicab.

Physical examination revealed a pale, emaciated, anxious, somewhat dyspneic man appearing both acutely and chronically ill. He complained of feeling hot and of having a dry mouth and a tight feeling in the chest. The skin was generally warm and dry, but the hands were cool and moist. When sitting up, the neck veins were distended and pulsating. There were moist, crepitant rales over the bases of both lungs. The left cardiac border was percussed 14 cm. to the left of the midsternal line. The sounds were regular. A Grade II systolic murmur was heard at the apex. The liver was thought to be enlarged. There was moderate pitting edema over the ankles. A right inguinal hernia enlarged to the size of a grapefruit on coughing. The fundi showed flame-shaped hemorrhages and moderate arteriosclerosis with arteriovenous nicking.

The temperature was 100.4°F, the pulse 130, and the respirations 34. The blood pressure was 230 systolic, 150 diastolic.

Examination of the blood showed a hemoglobin of 15 gm. The white-cell count was 13,000, with

84 per cent neutrophils. The nonprotein nitrogen was 52 mg. per 100 cc., the serum protein 5.9 gm. and the cholesterol 203 mg. The urine gave a ++ test for albumin, the sediment contained many hyaline casts. The specific gravity of two specimens was recorded as 1.016 and 1.022, respectively. The vital capacity was 1000 cc.

An x-ray film of the chest showed a cardiac shadow enlarged in all diameters. The lung roots and pulmonary markings were prominent. The costophrenic angles were obliterated by fluid. An electrocardiogram showed sinus tachycardia, at a rate of 150, a normal axis and a PR interval of 0.12 second. T₁ was inverted, T₂ and T₃ were low and upright, ST was elevated, and the T wave was upright in Leads CF₁ and CF₄, with slight inversion in Lead CF₃.

The patient was given morphine, digitalis, Mercururin and ammonium chloride, but this resulted in no diuresis or a lowering of the pulse or respiratory rate. He developed increasing respiratory embarrassment, cyanosis and peripheral edema, and his general status persistently disintegrated.

On the fourth hospital day the heart sounds remained good. The blood pressure was 110 systolic, 90 diastolic, with no variation in respiration. The scleras appeared slightly jaundiced, but a blood specimen taken on the following day showed a van den Bergh of only 1.4 mg. direct and 1.9 mg. total.

On the fifth hospital day, the respirations became Cheyne-Stokes in character and the patient fell into a stupor. He was placed on continuous intranasal oxygen, but in his irrational state he succeeded several times in removing the nasal catheter and climbing out of bed.

On the sixth hospital day respirations gradually ceased.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD F. BLAND. We are concerned with a man in the middle-age group with severe hypertension of long standing. There had occurred a significant decrease in his cardiac reserve for a month and then, without warning, he collapsed on the street, with a feeling of tightness in the chest, which seems a little more than just the discomfort from respiratory distress. Shortly after admission the patient was described as being in considerable distress. He had evidence in his peripheral circulation of venous stasis (distended neck veins), and subsequently the x-ray films showed signs of congestion in the lungs, as well as a big heart. There are one or two things at this point that we should like to know. Nothing is said about a gallop rhythm. Such should have been present, and perhaps a pulsus alternans. We should also like to know about the pulmonic second sound, which is usually accentuated with this degree of pulmonary congestion. He was obviously in a critical condition.

Of the laboratory aids we expect most help from the electrocardiograms. The first is as described in the record, but instead of finding evidence of left-axis deviation and T wave changes, such as one would expect with a large hypertensive heart and cardiac failure, no axis deviation is recorded and the T waves are low, with only a little elevation of the ST intervals in the precordial leads. There was a subsequent electrocardiogram, which is not mentioned in the abstract. It was taken on the next day and is essentially the same as the previous one, with possibly a little tendency to right-axis deviation, which is even more bothersome.

May we see the x-ray films? Dr. Lingley, did this patient have an obviously enlarged heart, as is stated in the record?

DR. JAMES R. LINGLEY. I have nothing to add to the x-ray report in the record. The heart shadow is greatly increased in size, but there is characteristic configuration. There is marked enlargement of all the pulmonary vessels on both sides, as well as hazy density in the medial portion of the lung fields, which is consistent with pulmonary edema. There is also fluid at both bases, more marked on the left than on the right.

DR. BLAND. You do not see any notching of the ribs?

DR. LINGLEY. No.

DR. BLAND. No evidence of pulmonary infarction?

DR. LINGLEY. No.

DR. BLAND. These films support the physical findings of heart failure of both the right and left sides. Does this suggest to you a rheumatic heart?

DR. LINGLEY. No, the shape of the heart does not suggest rheumatic heart disease.

DR. BLAND. The appearance of the electrocardiograms is disturbing and makes one wonder if rheumatic heart disease complicated the hypertension. If so, the heart should have been fibrillating, but it was not. I believe that we can discard that possibility. Do you see any calcification in the valves?

DR. LINGLEY. No.

DR. BLAND. So far as the remaining laboratory findings are concerned, the patient had a mild leukocytosis and a slight fever, but both might have been due to heart failure. Of the renal studies, the specific gravity should be noted. The specific gravity is sometimes helpful when one is considering the possibility of significant renal impairment in the presence of heart failure. The urine is usually concentrated in cases of heart failure and congested kidneys. If it is low, one is suspicious of considerable renal disease. In this case, the specific gravity is not suggestive of significant renal impairment. The cholesterol was normal. I suppose that it was determined in an attempt to appraise the renal function. There is one interesting laboratory finding, namely, the slightly elevated van den Bergh reaction. Whenever we see a patient with the

signs of heart failure who later develops jaundice, we begin to think about pulmonary infarction. On the other hand it occurs occasionally after a large myocardial infarct.

The subsequent course was unsatisfactory, in that the patient did not respond to the measures that usually relieve congestive failure unless some very serious underlying process is present. Such must have existed here, since he went progressively downhill, with a coincident sharp drop in blood pressure.

Was myocardial infarction responsible for his progressive unfavorable course? The electrocardiogram is not helpful and actually a little disappointing. On the other hand, when we add up the whole course of events, including the drop in blood pressure, the failure to respond to treatment and the seriousness of the underlying heart disease, I favor as a first choice a myocardial infarct, in spite of the absence of much pain. The second choice, which seems to me a little less likely, is that he had pulmonary infarcts. If present, I think that they were not primarily the cause of his fatal disease.

On the other hand, was this simply acute dilatation of a seriously weakened heart? The heart may dilate because of acute myocarditis from a variety of causes, — notably, rheumatic fever, diphtheria and acute nephritis, — but we have no reason to suspect such in this patient.

Did he have chronic vascular nephritis? The evidence pointing to the kidneys is not particularly convincing one way or the other. Certainly the patient had long-standing hypertensive vascular disease and, hence, probably an element of vascular nephritis. Whether the latter was sufficient to prevent his response to the measures that are usually satisfactory is difficult to say.

In conclusion, as a first choice I prefer myocardial infarction as the precipitating cause of this patient's final illness.

May I ask Dr. Sprague his opinion of these two electrocardiograms, both of which are essentially the same? They are surprisingly negative for a man who had had hypertension for fifteen years and eventually died of heart failure.

DR. HOWARD B. SPRAGUE. There seems to be some inversion in the T wave, the second one. If you want anything more to help in the diagnosis of myocardial infarction, I do not see it.

DR. BLAND. Would you object seriously to that diagnosis?

DR. SPRAGUE. I do not see how one can object. The statement that the pulse pressure did not vary with respiration makes one wonder if they were thinking about pericardial involvement. There was no friction rub. It might have been some unusual thing such as a ruptured coronary artery with hemopericardium.

DR. BLAND. It seems to me that one bit of evidence against a significant amount of cardiac tamponade,

if you want to go that far, is that there was a lot of blood in the pulmonary circuit according to the x-ray films. Therefore it would not appear that there was a process sufficiently constricting to have prevented the flow of blood into the heart.

DR SPRAGUE: There is nothing in the electrocardiogram to support a diagnosis of pericardial irritation.

DR TRACY B MALLORY: Dr Lerman, will you tell us the impression on the wards?

DR JACOB LERMAN: From the story we thought that this patient had had an acute coronary occlusion, which precipitated congestive failure. The thing that bothered us was his failure to respond to what we thought was adequate therapy. He continued to go downhill, coughing considerably, and developed marked Cheyne-Stokes respiration. There was no explanation for it except to assume that he had had a large coronary occlusion with cardiac damage.

CLINICAL DIAGNOSES

Hypertensive heart disease
Myocardial infarction

DR BLAND'S DIAGNOSES

Cardiac infarction
Hypertensive heart disease
Cardiac failure

ANATOMICAL DIAGNOSES

Pericarditis, acute, fibrinous
Cardiac hypertrophy, hypertensive type
Nephrosclerosis, moderate
Peptic ulceration of stomach and duodenum, acute
Hydrothorax, bilateral
Arteriosclerosis, aortic and coronary, slight
Chronic passive congestion
Hypertrophic arthritis of spine

PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy showed several things, and I do not know how to put them together. The unexpected finding was an acute pericarditis. There was also considerable hypertrophy of the heart, the weight being 600 gm, but the heart was not particularly dilated. There was diffuse congestion of the lungs, and in places some evidence of old organizing bronchopneumonia. There was quite severe arteriolar sclerosis in the kidneys, such as one would expect with long-standing hypertension. The questions are: Why did he have pericarditis? What did the pericarditis have to do with the symptoms?

It was a fibrinous pericarditis, rather than the purulent one that accompanies bacterial infection. There are several types of nonbacterial pericarditis. It is a frequent finding with an infarct of the heart, but there was no infarct of the heart here. Fibrinous pericarditis is also quite frequent in patients dying

in uremia, but we have little evidence that this patient died with uremia, since the highest non-protein nitrogen was only 52 mg per 100 cc. The kidneys showed vascular involvement but not the extensive atrophy of the parenchyma that one would expect in a patient who had died of renal insufficiency.

There were some other incidental findings that are peculiar, and again I cannot explain them. There were multiple acute ulcers in the stomach and duodenum. Acute gastroenteritis is often observed in the uremic state, and it can also occur in cases of simple cardiac failure. This, however, looked more like peptic ulceration than the usual superficial changes that one sees in either uremia or cardiac failure. I cannot tie the ulcers into the picture. We recorded the primary cause of death as acute pericarditis, but I have no idea of its origin or etiology.

DR BLAND: What about the myocardium? Was there any evidence of myocarditis?

DR MALLORY: We could not find a thing wrong with it, except hypertrophy.

DR ALLEN G BRAILEY: Would tuberculous pericarditis do it?

DR MALLORY: There was no evidence of tuberculosis.

DR JAMES B TOWNSEND: Was there any fluid in the pericardium?

DR MALLORY: Only a moderate amount, but quite a lot of fibrin. It looked at autopsy like the pericarditis that one sees with uremia.

DR BLAND: Was there cardiac tamponade?

DR MALLORY: I do not believe that there could have been.

CASE 32182

PRESENTATION OF CASE

First admission. A sixty-three-year-old Italian woman entered the hospital complaining of dyspnea, nausea and vomiting.

The patient had been well until four months before admission, when she had a sudden attack of dyspnea, chills, a fever of 103°F and pain in the right posterior chest. The pain was constant, not related to breathing and lasted one week. After two more weeks she felt well enough to resume her work as a chocolate dipper but she still complained of some weakness and exertional dyspnea. One week before admission, while stooping over a kettle of chocolate, she suddenly felt weak and dizzy, as if she were going to faint. She sat down in a chair and felt better, but fifteen minutes later she became nauseated and vomited her breakfast. She was then brought to the Emergency Ward, where she appeared to be in no acute distress but did complain of a vague feeling of fullness and burning in the epigastrium, with radiation to the right chest and "up into the head."

In the past her health had always been good except for occasional bouts of acid eructations

Physical examination revealed an elderly woman in no acute distress. The lungs were clear, and the heart was not enlarged. The pulmonic second sound was slightly greater than the aortic. There was slight tenderness to deep palpation in the epigastrium.

The temperature was 99°F, the pulse 124, and the respirations 26. The blood pressure was 170 systolic, 92 diastolic.

Examination of the urine showed a +++ test for albumin. The blood showed a hemoglobin of 90 per cent and a white-cell count of 13,500. The non-protein nitrogen was 23 mg per 100 cc. An electrocardiogram was read as normal except for sinus tachycardia. An x-ray film of the chest revealed linear areas of increased density in the posterior portion of the right lower lobe and general enlargement of the heart. A gastrointestinal series was negative.

On the following morning the patient felt entirely well and was discharged.

Final admission (five days later). At home she continued to vomit almost everything consumed. She felt constantly nauseated and had frequent acid eructations, with the same type of epigastric burning radiating to the right chest and neck. She had also experienced some dyspnea even at rest, but had no orthopnea, ankle swelling, cough, fever or leg pain.

On physical examination the patient appeared acutely ill. She was breathing rapidly but was not orthopneic. The skin was warm and moist, and the lips were slightly cyanotic. The neck veins were distended and pulsating. The heart, lungs and abdomen were the same as on the previous examination. There was questionable bilateral calf tenderness, but Homans's sign was negative.

The temperature was 98°F, the pulse 85, and the respirations 40. The blood pressure was 100 systolic, 70 diastolic.

The blood and urinary findings were essentially similar to the previous results. A repeat electrocardiogram showed normal rhythm, at a rate of 105, with a tendency to right-axis deviation. The PR interval was 0.14 second. T_1 was upright, T_2 and T_3 inverted, Q_1 prominent, TCF_1 and TCF_2 inverted except for a few upright TCF_4 complexes, and TCF_3 upright.

The patient's condition grew steadily worse. On the second hospital day the temperature spiked to 103°F and remained elevated. On the third day a definite gallop rhythm was heard at the base of the heart. On the fourth hospital day a definite swelling of the right calf was found. She became more cyanotic, dyspneic and apprehensive. Femoral-vein ligation was considered, but the patient expired before preparations could be completed.

DIFFERENTIAL DIAGNOSIS

DR SYLVESTER MCGINN. Perhaps we should start by seeing the x-ray films.

DR JAMES R. LINGLEY. There are two sets of films, taken nine days apart. At the first examination the heart shadow is slightly enlarged. There are some bands of density in the right midlung field that have the appearance of old scars, which could have been due to infarcts in the past or to a scarring process of any nature. The second set shows an increase of 1 cm. in the transverse diameter of the heart. The diaphragm is higher in position, however, and this can explain the slight increase in the transverse diameter of the heart. The left lung field is clear. The right shows an area of increased density in the region of the base of the upper lobe. This shadow is rather indefinite, but I think that whatever caused it appeared between the two examinations.

DR MCGINN. I have just been handed the electrocardiograms. The first one was described in the abstract as normal, but on looking at the tracing it is quite abnormal in that it has deeply inverted T waves in Leads 2 and 3, which makes quite a bit of difference in the summary of the case. It might have made a difference in its handling.

There are three types of presenting symptoms — shortness of breath, epigastric discomfort associated with nausea and vomiting and pain in the right chest radiating to the neck, which I interpret as having been due to diaphragmatic irritation with distribution of the pain through the phrenic nerve. The major findings in the case, however, are those of acute right ventricular strain. One week prior to the final admission, we know that she had severe shortness of breath, a feeling of fullness in the mid-epigastrium and tenderness on palpation over the liver area. I believe that that was due to acute hepatic congestion. Sometimes acute congestion of the liver can be extremely painful and simulate an acute abdomen. There is also a note that the pulmonic second sound was louder than the aortic, the reverse of what one would expect, particularly with a blood systolic pressure of 170. Then there was radiation of pain to the neck, which I referred to previously as probably having been due to diaphragmatic pleurisy.

On the final admission the patient had cyanosis, rapid breathing, distended neck veins and a fall of blood pressure. These findings are consistent with strain on the right ventricle. A gallop rhythm was heard at the base of the heart. If gallop rhythm is due to left ventricular dilatation it is usually heard at the apex. When heard at the base of the heart, it is likelier to be due to right ventricular dilatation, particularly if it is in the region of the pulmonary conus. That is not an unusual finding in cases of pulmonary embolism. Then there was a change in the electrocardiogram, in that some ex-

dence of right-axis deviation appeared, which is further evidence of right ventricular strain. Later on, she had some calf tenderness and preparations were made for ligation.

Diaphragmatic hernia may cause undue strain on the chambers of the right heart. It is unusual. If she had had a small diaphragmatic hernia it is possible that suddenly a large part of the stomach went through the diaphragm into the chest and caused an acute compression of the lung. In this case a negative gastrointestinal series was reported, and I think that this diagnosis can be ruled out on that basis, as well as the facts that she had had no previous history of diaphragmatic hernia and that it is an extremely rare condition. I* reported one, and one other case has been reported in the literature. The symptoms in both cases were identical with those of massive pulmonary embolism.

That leaves us with acute cor pulmonale, the sudden distention and dilatation of the chambers of the right heart secondary to obstruction in the pulmonary circulation. The most frequent cause is acute pulmonary embolism. I believe that this patient did have a pulmonary embolus. I have confidence in the electrocardiogram and will have to make a diagnosis of coronary thrombosis on this tracing, even though the history is far from typical. There is nothing in the type of pain to make one think of coronary thrombosis, but we cannot get away from the first electrocardiogram, which shows no evidence of pulmonary embolism, but rather a coronary type of electrocardiogram consistent with posterior myocardial infarction due to occlusion of the right coronary artery. If that assumption is correct, she did have a previous coronary thrombosis. The incidence of pulmonary embolism and infarction in cardiac patients is so high that I believe they were also present in this case, coincident with coronary thrombosis.

DR DONALD KING: Do the x-ray films show evidence of old pulmonary infarction?

DR LINGLEY: There are scars in the right lung that are consistent with old infarcts. The shadow that appeared between the two examinations is consistent with a fresh infarct.

DR KING: You would expect to find evidence of old infarction?

DR LINGLEY: The x-ray findings are consistent with it.

*McGinn, S., and Spear, L. M. Diaphragmatic hernia presenting clinical picture of acute cor pulmonale. *New Eng J Med* 224:1014-1018, 1941.

DR. FRED ALEXANDER: Does Dr. Sprague think that the inverted T waves in Leads 2 and 3 can be interpreted as evidence of cardiac disease of long standing?

DR SPRAGUE: I think that they could, but this does not look like a case of that type. The patient had a systolic pressure of 170, with a low diastolic pressure.

CLINICAL DIAGNOSES

Pulmonary infarction
Thrombophlebitis, right leg
Myocardial infarction

DR MCGINN'S DIAGNOSES

Acute cor pulmonale
Pulmonary emboli and infarcts
Coronary occlusion (old)
Thrombophlebitis, right leg

ANATOMICAL DIAGNOSES

Pulmonary embolism, massive, bilateral
Pulmonary infarcts, multiple, healed
Focal infarction of left auricle
Mural thrombus, left auricle
Thrombophlebitis, superficial femoral and popliteal veins of left leg

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: The autopsy showed as the immediate cause of death a massive pulmonary embolus that filled the major branches of both the right and the left pulmonary arteries. We also found in the lungs a number of old scars, which were quite characteristic of healed infarcts. There was not, however, any marked degree of cor pulmonale, and no gross evidence of myocardial infarction was noted at autopsy. A small partially adherent thrombus was present in the left auricle. Sections were made through that auricle, and there were several microscopic areas of infarction in the auricular muscle. I am throwing Dr. McGinn a lifeline, but I am not sure that that explains the electrocardiogram. The major coronary arteries were in fairly good shape, with just a few widely scattered patches of atheroma. Ante-mortem thrombi were found in the superficial femoral and popliteal veins of the left leg. There can be little doubt that these represented the source of the pulmonary emboli, since the veins of the right leg were normal and the auricular thrombus was on the left side of the heart.

THE INADEQUACIES OF MEDICAL CARE

IV THOSE CONCERNING ITS ADJUNCTS

GIVEN proper distribution and cost of high-grade medical care, little can be accomplished if the necessary adjuncts are lacking, such as well equipped hospitals, adequate nursing personnel and continued progressive research concerning disease.

As stated in one of the previous editorials, lack of hospitals and poorly equipped hospitals are two of the chief reasons why recently graduated physicians refuse to settle in rural districts and certain small cities. Such a situation usually exists because these communities cannot afford to create or maintain such facilities. No doubt this inadequacy would be lessened by proposed national

legislation to build hospitals in areas of demonstrated need (Hill-Burton Bill), but to ensure a high quality of medical care, it may be necessary to employ full-time or to subsidize chiefs-of-service who have been properly trained.

Even in the large cities in which, ten years ago, there was considered to be a superabundance of hospital beds, it is now almost impossible to obtain space even for the patient who becomes seriously ill. This condition has chiefly resulted from two causes. In the first place, physicians and laymen have become aware of the fact that a moderately or critically ill patient can be cared for far better in a modern hospital than in the home, secondly, the widespread and enthusiastic support of Blue Cross plans has greatly increased the number of persons who, when ill, seek hospitalization. Obviously, to meet this demand present hospitals must be enlarged and new hospitals must be built, but some relief would result if better use were made of existing facilities—for example, hospitals could be placed on a seven-day week and rules limiting the period of convalescence could be enforced. The latter might be assisted by the creation of affiliated convalescent departments or homes.

For many years standards for the approval of hospitals, both regarding equipment and personnel, have been set by the Council on Medical Education and Hospitals of the American Medical Association and by the American College of Surgeons. More recently, certain states, including Massachusetts, have designated minimum requirements for approval by the appropriate state department. All this has resulted in a tremendous improvement in hospitals, but a great number are still substandard because they are either poorly equipped or inadequately staffed, or both. Further improvement seems to rest solely in state regulation, but the administrative boards and officers of nonprofit institutions could do a great deal to correct existing faults.

For hospitals in rural districts and small cities, the adoption of a plan similar to that sponsored by Bingham Associates Fund seems distinctly worth while. Under this scheme, consultative clinical and laboratory services, as well as opportunities for continued professional and technical training, are

available to numerous community hospitals in Maine through their affiliation with hospitals in two relatively large cities, Lewiston and Bangor, the latter, in turn, being affiliated with a large teaching unit, the New England Medical Center, in Boston

Lack of nursing personnel is another contributing factor to inadequacy of medical care. During the war, this scarcity was to be expected, although there seems to be no doubt that the armed forces demanded and obtained more nurses than they knew how to utilize. There appears, however, to be reason for believing that the shortage will continue, inasmuch as many of these nurses, having realized the advantages of relatively well paid and secure jobs, are loath to request discharge. Whether a sufficient number of young women can be induced to enter the nursing profession is doubtful, but an increase in facilities for the training of attendant or practical nurses would do much to relieve the present shortage. For this type of training the preliminary requirements are less demanding and the training period is of shorter duration than is the case with regular training schools, on the other hand, the young women who graduate are usually qualified to give routine care in hospitals, convalescent homes and private homes. Massachusetts and seventeen other states have already established schools for the training of attendant nurses, and have created boards for their licensing, and a nation-wide adoption of such a program would be advantageous.

Medical care cannot improve, all other things being equal, unless it receives the continued benefit of research in the cause and treatment of disease. Although a great deal was accomplished by relatively inco-ordinated research prior to the war, the advances made under the supervision of the Committee on Medical Research of the Office of Scientific Research and Development leave no doubt concerning the advantages of integrated investigation. Furthermore, efforts should be directed toward the diseases that are chiefly responsible for crippling and death, such as arthritis, cardiovascular diseases and cancer. As an example of the inconsistencies in the latter regard, it should be noted that the National Foundation

for Infantile Paralysis was able to raise over \$16,000,000 in 1945, whereas the American Cancer Society could only obtain about \$4,000,000. Finally, it should be borne in mind that, with taxation as high as it is at the moment and little probability that it will be appreciably reduced in the near future, contributions from individuals and groups for the furtherance of medical research will necessarily grow smaller and smaller. For these reasons proposed national legislation for the promotion and support of scientific research (Kilgore and Magnusen bills) seems not only proper but indispensable.

The practicing physician has little or no control over most of the above adjuncts of medical care but all of them have a lot to do with the health of the people and all schemes aimed at improvement should receive the enthusiastic and energetic support of the medical profession.

H R 5296

MRS CLARE BOOTHE LUCE, Representative of the 4th Connecticut District, has introduced in the House of Representatives a bill notable in two respects: it recognizes an extra burden that is almost implicit in the practice of the healing arts, and it is, pleasantly, one of the shortest documents of its nature that we have yet had the privilege of reading.

The full text of H R 5296 is as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled That section 23-g of the Internal Revenue Code is amended by adding the following new paragraph, to read as follows:

"(4) That commencing with the taxable year 1944 physicians, surgeons and dentists shall be allowed an additional credit as a deduction on their income tax equivalent in terms of percentages to that portion of their time each year which is devoted to charity, free clinic work, and/or public research work,

"(5) The Commissioner of Internal Revenue shall prescribe by regulation the method of computing such time and the proof which shall be required in substantiation thereof."

This bill of the Connecticut congresswoman is obviously, a mere outline, an earnest of a good intention of which the practical details, if it should receive favorable consideration, would require amplification and interpretation. We have no idea of the reception that the bill will receive at the hands of the Committee on Ways and Means.

which it has been referred, but it is heartening to have a lawmaker take sympathetic recognition of the fact that medical practice is one of the most generous and unselfish branches of public service. In strict interpretation, we imagine, of that which the doctor's daily life suffereth long and is kind, which envieth not, vaunteth not itself and is not tied up, may prove to be a problem for the Commissioner of Internal Revenue. May he have faith and may we have hope if such an opportunity presents his way! In the meantime, those who approve of this measure should communicate their interest to some member of the Committee on Ways and Means.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

LIMITED SUPPLY OF IMMUNE SERUM GLOBULIN

The current measles epidemic has created an unprecedented demand for immune serum globulin, which threatens to exhaust the available supply. Physicians are therefore urged to limit their use of this product to cases in which the need is clearly indicated, and to select modification rather than temporary protection, unless protection is definitely required. Temporary protection against measles can usually be obtained in exposed susceptible persons by administering 0.1 cc. globulin per pound of body weight (but not over 10 cc.) within the first six days after exposure. It is recommended for infants from six months to two years old and for older children who are debilitated, ill or faced with an emergency, such as travel or surgery. The protection so obtained does not last more than about three weeks.

Modification is desirable in other exposed susceptible persons, and may be obtained by giving 0.025 cc. per pound of body weight (equivalent to 1 cc. for a 40-lb child) within six or seven days after the date of exposure. Modified measles usually results in permanent immunity.

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	CLINIC CONSULTANT
Flaverhill	May 1	William T. Green
Lowell	May 3	Albert H. Brewster
Walem	May 6	Paul W. Hugenberger
Brockton	May 9	George W. Van Gorder

Springfield	May 21	Garry deN. Hough, Jr.
Fall River	May 27	David S. Grice
Hyannis	May 28	Paul L. Norton

Physicians referring new patients to clinics should get in touch with the District Health Officer to make appointments.

CORRESPONDENCE

A MISSTATEMENT

To the Editor: There recently appeared in the newspapers of Boston a statement, made by ex-representative Niland, of East Boston, before a legislative hearing at the State House, that the Health Commissioner of Boston was a graduate of the College of Physicians and Surgeons, of Shawmut Avenue, Boston.

This is absolutely untrue, since I graduated from Harvard Medical School in 1903, with postgraduate work at the Rotunda Hospital, Dublin, Ireland, in 1903-1904.

Except for several years during World War I and World War II during which time I served with the United States Navy, I have been associated with the Boston Health Department since September, 1904, in various positions.

I have also attended the public-health schools of both Harvard and Johns Hopkins.

FREDERICK J. BAILEY, M.D.
Health Commissioner

BOOK REVIEWS

Endocrinology of Woman. By E. C. Hamblen, M.D. 4°, cloth, 571 pp., with 157 illustrations. Springfield, Illinois: Charles C. Thomas, 1945. \$8.00.

This book is divided into five parts.

Part one deals with the endocrine glands—their history, embryology, anomalies, anatomy, histology, secretory control, chemistry, physiology and interrelations. Following the introductory chapter, separate chapters are devoted to the thyroid gland, the adrenal glands, the pancreas, the parathyroid glands, the ovaries, the testes, the pituitary gland, the pineal gland and the thymus. The author justifies the inclusion of the testes in this presentation on the basis "that detailed knowledge of this gland is necessary for any real orientation of the problems of intersexuality, androgen therapy of woman, virilizational syndromes and sterility."

Part two is concerned with applied endocrine physiology and discusses in detail antenatal growth and sexual differentiation, childhood development, sexual maturation, sexual maturity (menstruation, conception and gestation) and sexual regression.

Fifty-seven pages, comprising the third part, are devoted to endocrine diagnostic methods. This portion of the book is well illustrated and covers all the known clinical methods of endocrine diagnosis. The laboratory procedures useful in the diagnosis of normal and abnormal levels of endocrine function are alluded to, the normal values are emphasized throughout, so that abnormal values may be more easily recognized.

In part four the various functional disorders of the endocrine glands are discussed, and the effect of these glandular diseases on the sexual and reproductive functions of woman is stressed.

Part five contains eighteen chapters on endocrinology applied to gynecologic disease, and deals with such subjects as abnormal skeletal growth, abnormal sexual differentiation, obesity and leanness, abnormal uterine bleeding, functional uterine bleeding during adolescence, functional uterine bleeding during the childbearing age, dysmenorrhea, dermatologic abnormalities, cyclomastopathy, menstrual headaches and other cyclic syndromes, complications of pregnancy, complications of the puerperium, the incidence and causes of sterility, diagnostic methods in cases of sterility, the treatment of sterility, tumorigenesis, complications of the climacteric and commercial endocrine preparations. Only those commercial endocrine preparations with which the author is familiar are listed, but it is stated that omission of preparations from this list does not imply their inferiority.

The complex material of endocrinology of woman, well presented in this book, makes interesting reading. The illustrations are original, numerous, well chosen and clearly executed. Considerable material is condensed in tables throughout the text and the extensive bibliography at the conclusion of each chapter represents a compendium of the literature on the subject.

The 1944 Year Book of Industrial and Orthopedic Surgery. Edited by Charles F. Painter, M.D. 12°, cloth, 452 pp., with 282 illustrations. Chicago: The Year Book Publishers, 1945. \$3.00.

The editor has again compiled a most readable year book. He summarizes in a sufficiently descriptive but yet concise

manner the pertinent, reported happenings in the field of orthopedic surgery and industrial medicine. He has skillfully avoided the Scylla and Charybdis of most year books—a book that reads like a catalog or a volume that is so prolix that the reader yawns before the paragraph is completed. There is a definite place for a skillfully written synopsis and logically arranged index of the year's significant contributions in this field. Every reader will doubtless be disappointed at the absence of certain current papers that he, the reader, considered of value. The author's selection of papers, however, has been good. This volume should be of great aid to the busy surgeon in keeping abreast of current happenings in orthopedic surgery.

Shoulder Lesions. By H. F. Moseley, M.A., D.M., M.Ch. (Oxon.), F.R.C.S. (Eng. and Can.) 4th, cloth, 181 pp., with 70 illustrations. Springfield, Illinois: Charles C. Thomas, 1945. \$4.50.

The author has summarized in a concise and attractive manner present-day knowledge of disabilities of the shoulder. In doing this he has drawn on his wide experience in treating these lesions both in London and in Montreal. He shows how pitifully inadequate is modern knowledge of shoulder function and its disturbances. There are numerous well chosen illustrations. Chapters on x-ray interpretation and x-ray treatment and on operative procedures are included. Treatment is discussed in sufficient detail. A useful chapter giving thirty-one illustrative case histories completes the book.

Although no orthopedic surgeon will agree in toto with the author's conclusions, the sensible approach and the careful analysis of these lesions will meet with general approval. It can be recommended heartily as a readable and helpful book for all those interested in such disabilities.

NOTICES

ANNOUNCEMENTS

Dr. Edward A. Edwards announces his return to Boston at 374 Marlboro Street, his practice being limited to surgery, with special interest in peripheral vascular disease.

Dr. L. Robert Weiss, having returned from active service with the United States Army, has resumed the practice of allergy at 483 Beacon Street, Boston.

Dr. Ralph H. Wells announces his return from military service and the reopening of his office for the general practice of medicine at 1430 Massachusetts Avenue, Lexington.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston

Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCE PROGRAM

Friday, May 3 — Clinical Diagnosis of Patent Ductus Arteriosus. Dr. Samuel A. Levine.

Wednesday, May 8 — Fluorine and Dental Caries. Dr. Basil G. Bibby.

Friday, May 10 — Psychotherapeutic Opportunities for the General Practitioner. Dr. Erich Lindemann.

Wednesday, May 15 — Silent Chest Lesions. Dr. Richard H. Overholt.

Friday, May 17 — Clinicopathological Conference. Drs. Stanley Bradley and H. E. MacMahon.

Wednesday, May 22 — Hyperadrenocorticism. Dr. Robert H. Williams.

Friday, May 24 — Application of Radioactive Iodine in the Treatment of Graves Disease. Dr. Saul Hertz.

Wednesday, May 29 — War Experiences in Abdominal Surgery. Dr. Charles S. Welch.

Friday, May 31 — The Role of Infection in Shock. Dr. Joseph C. Aub.

On Tuesday and Thursday mornings, Dr. S. J. Thannhauser will give medical clinics on hospital cases. On Saturday mornings, clinics will be given by Dr. William Dameshek. Medical rounds are conducted by some of the staff members from 12:00 to 1:00 in the Lecture Hall.

All exercises are open to the medical profession.

BOSTON UNIVERSITY SCHOOL OF MEDICINE ALUMNI ASSOCIATION

The annual alumni reunion and continuation course Boston University School of Medicine will be held on and Saturday, May 10 and 11.

The continuation course will be held in the auditorium of the medical school this year, because its popularity has made more spacious accommodations necessary. There will be a nominal registration fee of \$1.00 for each of the three days.

On Saturday, May 11, at 6:00 p.m., in the Georgian Room and Parlor A, Hotel Statler, there will be a reception for the faculty members. At 7:00 p.m. there will be the annual dinner and banquet. The speakers will include President L. Marsh, Dean Donald G. Anderson, Dr. Reginald H. Wick and the speaker of the evening, Dr. James R. M. Hartford, Connecticut. Dr. Miller is going to speak on the topic "The National Health Program of the American Medical Association." Dr. Miller is a member of the Board of Trustees of the American Medical Association, and president of the New England Surgical Society. The tickets will be \$7.00 each. Dress is optional.

NEW ENGLAND PEDIATRIC SOCIETY

The Spring meeting of the New England Pediatric Society will be held on Wednesday, May 15.

A day of clinical activities will be presented by Dr. M. Butler and members of his staff at the Massachusetts General Hospital. Dr. Edwards A. Park, professor of pediatrics, Johns Hopkins Hospital, Baltimore, Maryland, will be the speaker following the dinner.

NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The spring meeting of the New England Obstetrical and Gynecological Society will be held in Worcester on Friday, May 29, with headquarters at the Wachusett Club.

AMERICAN CONGRESS OF PHYSICAL MEDICINE

The twenty-fourth annual scientific and clinical sessions of the American Congress of Physical Medicine will be held September 4 to 7, inclusive, at the Hotel Pennsylvania, New York. Scientific and clinical sessions will be given each day. All sessions will be open to members of the American Medical Association in good standing with the American Medical Association. In addition to the scientific sessions, the annual institute courses will be held September 4, 5 and 6. These courses will be open to physicians and to therapists registered with the American Registry of Physical Therapy Technicians.

For information concerning the convention and the instruction course, address the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, MAY 9

FRIDAY, MAY 10
*10:00 a.m. - 12:00 p.m. Medical Staff Rounds. Peter Best 1 Hospital.

12:00 p.m. - 1:00 p.m. Clinicopathological Conference (Boston City Hospital). Joseph H. Pratt Diagnostic Hospital.

MONDAY, MAY 13
*12:00 p.m. - 1:00 p.m. Clinicopathological Conference. Peter Brigham Hospital.

TUESDAY, MAY 14
12:00 p.m. - 1:00 p.m. Dermatological Service. Grand Rounds. Theater. Dowling Building. Boston City Hospital.

*12:15 - 1:15 p.m. Clinicoroentgenological Conference. Peter Brigham Hospital.

WEDNESDAY, MAY 15
*10:30 - 11:30 a.m. Medical Clinic. Isolation Building. Amphlett Children's Hospital.

A VISIT WITH OSLER*

REGINALD FITZ, M D †

BOSTON

THOSE of us who were house officers at the Massachusetts General Hospital during the summer of 1910 will remember that the weather seemed continuously hot and that a great many citizens appeared to have typhoid fever. The medical wards were filled with the disease, during June, July and August we grew almost too familiar with its looks and with the dire manifestations of hemorrhage or perforation. But there were compensations: our sickest patients somehow often managed to grow well, not all hemorrhages were fatal, occasionally our surgical colleagues would sew up a perforated intestine and make us realize the miracle of modern surgical skill, and certainly we learned a great deal about an important infection.

August 25 was a particularly hot day. Even the newspapers commented on the high humidity, and we who were due to work in town over the week end read a little enviously about some of our more fortunate friends who were in the country indulging in the frivolities of tennis or golf. But on that day we had one reward that more than made up for the heat and our worries. Dr Osler accompanied the visit.

The East Medical Service by tradition is always justifiably proud — proud of its history, of the names on its roster, of the manner in which it does things. At that particular time Dr F Gorham Brigham was senior, Dr William S Parker was "pup," and I was junior. During the previous four weeks we had been exposed to a new experience. Our regular visiting man, Dr James J Minot, had turned over the service to Dr Joseph H Pratt. He was then a relatively new importation from Johns Hopkins and seemed fairly to bristle with ideas and energy, among other accomplishments he had gone so far as to introduce the interesting novelty of dictating notes on some of the cases so that our records had in his own words exactly what he thought of them. By and large, to make rounds with him proved an exciting adventure.

On that morning the visit started as usual. We were upstairs in Ward 30 and according to custom

had started to move around in clockwise manner when in blew Osler †. He came unannounced and unexpectedly. There was no need for any introductions, since Dr Pratt knew him well and we house officers had heard him speak at the Harvard Medical School on a memorable occasion during the preceding year, so that we were familiar with his appearance — his short figure, his mustache, his keen eyes. Now we were at once delighted by him — in part, perhaps, because to have a distinguished visiting professor from England was by no means a usual happening, even for the East Medical Service, chiefly, because instead of observing the amenities by commenting on the weather or the state of our health, he immediately became part of us by asking, "What have you got here?"

Here was a young woman who had just been transferred from the surgical ward. She had entered the hospital for the removal of a fibroid; everything had gone smoothly for fifteen days, when she was suddenly seized with pain over the right lower chest and with dyspnea and fever. On physical examination, when we first saw her, her heart seemed a little displaced outward, and at the right base below the angle of the scapula was an area of dullness, with distant bronchial breathing and voice transmission that sounded unusually close to the ear. We believed that she had a pulmonary infarct. Dr Brigham, whose privilege it was to present to the visit each morning the patients with their histories and physical findings, asked Dr Osler what he thought of the situation. Osler did no more than demonstrate the technic of palpatory percussion by tapping the young woman's back with all the fingers of one hand, and having done so said, "The resistance is quite marked, isn't it?" Dr Pratt, recalling Oslerian teaching of the importance of increased tactile resistance in the recognition of hydrothorax, asked if he thought the patient had a collection of fluid in her chest. Dr Osler was noncommittal, all he would say was that the resistance was striking, and finally that it might be well to insert a needle.

*From the East Medical Service of the Massachusetts General Hospital.
†Lecturer on the history of medicine, Harvard Medical School.

†Dr Pratt gives a somewhat different account of Dr Osler's visit.
Boston M & S J 196 83 89, 1927.

Dr Brigham performed this operation on the following day and removed 400 cc of fluid. The patient subsequently developed a recognizable phlebitis in the left leg and later in the right leg, and in the course of time made an uneventful recovery. None of us have forgotten the skill with which Dr Osler demonstrated so nicely one of the essential signs of fluid, nor the tactful manner in which he suggested its removal.

The next patient had come to the hospital a week before because following a curettage she had begun to lose weight and strength, had become increasingly pale and had finally developed purpuric spots over both lower legs. On physical examination she proved to be feverish and to have a loud murmur at the precordium and a palpable spleen. She was markedly anemic and her blood culture was positive for what the bacteriologists regarded as an atypical pneumococcus. For want of any better treatment she had been given 5 gr of potassium iodide three times a day, and forty-eight hours later we observed that a painful, peculiar-looking bullous eruption had developed on her face and arms.

When Dr Osler noticed the rash, he sat down in a chair by the young woman's bedside and apparently paid no attention to her infectious endo-

medical literature as was he. And I suspect that he began by telling us that here was something curious in the medical line. He may have reminded us of that little known periodical *The New York Medical Gazette and Journal of Health* and of the paper in it by Dr John O'Reilly — almost invariably misspelt O'Reilly — entitled "On the Effects consequent on the Administration of Iodide of Potassium, illustrated by cases," which appeared in January, 1854. For this makes pleasant reading and tells almost the whole story.

When a patient has been taking Iodide of Potassium for some days — probably on account of some peculiarity in his constitution — he is suddenly attacked with symptoms of fever, and almost contemporaneously with this disturbance of his system, will be observed on his forehead and face spots, varying in size and irregular in form, of a dark red color. As the case goes on, the spots will be found on the chest and upper extremities, and ultimately will appear on the lower part of the trunk and lower extremities. The spots will gradually become darker, and eventually assume a purple color. After some time the cuticle will be seen elevated over an odd macula, or filled with a fluid of a purple color, in a short time the cuticle becomes detached, and the subjacent parts, including the true skin and cellular substance will be remarked to be sphaculated to a greater or less extent — as the case progresses, the dead part will be thrown off, leaving ulcers of a considerable depth, or rendering the patient miserable by the total annihilation of an important organ.

With respect to the diagnosis between purpura and the Iodine disease, it will be noted that in the former the maculae appear on the lower extremities first, and that the disease almost invariably occurs in those whose constitutions have been broken down by long sea voyages, or are suffering under some other disease — such as typhus fever, phthisis, anasarca, chlorosis, or some other debilitating malady. Again, there is no pyralism — no bullae — no disagreeable odor — no constitutional derangement — but the grand characteristic distinction consists in the eruption. In the Iodine diseases, like the exanthemata, it shows itself first on the face, while in purpura it appears on the legs.

Or he may have referred to the paper by Hyde that appeared in the *Archives of Dermatology* in October, 1879 and that described all the known cases of a bullous rash developing after the administration of iodides. Not many had been reported, but they all were much alike. This type of rash may develop even after very small doses of the drug have been taken. It usually appears on the face, neck and dorsal surface of the arms and hands, and as a vesicle that rapidly increases in size and may remain discrete or may coalesce with neighboring vesicles to form bullae. In two thirds of Hyde's cases there were cardiac or renal complications, so that he put the question that others have asked since and that has never been answered satisfactorily. Why should patients with heart or kidney disease be predisposed to develop such an unusual type of skin reaction to iodine?

As I remember the scene, Dr Osler gave the impression of recognizing at a glance an uncommon clinical picture and then went on to show how a good clinician under such circumstances at once begins searching for similar cases. He and Dr Pratt were soon interchanging a barrage of names and literary allusions that were far over the heads

FIGURE 1 Bullous Eruption after Iodide Administration
"Over the backs of the hands and forearms are curious semi-spherical nodules ranging from 3 to 17 mm in diameter. The average size is 7 mm. A few are situated in the upper half of the forearms and are symmetrical. Today most of them are infiltrated with blood, have a bright, shining appearance and in color are from light to dark purple. Some are still firm, the larger ones are soft and fluctuant. They were quite tender at the start." (East Medical Records note by Dr Joseph H Pratt)

carditis, in which I, at least, assumed he might be interested. Instead, he began to talk about the rarer skin lesions that may develop following the use of iodides.

I wish that I could remember exactly what he said and how he said it. I am sure that he paid us the compliment of pretending to assume — since we youngsters recently had been welcomed to the company of educated men at a Harvard Commencement — that we were as familiar with

of the rest of us. And the upshot was that we proceeded to the Treadwell Library to see what we could find. In those days the Treadwell Library was an ideal working library — a lovely room overlooking down from the walls benignantly at any readers, with a large central table at which one could spread out material to one's heart's content, and with shelves around the room containing enough books and periodicals so that surely one could find all

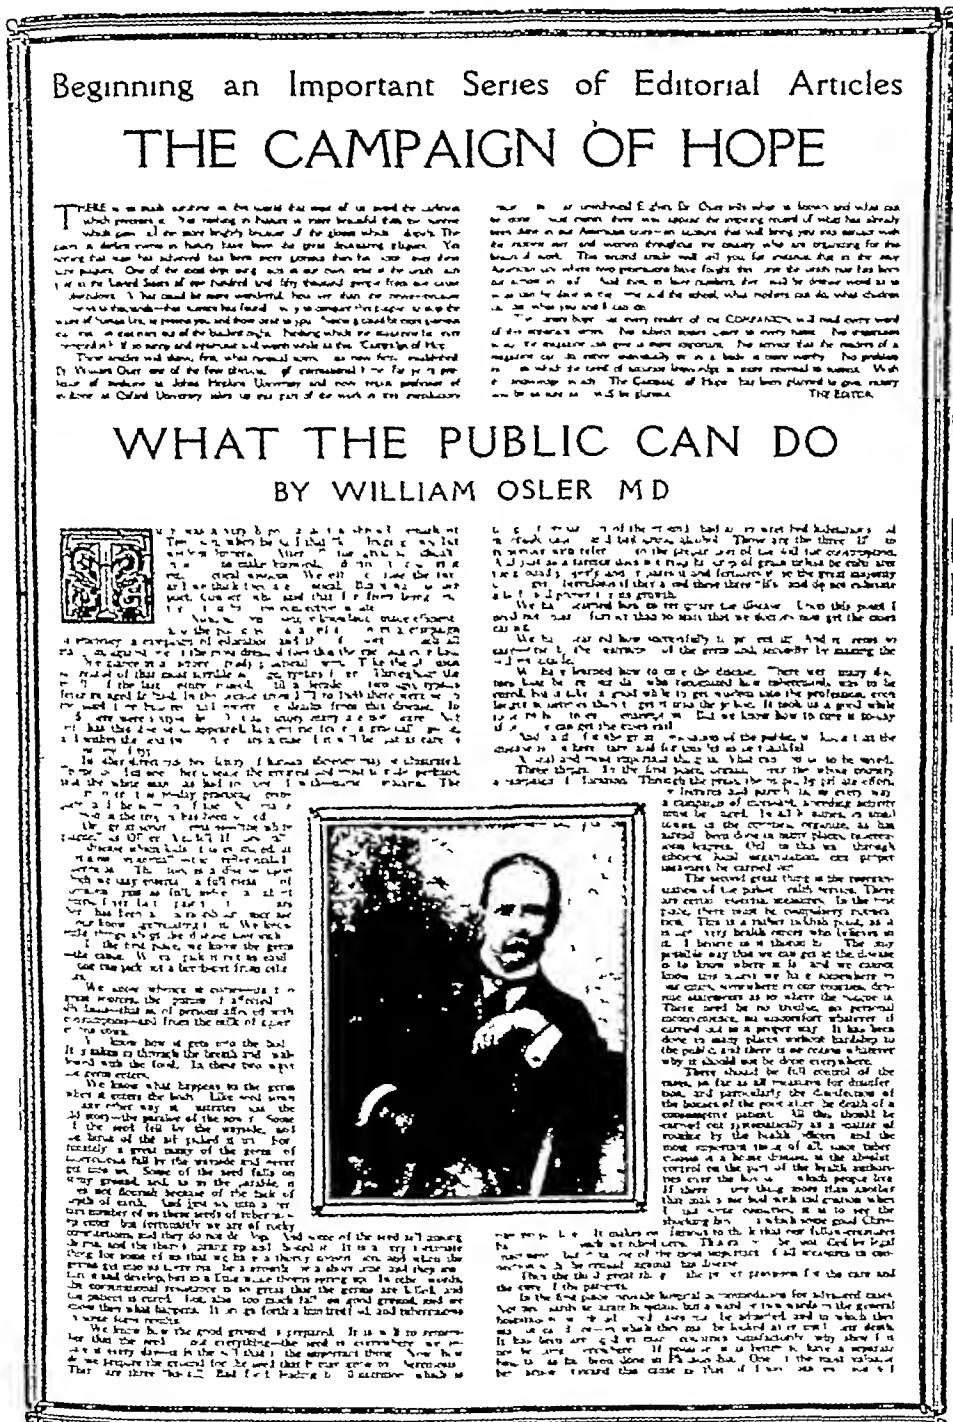

FIGURE 2 Title Page of Osler's Article in the February, 1910, Issue of the Woman's Home Companion (courtesy of the New York Public Library)

the hospital yard and in close proximity to the wards, with Stuart portraits at either end looking current literature pertinent to any subject that happened to be of immediate interest, and a good

many ancient books and periodicals that had accumulated with time. It was the pleasantest room in which to work that I have ever known.

Mrs. Myers presided over the library — always an awesome figure to the interns but an old friend of Dr. Osler's. On that morning, for once in our lives, we invaded her precincts with no hint of formality. Mrs. Myers and Dr. Osler greeted each other with distinct marks of affection, and then, as I recall it, Mrs. Myers got out for us to look at certain items dealing with bullous eruptions following the administration of iodide — perhaps Morrow's *Drug Eruptions*, which was first printed in 1887 and has for its colored frontispiece a bizarre example of iodism, or his article in the April and May, 1886 issues of the *Journal of Cutaneous and Venereal Diseases* on the same topic and reproducing the same drawing, or the more recent paper by Gottheil that had appeared in the *Journal of the American Medical Association* a few months previously. We could not find Hare's paper in the 1886 volume of the *New York Medical Record*, which described dynamic dilatation of the aorta, Dr. Osler mentioned this in connection, I presume, with our patient's endocarditis and anemia.

I cannot remember how long Dr. Osler's visit lasted. My recollection is that it was altogether too short and that it ended with a ceremonious parade to the Out Patient Department, headed by Dr. Pratt with Dr. Osler on his right, followed by Dr. Brigham and myself holding ourselves proudly erect, and ending with Dr. Parker, who ran ahead at every possible opportunity to open doors so that his seniors might encounter no physical inconvenience on their march.

Dr. Pratt tells me that a queer postscript should be added to this account of Dr. Osler's visit. Having deposited Dr. Osler and Dr. Pratt in a cab, the East Medical Service resumed its ordinary occupations. Dr. Osler wanted to go to the South Station, and Dr. Pratt accompanied him. Dr. Osler, apparently, disliked to hurry for trains, and so they got to the depot in ample time. They sat together in the stuffiness of a car that had been baked in the trainyard, and so they felt as though they were in a Turkish bath. Dr. Pratt asked Dr. Osler if he knew that one of his papers had been published in the *Woman's Home Companion*.

Dr. Osler replied that he had no knowledge of it. Dr. Pratt countered by citing the exact reference. And then Dr. Osler laughed and said, "That explains a great deal!"

A year before, Mr. Bok, editor of the *Ladies' Home Journal*, had asked Dr. Osler to write for the magazine a series of three articles on the American woman that would interest lay readers. Osler had given the matter considerable thought but finally refused, thinking that to do so was a little beneath the dignity of a Regius Professor of Medicine. However, in 1907 at a meeting in Ireland organized by the Countess of Aberdeen he had delivered a lecture, and this later was incorporated as an article in a booklet entitled *Ireland's Crusade Against Tuberculosis*, which had been privately published without copyright. Apparently an ingenious agent in this country had seen this article by Dr. Osler; had realized that he might use it without offending the law, had posed as Dr. Osler's American representative and had submitted it to the *Woman's Home Companion* as an original contribution. Dr. Osler told Dr. Pratt that until then he had never understood the letter of warm exposition that he had recently received from Mr. Bok.

It is interesting how vividly Dr. Osler and his personality always impressed people who came in contact with him. To those of us who saw him that morning at the Massachusetts General Hospital thirty-five years ago, his visit seems like yesterday, and each recalls something different from it. Dr. Pratt remembers the episode at the South Station, Mrs. Myers still smiles over the memory of the surprised group of house officers as they learned that she and Dr. Osler were old friends, Dr. Brigham remembers his charm, Dr. Parker remembers his demonstration of palpatory percussion in the recognition of hydrothorax, and I subscribe to an interest in medical history that has grown through his influence.

This, I suppose, is the essential secret of successful clinical teaching — so to endow one's associates that each acquires some personal gift in the way of knowledge or approach to clinical problems that is not usual and settled but is inventive and, by adding new rhyme and reason to what was routine, is enduring.

319 Longwood Avenue

MULTIPLE PERITONEAL AUTOTRANSPLANTATION OF SPLENIC TISSUE FOLLOWING TRAUMATIC RUPTURE OF THE SPLEEN*

Report of a Case in an Adult

RICHEY L. WAUGH, M.D.

BOSTON

THE purpose of this paper is to discuss multiple peritoneal autotransplantation of splenic tissue following traumatic rupture of the spleen and to present a summary of reported cases, together with the first report of a case occurring in an adult.

In the cases hitherto reported, all patients had in youth survived traumatic rupture of the spleen and later, either at reoperation or autopsy, numerous spleenlike nodules were found scattered over the various peritoneal surfaces, including the omentum, small and large intestine, diaphragm and pelvic cavity. Buchbinder and Lipkoff¹ consider the condition a clinical entity and suggest the use of the term "splenosis" to describe it. Despite the similarity, these spleenlike nodules should not be confused with accessory spleens or spleniculi, which are among the congenital anomalies most frequently found at autopsy.

It is apparent from a review of the literature that peritoneal autotransplantation of splenic tissue following traumatic rupture of the spleen is a rare condition. I have been able to find reports of only 15 cases, of which 9 are in the foreign literature and 6 in the American literature. An explanation for the small number of cases thus far reported is given by Hamrick and Bush.² These authors refer to the huge over-all mortality rate of between 90 and 100 per cent for traumatic rupture of the spleen and state that survivals are therefore relatively few in number. Consequently, the chances that such patients will come to abdominal surgical exploration or post-mortem examination are not very great. On the other hand, the actual occurrence of these splenic nodules in patients who have survived traumatic rupture of the spleen may be greater than has been reported.

The first known reference to the condition was that made by von Kuttner³ in 1910. He found multiple splenic nodules at autopsy in a patient four years after splenectomy following rupture of the spleen due to a gunshot wound of the abdomen. He, however, regarded these nodules as accessory spleens and not as implants of splenic tissue.

Faltin⁴ in 1911 was apparently the first to suggest that these splenic nodules were actually splenic implants. His patient was a nine-year-old boy who at the age of three had a ruptured spleen removed following an accident. During the next six years, he suffered with recurrent attacks of ab-

dominal pain, and an operation for chronic appendicitis was performed. At operation, multiple splenic nodules were found scattered throughout the abdominal cavity. One of these was removed, and on microscopic examination it showed the typical structure of spleen, including lymph follicles.

Von Stubenrauch⁵ in 1912 reported similar multiple nodules, ranging from the size of hemp seed to that of a pea and with the color of the spleen. These were found on the greater omentum, transverse mesocolon and small intestine in a patient operated on for ileus who ten months previously had received a splenectomy for traumatic rupture of the spleen. Von Stubenrauch concluded that the nodules were a result of so-called "seeding" by splenic pulp, which was scattered throughout the peritoneum at the time of the rupture of the spleen.

In the case reported by Lee⁶ in 1923, it was not stated whether the nodules were accessory spleens or implants. Von Küpperman⁷ in his report in 1926 called the nodules accessory spleens. Shaw and Shafi⁸ in their report in 1937 stated their belief that the nodules were true implants and not accessory spleens.

The 6 cases reported in the American literature include 2 cases reported by Jarcho and Andersen⁹ in 1939 and single cases reported by Buchbinder and Lipkoff¹ in 1939, Hamrick and Bush² in 1942, Krueger and Mast¹⁰ in 1942 and Boggs¹¹ in 1945. These reports contain excellent reviews or descriptions of this clinical entity and are well worth reading.

Buchbinder and Lipkoff¹ state that it has been shown experimentally that splenic tissue may be implanted in the peritoneum and readily survives transplantation. Von Stubenrauch¹² removed the spleen in several dogs and seeded the crushed splenic pulp throughout the peritoneal cavities. On sacrificing the dogs one to three months later, he was able to demonstrate the same picture that he had described in man. Marine and Manley¹³ in 1920 and Perla¹⁴ in 1936 showed the readiness with which autoplasmic splenic transplants grow in rabbits and albino rats, although these transplants were in the abdominal wall and not in the peritoneum.

Hamrick and Bush² state that Kreuter¹⁵ in 1920 experimentally excised the spleen in monkeys and smeared the splenic pulp over the peritoneum. Several weeks or months later the animals were sacrificed and splenic nodules were found widely dispersed over the peritoneal cavity. Jarcho and

*From the Surgical Service, United States Marine Hospital

†Medical director, United States Public Health Service, chief of the Surgical Service, United States Marine Hospital.

Andersen⁹ reviewed the literature and found cases of dogs that had had severe abdominal trauma, post-mortem examination revealing nodular implants of splenic tissue scattered throughout the abdominal cavities. These authors also stated that Griffin and Tizzoni¹⁶ as early as 1883 had noted that partial splenectomy in dogs was followed by the development of spleenlike nodules in the peritoneum.

In this connection, Boyd¹⁷ states that in some invertebrates the splenic tissue does not form a definite organ but is scattered beneath the serous coat of the gastrointestinal tract. He also states that some of the higher fishes exhibit splenic tissue divided into separate nodules. Clark¹⁸ states that in fishes, turtles and frogs the spleen exists as an elongated body developed in the mesentery parallel and in close proximity to the digestive tube along the upper, middle or lower part of the intestine.

It therefore appears that the autotransplantation of splenic tissue is comparable to the not infrequent finding of multiple accessory spleens or spleniculi. Moreover, it is apparent that both these conditions represent a reversion to the primitive or atavistic state, in which splenic tissue does not form a definite organ but is strewn throughout the subserous coat of the gastrointestinal tract.

According to the literature, autotransplantation of splenic tissue has been observed only in young patients who have suffered traumatic rupture of the normal spleen. Hamrick and Bush³ believe that the likelihood of success in grafting cells from splenic pulp on peritoneal surfaces is proportionate to the youthfulness of the normal spleen. These authors state that splenic-pulp cells of young persons probably have properties of increased viability or virulence much greater than those of similar cells in older persons.

The spreading or seeding of splenic-pulp cells on peritoneal surfaces is accomplished through the medium of the free blood present in the abdominal cavity following splenic rupture. After implantation, the nests of cells grow, and the nodules finally become encapsulated by fibrous tissue. On maturity, these splenic implants are found to have histologic structures not unlike that of normal spleen.

According to Hamrick and Bush,³ parenchymatous cells of no other abdominal organ exhibit similar characteristics except possibly those of the uterine endometrium. The surgeon should keep this in mind and be able to differentiate splenic implants and endometriomas.

No cases have been reported of autoplasmic transplantation of splenic tissue following splenectomy for pathologic conditions of the spleen. This is all the more interesting since it has been shown by Jarcho and Andersen⁹ that the number of these patients who survive and later come to reoperation or autopsy is much greater than that of patients

who survive splenectomy for traumatic rupture of the spleen.

Splenectomy for pathologic conditions of the spleen is usually accomplished without the spreading of splenic pulp over the peritoneal surfaces, but even if under unusual conditions such spreading occurred, the abnormal or diseased condition of splenic-pulp cells would probably hinder successful implantation. This view is also entertained by Shaw and Shafi,⁸ who state that the removal of diseased spleens is rarely if ever followed by implants, in spite of occasional tearing with some associated hemorrhage during the excision of a particularly large viscus.

Of the 15 cases reported as showing autoplasmic transplantation of splenic tissue, there are only 9 in which the age of the patient at the time of occurrence of the rupture of the spleen is stated (Table 1). The recorded ages ranged from three to fourteen years, with an average of ten years. In striking contrast is a patient who was thirty-two years of age at the time of the rupture of the spleen and splenectomy. A report of the case follows.

A M R, a 37-year-old housewife, was admitted on March 14, 1944, for treatment of menorrhagia and metrorrhagia of 5 months' duration. She had an abdominal operation at the age of 28, at which time the appendix and right ovary were removed. At 32 she suffered an abdominal injury in an automobile accident. Immediately after the injury she was taken to a hospital, and 1 hour after admission a splenectomy for traumatic rupture of the spleen was performed. The postoperative course was apparently uneventful.

Three months before the present admission, a cervical polyp was removed on account of menorrhagia and metrorrhagia. This operation, however, gave only temporary relief from bleeding, and the patient noticed an increasing amount of low-abdominal discomfort, fullness and pain. She had had three children, each full term at the time of delivery. The last pregnancy had occurred 12 years previously. Physical examination revealed a well developed but obese woman who did not appear acutely ill. The skin and mucous membranes of the lips were slightly pale. The temperature, pulse and respirations were normal. The blood pressure was 122/76. Except for the abdominal and pelvic (vaginal) findings, the examination was negative.

The abdomen was obese and flabby. There were two operative scars—one an oblique scar over the left upper quadrant, and the other a midline scar over the lower abdomen. There was moderate tenderness to palpation in both lower quadrants and a questionable mass in the suprapubic region slightly to the left of the midline. Vaginal examination revealed a cervix with a transverse laceration and a moderate degree of ectropion. There was also a moderate amount of erosion of the cervix, with an area of blanching, apparently at the site of the attachment of the previously removed cervical polyp. The body of the uterus was anterior in position and slightly enlarged. There were no masses or tenderness in the right fornix, but in the left fornix there was a slightly tender and movable mass about the size of a hen's egg. This mass was thought to be either a pedunculated uterine fibroid or an ovarian cyst.

The urine gave a + test for albumin but was otherwise normal. The blood examination revealed a moderate hypochromic anemia, with a red-cell count of 3,400,000, a hemoglobin of 70 per cent and a hematocrit of 34 per cent. The white-cell count was 6400, with 47 per cent lymphocytes, 52 per cent neutrophils and 1 per cent large mononuclears. The sedimentation rate was normal. Blood Kahn and Hinton tests were negative.

Under pontocaine spinal anesthesia, the abdomen was opened through a low midline incision. There were many peritoneal adhesions involving the peritoneum of the anterior abdominal wall, the body of the uterus, the left and

the sigmoid colon. The uterus was slightly irregular in contour and two or three times normal size. Both tubes and the right ovary were absent. The left ovary was cystic and three times normal size. Scattered over the serous surfaces of several loops of small bowel and the cecum were many small, reddish nodules varying in size from a pinhead to a small pea. The total number of nodules visualized in the limited abdominal wound exposure was about ten. These nodules were believed to be lymphoid tissue due to implantation of splenic pulp at the time of the previous rupture of the spleen and splenectomy. Further exploration of the abdomen by palpation revealed several stones in a flabby

healed by primary intention, and no vaginal discharge was present on pelvic examination a few days prior to discharge on the 20th postoperative day. The patient was advised to return later for cholecystectomy, but up to August 10, 1945 had not done so.

The pathological report, by Dr. T. F. Crahan, was as follows:

Grossly, there are two small encapsulated tumor masses closely apposed to each other, the larger measuring 2.5 mm. and the smaller 2 mm. in diameter (Figs. 1 and 2). On cut section the tumor masses have a slightly reddish color and

gall bladder and a mass of adhesions in the region of the splenic flexure of the colon.

The adhesions of the anterior abdominal wall, omentum, bowel and uterus were separated. A total hysterectomy was done, but the cystic left ovary, the larger cystic portions of which broke during the operative procedure, was not removed. Two small nodules were removed from the serous surface of the small intestine for pathological examination. Chromic catgut was used for ligatures and sutures, and plain catgut for the peritonealization of the pelvic cavity. Three grams of sulfanilamide was sprinkled in the pelvic cavity, and the abdomen was closed in layers with chromic catgut and Kaldernic sutures.

The postoperative course was uneventful, and the temperature the 5th postoperative day. The wound

are soft in consistence and the larger one shows several small, white follicles measuring less than 1 mm. in diameter. Microscopically, the two masses consist of small portions of splenic tissue completely surrounded by a fairly thick, dense fibrous capsule. Where they are apposed the fibrous capsule fuses. The larger mass shows malpighian corpuscles which have prominent arterioles. One of the follicles has a germinal center, with prominent hyperplasia of the reticulum cells. The pulp is extremely cellular, but in some areas definite sinusoids can be made out. Most of the sinusoids are empty, but some contain red blood cells. There is prominent hyperplasia of the sinus endothelial cells and pulp reticulum cells. There are scattered eosinophils and occasional groups of plasma cells. The capsule is focally infiltrated with lymphocytes and

plasma cells, chiefly perivascular. These vessels are mostly thin-walled capillaries. A definite hilus cannot be seen, but in the smaller of the two masses there is a small capil-

lary that seems to communicate with the pulp. The histopathological diagnosis is autoplasmic transplantation of splenic tissue.

This case is of unusual interest since the patient was thirty-two years of age at the time of the sple-

SUMMARY

The literature relative to peritoneal autotransplantation of splenic tissue following traumatic rupture of the spleen is reviewed briefly and discussed. Only 15 cases are reported in the literature. Of these, 9 cases are in the foreign literature and 6 cases in the American literature.

An additional case of autotransplantation of splenic tissue is reported and discussed. Its chief interest lies in the fact that the patient was thirty-two years old when splenic rupture occurred and splenectomy was performed.

These peritoneal splenic implants or nodules should not be confused with accessory spleens or spleniculi, which constitute one of the congenital anomalies most frequently found at autopsy, nor should they be confused with endometriomas.

The widespread location of these splenic implants or nodules bears a resemblance to the normal finding in some invertebrates, as well as in some of the higher fishes, in which splenic tissue does not

This shows two malpighian corpuscles, with lymphoid nodules and small arterial branches. Well formed trabeculae are not seen.

nectomy whereas in the previously reported cases the patients were children, the two oldest both being fourteen years of age. This is therefore the first

form a definite organ but is scattered beneath the serous coat of the gastrointestinal tract. This analogy therefore suggests that the condition can

be considered a reversion to the primitive or atavistic state

I am indebted to Passed Assistant Surgeon K M Endicott, Department of Pathology, National Institute of Health, United States Public Health Service, for his courtesy in making the microphotographs

GRANULOMA INGUINALE: A PROCTOLOGIC CONSIDERATION*

JOSEPH BERKOWITZ, M.D.†

BOSTON

GRANULOMA inguinale was first described as a clinical entity by Conyers and Daniels in 1896, although the etiologic factor was not discovered until 1905 by Donovan at the Madras General Hospital in India. This disease has been considered a venereal one owing to the fact that the lesion is found in most cases on the genitals or scrotum or in the inguinal region, and also because of its frequent association in the same patient with syphilis, chancroid or lymphogranuloma.

The principal pathologic manifestation is found in the skin. The lesion begins as a small papule or macule, which enlarges, ulcerates and spreads by contiguity. The ulceration is covered with pink raised granulations that bleed easily on trauma. Progress of the disease is slow. Over a period of months or years the skin becomes granulomatous and indurated. During this time the patient is ambulatory and in apparently good health, with no evidence of systemic reaction. The pathologic lesion is a chronic inflammatory granuloma characterized by a specific diagnostic cell, a large mononuclear, in the cytoplasm of which are numerous round or rod-like structures known as "Donovan bodies." The preponderance of opinion concerning the nature of these bodies favors the belief that they are gram-negative, nonmotile bacilli in a state of encapsulation.

The incidence of granuloma inguinale is highest in the Negro race and in warm climates. Direct smears from an ulceration or a biopsy specimen from a granulomatous mass are invaluable in the diagnosis. Pathologic entities that present a similar clinical picture and must therefore be ruled out are syphilis, chancroid, tuberculosis, lymphogranuloma and cancer. Specific diagnostic skin tests and laboratory procedures for excluding these diseases are readily available. A specific skin test for the diagnosis of granuloma inguinale has recently been elaborated, but this method has not yet been made generally available. Numerous forms of therapy have been employed, such as x-ray, fulguration and surgical excision, but the best results have been obtained with antimony preparations given intramuscularly.

CASE 1. A 26-year-old Negro soldier was admitted to the Surgical Service of this hospital on September 25, 1944, complaining of perianal pain. For 3 months prior to admission he had had pain on defecation, which lasted for 1 hour after completion of the movement. There was no anorectal bleeding, no anal discharge or protrusion, and no change in the size or character of the stool. For 1 week prior to admission there had been severe chafing about the anus, causing pain on walking and soreness on sitting. In 1935 the patient had had gonorrhea, which was treated. There was no history of a penile lesion or of injections for syphilis.

Physical examination disclosed a well-developed Negro walking in obvious pain. On both sides of the anus and directly opposed so as to make contact there were two areas of ulceration, each measuring 1.5 by 1.5 cm. The surfaces of these ulcerations were covered with raised red granulations. The underlying tissue felt nodular and indurated. There was no evidence of fissure, abscess or fistula. The sphincter tone was increased, and digital examination caused severe pain.

*From the Surgical Service, Lovell General Hospital, Fort Devens, Massachusetts.

†Junior assistant surgeon, Rectal Clinic, Boston Dispensary; assistant in rectal diseases, Brockton Hospital; formerly, surgeon in charge of rectal diseases, Lovell General Hospital, Fort Devens, Massachusetts.

The remainder of the examination was temporarily deferred, and it was suspected that the patient had an anal fissure.

Routine laboratory studies on admission were within normal limits. A Kahn test was negative. A routine Frei test was positive at 72 hours. The soldier was given hot sitz baths, with symptomatic relief. Further examination several days after admission was entirely within normal limits except for the indurated ulcerations. Sigmoidoscopy revealed no disease in the rectum or lower sigmoid. There was no evidence of anal fissure.

The ulcerations did not heal under palliative treatment, and the underlying induration persisted. On October 6, operation was performed. Minute abscess cavities were found beneath the ulcerations. On the left side of the anus these connected with each other and with a deep crypt at "9 o'clock" on the anorectal line. Fistulotomy was performed, with adequate shelving of the skin edges. The abscess cavities did not connect with the anal canal on the right side. These cavities were unroofed and packed with iodoform gauze. Sections of tissue were sent to the laboratory. Post-operative treatment consisted of hot sitz baths three times daily, a regular diet and mineral oil by mouth. Healing was slow.

The pathological report stated, in part, that the sub-epithelial layer was occupied by a large number of clear cells with vacuolated cytoplasm and small dark-staining nuclei (Fig 1). Some of these cells contained coccoid or rodlike Donovan bodies. The diagnosis was granuloma inguinale.

The patient was placed on intramuscular Fuadin* therapy, receiving 1.5 cc on the 1st day, 3.5 cc on the 2nd day, 5.0 cc on the 3rd day and 5.0 cc every third day for six doses —

FIGURE 1 Case 1

Photomicrograph of the biopsy specimen shows marked hyperplasia of the epithelium. Characteristic large clear cells occupy the papillae and upper layers of the corium. Occasionally these cells contain Donovan bodies.

a total of 40 cc. There was no reaction to the drug, and no pain resulted from the injections. The operative wounds closed steadily, leaving a soft healed scar with loss of normal skin pigment. Three weeks after the beginning of Fuadin therapy, the wounds were healed, and the patient was returned to duty.

In the above case the patient was suspected of having an anal fissure because of the typical history of severe pain associated with bowel movements.

*Sodium antimony-III bisacatechol disulphonate of sodium manufactured by the Winthrop Chemical Company, New York City.

and lasting for one hour following them. The two areas of ulceration were thought to be due to chafing arising from intensive military training. They were discrete and directly apposed and were covered with pink granulations such as are found in all healing wounds. The positive Frei test was significant in that it indicated the coexistence of lymphogranuloma inguinale. It would have been impossible to make the correct diagnosis from the appearance of the lesion alone, and except for the pathological report it would have been entirely missed. Had the diagnosis been suspected, it might have been confirmed sooner by smear or by biopsy.

CASE 2 A 24-year-old Negro soldier was admitted to the Surgical Service of this hospital on October 25, 1944, complaining of anal pain and purulent anal discharge. In 1934, he first noticed a small papule on the right side of the anus. This papule caused no discomfort but slowly increased in size until it was as large as a walnut. In 1942, an abscess developed at the site of the mass, and this was followed by a fistula. Some type of surgery was performed at a civilian hospital, but apparently the growth was left undisturbed. The patient felt well until May, 1944, at which time a night perianal abscess recurred. This was incised and drained. Drainage ceased for a short period but recurred in the following September, when the patient was admitted to an Army hospital and transferred to the Lovell General Hospital for further treatment and disposition. He denied having had gonorrhea but stated that he was taking "injections for his blood."

Physical examination disclosed a well-developed Negro in no distress. There was a large granulomatous mass measuring 5 by 3 cm just to the right of the anus. It extended medially to involve the anal canal and terminated laterally in two long, well-healed but indurated scars (Fig 2). The center of the

FIGURE 2 Case 2

Photograph of the granulomatous mass of ten years' duration.

mass was ulcerated and covered with a purulent secretion, beneath which were easily bleeding pink granulations. Digital examination was negative except for hard indurated tissue of the right anal wall. The sphincter tone was slightly diminished. There were slight internal hemorrhoids.

Routine laboratory studies were within normal limits. A Kahn test was negative. Consultation was held with the Venereal Disease Section, with a resultant diagnosis of early latent syphilis. A Frei test was negative at 72 hours. On October 26, a biopsy specimen was taken under local anesthesia.

The pathological diagnosis was chronic suppurative, non-specific inflammation. The degree of sphincter involvement could not be determined, but it was considered certain that extensive surgery would be required to eradicate the lesion.

The patient was returned to his unit on November 13 with a diagnosis of nonspecific granuloma, and it was requested that he be separated from the Service.

On December 14, a report was received from the Army Medical Museum on the biopsy material submitted to it, the diagnosis was granuloma inguinale. The patient was recalled at once to the hospital. He was complaining of a foul-smelling, purulent anal discharge. A biopsy was repeated. The resultant pathological report stated that here and there just beneath the epithelium there were marked edematous patches and a few large cells, with clear cytoplasm and round nuclei, some of which contained masses of rodlike or coccoid Donovan bodies deeply stained with blue (Fig 3). The diagnosis was granuloma inguinale.

Intramuscular Fuadin therapy was instituted as in Case 1. After conclusion of the course, the patient was allowed a rest

owing to the tendency to recurrence. Intramuscular Fuadin salvaged for military service a soldier who might otherwise have been lost to it.

SUMMARY

Granuloma inguinale is a chronic, progressive skin infection of the genitals, scrotum and inguinal regions. It occurs infrequently about the anus. Its

FIGURE 3 Case 2

This photomicrograph of a stained smear shows numerous intracellular oval (Donovan) bodies in the cytoplasm of a large macrophage.

of 1 week. There was no reaction to the drug. On December 16, the patient stated that he was having much less drainage. The lesion appeared unchanged, but within the following week the granuloma decreased considerably in size and showed much less surrounding induration. Drainage had practically ceased, and there were no complaints. On January 15, 1945, a second course of Fuadin was begun. It was completed on January 24, and the patient was returned to duty. Subsequently the granuloma disappeared entirely, leaving a small area of skin in which the normal black pigment was absent (Fig 4).

In this case granuloma inguinale had been present for approximately ten years, and the advanced granulomatous stage of the disease was well represented. Even though the diagnosis was suspected on admission, it was missed because of a poor section of tissue taken for biopsy. Two courses of Fuadin were given, a procedure that is recommended

FIGURE 4 Case 2

Photograph showing the healed lesion after two courses of Fuadin.

etiologic agent is a gram-negative, nonmotile bacillus identifiable by smear or biopsy in the state of encapsulation as a "Donovan body." The disease occurs primarily in Negroes.

Two cases are presented involving the region about the anus, one in an early ulcerating stage and the other in an advanced granulomatous stage. The response to Fuadin was excellent in both cases but was especially dramatic in the second case, in which there was a lesion of ten years' duration.

MEDICAL PROGRESS

RESEARCH IN PHYSICAL MEDICINE (Concluded)

ARTHUR L. WATKINS, M.D.*

BOSTON

ELECTROTHERAPY

Diathermy

Medical diathermy has been defined as the therapeutic use of heat generated in body tissues by a high-frequency current that has insufficient local intensity to produce temperatures high enough to destroy or injure tissues. These currents are applied locally by three methods: conventional long-wave diathermy with contact metal electrodes, short-wave diathermy with an electric field, air space or insulated electrodes being used, and short-wave diathermy with an electromagnetic field, a cable or coil being employed. Conventional or long-wave diathermy frequency is between 500,000 and 3,000,000 cycles per second, whereas short-wave diathermy frequencies are between 10,000,000 and 100,000,000 cycles. At the present time short-wave diathermy is used much more extensively than is long-wave diathermy, because of its ease of application, the somewhat less danger of burns and the more uniform temperature effects. The fundamental laws and concepts of alternating current phenomena on which short-wave diathermy technic is based have been well described in Osborne and Holmquest's³⁶ textbook on electrotherapy. A shorter summary has recently been written by Holmquest.³⁷ In summary, he states that in practice there are two methods of applying high-frequency power to tissue for treatment purposes — by means of the high-frequency field such as exists between plate electrodes, with or without an air space between electrodes and skin, and by means of the high-frequency magnetic field that is set up by the high-frequency current flowing through a coil, which is wound around the part to be treated or wound into a circular pad and placed over the tissues in which it is desired to generate heat.

Much investigative work has been done to determine the heating characteristics of these two methods. It has been shown that, with the high-frequency electric field, heating depends on the specific conductivity of the electrolyte exposed to the field and rises to a maximum for a certain conductivity. As the frequency of the field is increased, the conductivity at which maximal heating occurs also increases. It has been shown that there is a linear relation between frequency and specific con-

ductivity for maximal heating. With a frequency of 10 megacycles (wave lengths of 30 meters), maximal heating occurs in a sodium chloride solution having a specific conductivity of 5.4 for a concentration of 0.0045 gm.-mols per liter or 0.0263 gm per 100 cc of solution. Since for dilute solutions conductivity is proportional to concentration, one can readily determine the approximate concentration of sodium chloride solution into which the rate of heat production would be graded for various frequencies. The concentration of sodium chloride having the conductivity of blood plasma is 0.85 gm per 100 cc of solution. So that heat shall be produced predominantly in the vascular type of tissue where it is normally produced through energy metabolism, an extremely high frequency must be employed. It must not be inferred, however, that, the approximate specific conductivity of various organs of the body being known, frequencies can be selected to elevate the temperature of these organs without elevating the temperatures of other tissues and organs. Efficiency of the blood stream in dissipating heat and conveying it to other structures of the body tends to equalize temperatures and hence to prevent such specific heating.

Regarding the second method of applying high-frequency energy to the tissues, experiments have shown that the induction field generates heat in an electrolyte in direct proportion to the conductivity of the electrolyte. Such a field should produce heat dominantly in vascular tissue. Actual measurement of temperatures obtained in the deep tissues of living subjects has confirmed this theoretical deduction. From time to time claims are made for specific biologic and bactericidal effects of various frequencies. Careful investigators seem agreed, however, that the only demonstrable effects of short-wave diathermy are a production of heat and the physiologic responses that normally follow production of heat in tissue. Hence, the method of applying short-wave diathermy that develops heat primarily where oxidation produces it naturally in the human body, thereby inducing and maintaining active hyperemia and permitting the warmed circulating blood to convey heat to other tissues, seems to be the preferable manner of treatment of all conditions that might be benefited by such therapy.

The technic of application of short-wave diathermy has been well described in the standard textbooks

*Associate in medicine, Harvard Medical School; chief of physical medicine, Massachusetts General Hospital.

Regulation of dosage, however, is still empirical. It is necessary to rely on a comfortable heat sensation of the patient's skin in measuring doses, since the milliammeter on the apparatus does not measure the energy passing through the patient. Some experimental work has been done on the measurement of field strength, but these methods have not as yet been applied clinically.³⁸ Until further evidence is forthcoming, it is sufficient to say that the physiologic effect of diathermy is simply that of production of heat in the tissues.

Electrodiagnosis

The chief diagnostic function of specialists in physical medicine is appraisal of excitability of nerve and muscle by stimulation with appropriate electrical current. In considering the methods used for this purpose, the average physician or surgeon has been cognizant only of the test for the so-called "reaction of degeneration," as described by Erb. Recent developments in electrical engineering have made available for experimental and clinical use new instruments capable of producing currents of easily measured strength, duration and frequency of impulse. A number of laboratory and clinical studies based on these new methods have been published in the last few years. They are of particular interest at this time because of the frequent occurrence of peripheral-nerve injuries among war casualties.

In Erb's test, faradic and galvanic currents are used, and the preservation of normal responses to these currents serves to distinguish severe peripheral-nerve injuries from minor lesions, upper-motor-neuron disease and hysterical paralysis. The limitations of this test are, however, frequently overlooked. Of first importance is the fact that changes in the electrical reactions of paralyzed muscles do not appear, even after complete severance of the motor-nerve supply, before a minimum of four to five days and may not be completely developed for two weeks. Electrical tests are therefore of no diagnostic value unless time is allowed for these changes to occur. The responses of muscles that when tested for a sufficient length of time after injury indicate loss of conduction of the normal nerve impulse and degeneration of intramuscular nerve fibers have been described by Erb as the reaction of degeneration. Recently Pollock et al.³⁹ reinvestigated Erb's conclusions, making use of modern apparatus, and found that his description was essentially accurate. Denervated muscles do fail to respond to a faradic current when stimulated percutaneously. This is not absolutely true, however, for even completely denervated muscles respond to the faradic current if a sufficiently high voltage is used. It should be further pointed out that although only the faradic currents were used by Erb for this test it is more usual at present to employ a 60-cycle alternating, sinusoidal current, since it

is of proper frequency to produce a tetanic contraction in normal muscle and the separate impulses are of sufficiently short duration so that the denervated muscle does not respond with the voltage of current usually applied clinically. Consequently, a more accurate description of such a reaction would be to say that there is loss of response to a tetanizing current.

The type of response to stimulation by direct or galvanic current is of equal or even greater importance. Normal muscles respond to a direct-current impulse by a single quick twitch and rapid relaxation. Denervated muscles, on the other hand, with the same type of stimulus show a slow, wave-like contraction, which is frequently sustained to a lesser degree without complete relaxation so long as the current is applied. Pollock et al. describe this response as a tetanic contraction and emphasize its importance in following the state of innervation of muscle during various stages of degeneration and regeneration. Doupe⁴⁰ studied this response of denervated muscle to direct-current stimulation by means of simultaneous mechanical and action-potential recordings. He found that the sustained contraction was explained by repetitive excitation and described the phenomenon as galvanotonous, which is perhaps a better description than Pollock's, since clinically the contraction is not so great as that of a complete tetanus. Doupe also found that the temperature of the denervated muscle was below normal and that the slowness of contraction could be partially explained on this basis, since the prolonged excitation factor was also accentuated by cold, as was a hyperirritability to currents of long duration and threshold strength.

In addition to the sluggishness of contraction on galvanic stimulation, Erb mentioned a change in the response to positive and negative currents. Whereas the cathode-closing contracture is normally greater than the anode-closing contracture, during denervation the responses may be equal or occasionally reversed. Pollock et al.³⁹ and other observers⁴¹ have found that the threshold response to both cathode and anode stimuli may become equal during denervation but have never seen true reversal. Pollock has emphasized another feature of the degenerative reaction to direct-current stimulation — namely, hyperirritability. This may be more apparent than real, however, since the muscle contraction is increased because of prolonged excitation.

In addition to stimulating muscles directly with galvanic or tetanizing (faradic) current, it is also advisable to test conduction of nerve impulse by stimulating the nerve directly whenever possible, preferably above the site of the lesion. For this purpose either galvanic or faradic current may be used. The degenerated nerve does not transmit either current, and in this case responses are obtained only when the muscle is stimulated directly. Preservation of conduction along the nerve and of normal

faradic response when the testing is done sufficiently long after injury is accordingly of definite value in separating severe from minor injuries

These electrical tests described are, however, of little value in determining the first signs of recovery or of nerve regeneration, since it is generally accepted that voluntary return of function precedes return of faradic response. For accurate quantitative study of electrical excitability of nerves and muscles, the factors of current strength, duration and rate of increase of potential must be considered. Electrical generators are now available that enable one to control and measure stimulation. It has been found that when the development of current is essentially instantaneous, as with condenser discharges or square-wave impulses, there is a definite relation between the strength and the duration of impulse required to induce a barely perceptible standard or threshold contraction of the muscle. By stimulating muscles with currents of assorted strengths and durations, it is possible to plot the responses in the terms of a strength-duration curve that gives a graphic representation of the electrical excitability. Repeated determinations of such curves give fairly accurate qualitative measures of excitability, and at times changes may be detected in these curves that indicate beginning regeneration before it can be detected clinically.^{42, 43} Such a change may be either a shift in the total curve toward normality or the presence of a break in the curve, indicating fibers of different excitability, owing to the arrival in the muscle of some regenerated nerve fibers.⁴⁴

An arbitrary point on the strength-duration excitability curve has been designated as the chronaxie, or time factor of excitability. The first step in chronaximetry is to measure the voltage of current necessary to cause a liminal response when a unidirectional current of long duration is applied. This measurement is called the rheobase. The length of time that a current of twice the rheobase voltage must be applied to produce the same response is the chronaxie. Normally the chronaxie is extremely short, — 0.001 second or less, — but with denervation it becomes ten or even more than a hundred times greater. Chronaxie measurements are of greater quantitative value than are galvanic and faradic tests, but they do not offer so complete information as does determination of the whole strength-duration curve and are subject to more possibilities of error in the single determination as compared with the many points on the strength-duration curve.

Currents of various wave forms have also been employed to stimulate muscles for electrical diagnosis.⁴⁵ These may be in the shape of triangles, with a gradual increase of current to a peak and a similar decline, or progressive currents, or the wave form may be that of a true sine wave. The currents are used to measure another factor in

electrical excitability — namely, the power to accommodate to a slow change in potential. Because of this power, normal muscle does not respond to currents with a slow increase of potential except at high-current value. Denervated muscles, however, lose this characteristic and consequently respond to progressive currents of long duration and to extremely slow sinusoidal currents of low voltage. This change in accommodation, as indicated by the responses to progressive currents of long duration or to sinusoidal currents of low frequency, coincides with the changes in other measurements of excitability previously mentioned. Generators capable of producing progressive currents and low-frequency sine waves are to be found only in experimental laboratories, and consequently these tests do not have a wide clinical use.

All measurements of electrical excitability must be interpreted in proper relation to the time elapsed since injury or surgery. First, as previously mentioned, one or two weeks must elapse for the possible appearance of degeneration. Later, when one looks for regeneration, the maximum speed of recovery, approximately 4 millimeters a day, must be considered. Local factors, such as atrophy of the skin, edema and ischemia, may cause variations in the results. Perhaps most important of all is the skill, experience and diligence of the investigator in developing a standardized technic so that the results of one examination may be compared with those of another. The most valuable and accurate results are obtained by using a battery of electrodiagnostic tests, which are then repeated at stated intervals to determine the state of progress.

A new and entirely different method of electrodiagnosis, known as electromyography, makes use of the recording of small electrical potentials from muscles at rest or during voluntary contraction. Since these potentials are of extremely low voltage and short duration, a highly sensitive amplifier and recording system, such as the cathode-ray oscilloscope or amplifiers employed for recording brain potentials, must be employed. Bipolar electrodes are used, either percutaneously or by inserting a concentric needle into the muscle to be investigated. With these technics normal resting muscles give rise to no electrical discharges. During voluntary contraction, action potentials of a relatively high frequency and voltage and characteristic appearance are recorded.⁴⁶ These action potentials are, of course, not obtained in paralyzed muscles with complete denervation. Partially denervated muscles, on the other hand, may discharge scattered diphasic spikes, indicating some motor-unit activity, although no visible contraction is observable. The appearance of these spikes accordingly quickly differentiates a complete from a partial lesion.

In the case of complete degeneration, no action potentials are recordable, but if a proper type of amplifier is used, such as a cathode-ray oscillograph,

any spontaneous resting discharges of low voltage and duration may be recorded and identified as fibrillation of denervation, giving positive evidence of a complete lesion⁴⁷

Even with this sensitive type of instrument, there is a necessary long period of waiting before the slow process of nerve regeneration can be detected peripherally in the muscle. Electromyography is, however, of considerable value in picking up the first signs of neurotization of muscle in the form of spontaneous discharges of high voltage, indicating beginning motor-unit activity.

Another electrical aid in the measurement of nerve function is determination of skin resistance. For this purpose Richter and Katz⁴⁸ have described a simple dermatometer suitable for quickly mapping areas of high resistance to the passage of a direct current. These areas correspond to the distribution of sensory innervation of peripheral nerves, particularly the ulnar and median. The obvious advantage of such a test is that it is completely objective and does not require the co-operation of the patient. It is especially useful in cases of suspected malingering or hysteria. In my experience, the regeneration of sensory nerves can be detected much earlier by the usual clinical test of sensation than by measurement of the skin resistance. In some cases there is a lag of several months after sensation has returned before the skin resistance decreases to normal values.

Electrotherapy for Denervated Muscles

The value of electrical stimulation of a denervated muscle has frequently been debated in the literature⁴⁹⁻⁵². It is generally conceded, however, that stimulation of muscles during the first few weeks following denervation does not prevent the occurrence of denervation atrophy. The results in experiments that were continued for longer periods of time indicate that the rate of atrophy in the third and fourth weeks and later is considerably delayed by appropriate electrical stimulation of the denervated muscle⁵³. It has also been shown that although the rate of regeneration of the nerve is not affected by this treatment the return of voluntary muscle contraction is enhanced by electrotherapy and that the degree of fibrosis is lessened according to histologic examination. In the light of more recent studies, the negative effects of galvanic stimulation of denervated muscle have been explained as due to ineffectual or too infrequent stimulation. Daily treatment has been found to be more efficient than treatment on alternate days, and for optimum effect a stimulus should be chosen that will produce a maximal tension during contraction⁵⁴.

In view of the latest experimental work, it appears that the ordinary type of clinical muscle-stimulating apparatus is inadequate to achieve optimum therapeutic results. The rate of rise of

each impulse should be slow, and the frequency of impulses also should be slow, in the neighborhood of 10 to 25 per second, in order to cause maximum contraction of the denervated muscle with a minimum of current strength⁵⁵.

Recent experiments have also shown that the dangers of fatiguing muscles have been overemphasized in the past. Marked fatigue through artificial stimulation or forced exercise was found to have no deleterious effect on regeneration. It now seems apparent that maximum results in strengthening a muscle can be obtained only by producing a maximal degree of tension⁵⁴.

Ion Transfer (Iontophoresis)

Direct current may be used to drive certain medicinal electrolytes into tissues by the force of the polar reactions. The depth of penetration, however, is limited because of the far higher velocity and greater number of the tissue ions. The foreign ions introduced through the skin lose their electrical charge and are precipitated as soluble or insoluble compounds in the superficial tissues. The speed of circulation also serves to dilute the new ions quickly. In spite of these limitations, definite local and systemic effects can be produced by this method.

The drugs most widely used for the vasodilatory effect are histamine and mecholyl (acetyl-beta-methylcholine chloride). There are a great many clinical reports in the literature describing the use of these and other drugs in ion transfer. These have been summarized by Osborne⁵⁶. Very little fundamental research has been done, however. More work like that of Pereyra⁵⁷ is needed to clarify the subject. He studied microscopically the penetration of copper by iontophoresis in experimental animals, and found that the greatest depth effects were obtained when a solution such as aerosol MA was added to inhibit the binding of copper by tissue proteins. Quantitative studies by Molitor and Fernandez⁵⁸ provide data for safe dosage.

HYDROTHERAPY

The use of water for therapeutic purposes is well established. Certain physical characteristics are recognized to be of importance. Water is an extremely flexible therapeutic agent, being easily changed from a liquid to a gaseous or solid state within relatively narrow temperature ranges, which may be easily measured. It is an excellent heating or cooling medium because of its high conductivity. Since it has a high specific heat, large amounts of heat are necessary to increase its temperature, and hence it is an excellent cooling agent. Similarly, it liberates a large amount of heat when cooled, making it a good heating agent. The latent heat of vaporization is high, and the heat lost in insensible perspiration is consequently significant in the regulation of the body temperature. The evaporation of sweat accounts for the ability to lose heat rapidly. The

buoyant effect of water during immersion is taken advantage of in forms of muscle re-education with underwater exercises

The mechanical impact of water is also known to produce physiologic responses. The type of impact may be varied, as with showers, douches, bubbles and so forth, and sedative and stimulative effects can be observed clinically. The exact mechanism of these reactions has never been extensively investigated and is a field of research in physical medicine that needs to be further developed. The best known effects of water are those that are dependent on its temperature, and these have been discussed previously.

MECHANOTHERAPY

Massage

Knowledge of the physiologic effects of massage is rather limited. In actual practice, massage is usually preceded by application of heat and frequently followed by exercise. Improvement in circulation, relief of muscle spasm and an increase in joint range and strength of movement may be readily observed clinically. The exact role of massage in securing these effects has received little investigative study. Recent reviews on the physiology of massage^{59, 60} refer to studies done for the most part twenty to twenty-five years ago. Papers published since then have been almost exclusively clinical in nature, with the emphasis on technic. The early studies suggested that the twenty-four-hour excretion of nitrogen was increased on days that massage was administered. Diuresis and an increase in oxygen consumption and carbon dioxide production following general or abdominal massage have also been observed. More recent workers have failed to find any significant alteration of the metabolism in the normal subject, and at the present time it is generally believed that whatever metabolism changes may be produced by massage are secondary to the mechanical influence on the circulation of the parts concerned.

The effects of massage on circulation are more definite and are easy to demonstrate. Light stroking has been shown to produce an almost instantaneous, although transient, dilatation of the capillary vessels, with a more enduring effect when the pressure is heavier.⁶¹ Photographic studies of capillary circulation have also indicated changes in vessel walls that permit the passage of leukocytes. Some observers have found that the number of circulating red cells may also be increased by massage, although the exact mechanism is not explained.⁶² It is well known that lymphatic circulation is increased by massage and passive motions.^{63, 64}

It is inferred by clinical observation that massage affects the nervous system. Part of the dilatation of blood vessels is thought to be effected through sympathetic reflexes. Massage is probably most frequently employed for relief of pain resulting from

muscle spasm. Massage is also used for its general sedative effect and for its hypnagogic action. Massage is also said to have stimulative effects on the neuromuscular apparatus. It is certainly an adequate stimulus for exciting tendon reflexes in spastic patients. There is, however, an absence of studies that explain the mechanism of such effects, which are thought to be achieved through the action of massage on the nerves and muscles.

The practice of massage at present seems to be more of an art than a science. Physicians and technicians through years of experience may learn how to achieve the desired results, often by an individual technic. Prescription of massage consequently amounts to instructing the technician in the results desired, whether stimulative or sedative, and including instruction in the type of manipulation to be avoided. Considering that this method of treatment has been observed clinically to produce important beneficial effects in a large variety of conditions, it is unfortunate that more scientific knowledge concerning the mechanisms of its actions is not available.

Exercise

The subject of exercise has many ramifications into the fields of mechanics, biochemistry and physiology in health and disease. Attention is called to several recent reviews. Elkins⁶⁵ has emphasized that those prescribing therapeutic exercise should have a knowledge of the basic principles involved in muscular action. One of the primary factors relates to the mechanics of movement. The bones and joints make up a fairly intricate lever system, with changing forces depending on the angle of pull. Two other physical properties of muscle of considerable significance are its elasticity and its extensibility. Contractility of muscle varies with its length, and this has to be taken into consideration in performing re-education exercises. The control of muscle movement through the nervous system includes resting and postural tonus, as well as co-ordination and skillful activity. These topics have been briefly reviewed by Elkins, who also cites further references.

An aspect of locomotion of considerable importance is that of posture or body mechanics. From the point of view of the physician, there is a strong feeling, based on clinical evidence, that good posture is essential for health and that poor body mechanics may be responsible for a number of pathologic conditions. This point of view has been stressed for a number of years by Goldthwait, Brown, Swaim and Kuhns⁶⁶ and was recently summarized by Hansson.⁶⁷ That stresses and strains on joints and supporting structures may result from poor mechanics is fairly obvious. Physiologic studies on the effects of posture on the various systems of the body, however, have not produced evidence in defense of the medical opinions of the relation be-

between posture and disease, except in some extreme cases, such as scoliosis with compression on the thorax Hellebrandt and Franseen⁶⁸ have shown that compensatory mechanisms are developed in man that cancel the apparent mechanical disadvantage of the vertical stance in overcoming gravitational stresses Standing has been found to be cheap in terms of metabolic cost, and it has yet to be unequivocally demonstrated that improvement in body mechanics is associated with a significant decrease in exchange of energy⁶⁹ The circulatory system is probably most affected by posture The blood pressure decreases with the erect position, but there are many compensatory mechanisms that act to overcome the disparity between the size of the vascular bed during standing and the volume of flow Involuntary postural sway may be of considerable importance in stimulating reflex activities of vital centers located in the medulla, making circulatory adaptation more efficient Further studies of these compensatory mechanisms in health and disease are necessary to put the concept of what is correct posture on firm scientific ground

Another aspect of exercise that has lately aroused considerable interest is the problem of general physical fitness Much of the recent work is subject to rules of military secrecy and has therefore not yet been published Physical fitness has frequently been assessed by exercise tests, such as the step test or treadmills and bicycle ergometers During such periods of exercise observations are made of the circulation and respiration and of various aspects of blood chemistry Over a hundred papers on this subject have recently been reviewed by Taylor⁷⁰ Physical training has been found to increase exercise performance The physiologic results of training indicate that except for a small but consistent reduction in heart rate, changes in resting functions are either nonexistent or slight In submaximal work, mechanical efficiency is increased by training and physicochemical blood factors depart less from their resting values Coincident with substantial training, increments in maximal work output, maximal blood lactate, oxygen consumption and oxygen depth undergo increase Improvement in athletic type-fitness tests amounts to as much as 20 per cent Absolute muscle power has been shown to rise 30 per cent with training but is indefinitely maintained in the post-training period, whereas endurance depreciates rapidly to 50 per cent⁷¹

The problem of fatigue has stimulated considerable investigative work, including study of mental and emotional variables Neurocirculatory asthenia, the so-called "effort syndrome," is generally believed to be a psychoneurotic manifestation The general problem of muscular exercise and fatigue in disease has been well reviewed by Simonson and Enzer⁷² It is to be expected that the final analysis of the

large body of new information on exercise and fatigue that is being developed in relation to the recent war will place exercise therapy on a firm scientific basis

OCCUPATIONAL THERAPY

The medical profession in general is little acquainted with the potential value of occupational therapy Those clinically familiar with it have realized that muscular strength, co-ordination and adaptability of injured or diseased parts may be gained under the skilled direction of an occupational therapist It has been emphasized that mental as well as physical function is stimulated by such activities Psychiatrists have found occupational therapy to be an essential part of a therapeutic program, particularly for hospitalized patients Occupational therapy may also take the form of pre-vocational training as a part of adequate rehabilitation of injured persons

The medical literature, however, is extremely deficient in case studies and progress reports on occupational therapy Basic research, consisting of kinesiology studies and investigation of muscular-skeletal pathologic conditions, is also inadequate This sort of research is needed, together with studies aimed at evaluating certain crafts and shopwork activities, with the object of analyzing the motions required and their adaptability to applied kinesiology Familiarity with the present knowledge of technics and their effects should lead to further employment of this therapeutic agent and stimulate necessary studies

CASE 32191

PRESENTATION OF CASE

A seventeen-year-old schoolgirl entered the hospital because of fever and swelling of the ankles.

At the age of three years, following an attack of acute appendicitis, the patient developed migratory polyarthritis, a heart murmur and chorea. She was kept in bed for six months, then allowed up on slightly restricted activity. When she was seven years old there was a second bout of migratory polyarthritis, of unknown duration, without recurrence of chorea. There were no cardiovascular symptoms. After the second attack she continued in good health until six months before admission, when she twisted her right leg while swimming. Soon afterward the right leg became painful from the knee down. A chiropractor manipulated the leg and the pain disappeared. A week or two later she caught a "head cold," without a sore throat but associated with a temperature of 100°F and a two-day bout of sharp pain in the left upper quadrant of the abdomen. One month later (five months before admission) she was admitted to a hospital with fever that was immediately relieved by sulfadiazine and penicillin. Two months before admission she was sick again, this time at home in bed with fever, muscle aches, cough and swollen ankles. After three weeks she was able to walk

about but continued to have fever and ankle edema, which disappeared with rest. The night before admission she developed nausea, vomiting and a "stomach-ache," which persisted until she entered the hospital.

On physical examination there was a patchy erythema over the abdomen. The left border of the heart was 12 cm. to the left of the midline, with the maximal impulse in the fifth interspace. There was an apical systolic thrill. The mitral first sound was forceful, followed by a blowing Grade IV systolic murmur. The pulmonic second sound was greater than the aortic. The lungs were clear. The tip of the spleen was palpable and nontender, but the liver was not felt. There were two punctate, red, nontender areas on the cushion and tip of the left thumb.

The temperature was 99.6°F, the pulse 94, and the respirations 18. The blood pressure was 130 systolic, 80 diastolic.

The red-cell count was 3,470,000, with 82 gm of hemoglobin. The white-cell count was 21,700, with 82 per cent neutrophils. There was a slight trace of albumin in the urine, and the sediment contained 2 red cells and 25 white cells per high-power field. In the chest film the heart appeared normal except for enlargement of the left auricle posteriorly, best demonstrated fluoroscopically. The electrocardiogram was normal. The sedimentation rate was 145 mm. per minute (normal, less than 0.35 mm.).

During the first three hospital days the temperature steadily rose to 104°F and then spiked to 103 or 104 daily for a week. Blood cultures on the second and third days were negative, but five out of eight taken during the hospital stay were positive for an alpha-hemolytic streptococcus of the Lancefield Group A type. With the rise in fever an unproductive cough came on, which was accompanied by a "stitch" in the left side and was sometimes intensified by inspiration.

By the fourth day a ground-glass density had appeared in the chest film, which obliterated the left half of the diaphragm and the left costophrenic

sinus, as well as the left border of the heart and lower half of the left chest. The heart was displaced to the left (Fig 1). The cardiac pulsations were vigorous. The spleen was not palpable. A few alpha-hemolytic streptococci grew in the throat culture. On the ninth day a macular rash appeared on the arms and backs of the hands and knuckles. On the thirteenth day the temperature peak was 100°F, and it was never any higher from that time on. Signs of fluid in the left chest gradually disappeared. There was no fever from the fourteenth to the eighteenth day. About the eighteenth day

appeared over the left chest posteriorly. The white-cell count was 20,000, with 73 per cent neutrophils, 13 per cent lymphocytes and 14 per cent monocytes. The legs and thighs were normal. The temperature and pulse did not change.

On the following evening the patient suddenly clutched the left upper abdomen, vomited and began writhing and groaning. She was pale, cold and sweating. The breath sounds were equally good on both sides, but dullness persisted at the left base. The trachea was not displaced. The heart sounds were rapid and regular, and the mur-

FIGURE 1 *Roentgenogram of Lung.*

she began to complain of a dull constant ache in the muscles of the right thigh anteriorly, interrupted by occasional sharp pains in that region. On the twentieth day she complained of nausea, anorexia and periumbilical discomfort. The blood penicillin level on the twenty-fourth day was reported to be at least 0.06 but less than 0.24 units per cubic centimeter. The organism was inhibited in vitro by 0.06 units of penicillin per cubic centimeter. On the thirty-third hospital day the patient noticed aching pain in the left epigastrium and midepigastrium. It was similar to the attack four weeks previously, being constant and questionably aggravated by respiration. There was mild tenderness in the left upper quadrant. Dullness again

was unchanged. The abdomen was quite silent, but at one time fairly normal peristalsis was heard. The abdomen was negative for fluid, spasm and tenderness. The knee jerks were hypoactive but equal. The patient was using both arms and both legs equally well in twisting and turning. She responded to questions by grunting. Oxygen slightly improved the color of the skin. Death occurred thirty minutes after the onset of this acute episode.

DIFFERENTIAL DIAGNOSIS

DR ALFRED KRANES: There can be little doubt that this patient was suffering from subacute bacterial endocarditis, and I find it very difficult to

consider seriously any other disease in the differential diagnosis. We shall start the discussion then by assuming that this patient had subacute bacterial endocarditis. Certainly the presence of long-continued fever, anemia, muscle and joint pains and splenomegaly—at least I assume that the spleen was enlarged, although it was felt only on admission—occurring in a patient whose heart was previously damaged by two attacks of rheumatic fever is a reasonable background for assuming that the patient had bacterial endocarditis. When, in addition, five blood cultures are positive for alpha-hemolytic streptococci the diagnosis seems well-nigh conclusive. There are, to be sure, several findings frequently found in the disease that were not encountered here, but their absence argues little, if any, against it. No mention is made of clubbing of the fingers or of petechiae, unless one assumes that the two punctate hemorrhages on the left thumb were petechiae.

The disease probably began five or six months before admission, when she first complained of pain in the right lower leg, although that, of course, may have been a mechanical strain from swimming. On the other hand, people with bacterial endocarditis frequently have bizarre muscle and joint pains. The former are usually of embolic origin, resulting in muscle ischemia and pain. Certainly the disease was well advanced when she began to run a fever and complain of pain in the left upper quadrant, approximately five months before entry. As for the course of the disease, I see little worth commenting on at length. The episodes described are quite typical of bacterial endocarditis. Rashes are infrequent in the disease, but they do occur. Possibly it may have been a drug rash due either to penicillin or to something else, but rashes occur without the use of drugs in bacterial endocarditis. I think without much question that the repeated episodes of pain in the left upper quadrant can be ascribed to infarction of the spleen. It is such a common occurrence in the disease that I see no reason for trying to explain it on any other basis. The periumbilical pain, with nausea and anorexia, that persisted for a few days may have been due to an embolus in one of the small mesenteric vessels, too small to produce infarction of the bowel but large enough to produce a temporary disturbance of bowel function. The only findings worth commenting on are those in the left thorax. I think that it would be helpful to look at the x-ray films.

DR JAMES R. LINGLEY This is a film taken on admission. The heart shadow is not appreciably enlarged in the transverse diameter, but it is enlarged across the base, owing to enlargement of the left auricle. It has a rather typical mitral configuration. The lungs were clear at that time.

DR. KRANES Have you any hesitation in saying that it was a rheumatic heart?

DR. LINGLEY That was our interpretation.

DR. KRANES That is not quite clear from the record.

DR. LINGLEY I remember it particularly because I interpreted the films myself. This film was taken four days later and one month before death and shows a marked change on the left. There is extensive density in the left lower lung field, with elevation of the diaphragm and displacement of the heart shadow to the left. The appearance is consistent with atelectasis of the left lower lobe, and there apparently is some fluid along the axillary border. The amount of atelectasis is not inconsistent with an infarct.

DR. KRANES Can a high diaphragm itself produce that degree of atelectasis?

DR. LINGLEY I do not believe so. I think that the elevation of the diaphragm is due to a collapse of the left lower lobe.

DR. KRANES Before seeing the films I had visualized a somewhat different state of affairs. I had the impression, from the abstract, that most of the findings in the chest were explained by fluid, despite the statement that the heart had been displaced to the left. Consequently I had postulated that what was taking place was probably a large infarction of the superior pole of the spleen, as a result of which an inflammatory process had taken place, the spleen becoming adherent to the under surface of the diaphragm, with consequent irritation and outpouring of fluid into the pleural cavity. According to Dr. Lingley, however, this looks more like a process going on within the lung itself. If that is so, one would have to assume that the infarction was pulmonary rather than splenic. I hesitate to make that diagnosis since in doing so one has to assume that the vegetations were on the right side of the heart—a rare occurrence in bacterial endocarditis. The overwhelming majority of vegetations occur either on the mitral or aortic valve, or both. Only infrequently are they found on the tricuspid or pulmonary valve from which pulmonary emboli would originate.

This raises another interesting question. Did this patient have rheumatic heart disease or are the findings described here compatible with a congenital heart of some sort? I think that one has a right to raise that question, despite the history of two attacks of rheumatic fever. The first attack, which occurred at the age of three and during which time the heart murmur was heard, may be seriously questioned. Although rheumatic fever does occur in children below the age of four or five it is extremely rare. When one hears a heart murmur at that age, even in the presence of chorea, one has a right to ask whether the murmur might not have been present previously. There is no way of answering that question in this case. The type of congenital lesion that might explain this would be, of course, a patent interventricular septum, and the findings on admission of a thrill and a loud

systolic murmur are not inconsistent with such a diagnosis. I am, however, inclined to believe the history and to accept at its face value the statement that two attacks of rheumatic fever occurred, particularly since the configuration of the heart, as pointed out by Dr. Lingley, was also consistent with rheumatic heart disease.

The real problem in this case centers around the nature of the terminal episode. What caused this patient's death within a period of thirty minutes after she had been apparently progressing quite satisfactorily? The usual causes of sudden death in patients with bacterial endocarditis are the result of emboli to various vital organs—the brain, the heart or one of the viscera. So far as the brain is concerned, there certainly is no evidence in this terminal picture on which to incriminate the central nervous system, although it is the most frequent site of embolism. They have been extremely explicit in telling us that the patient moved her arms and legs while thrashing around in bed.

So far as the heart is concerned it is somewhat more difficult to exclude a massive myocardial infarct as a result of occlusion of one of the coronary arteries by a vegetation. It is not an infrequent cause of sudden death in cases of bacterial endocarditis and is due either to large vegetations growing over the aortic valve and occluding one of the coronary mouths or to the breaking off of a small vegetation, which lodges inside a coronary artery. Although it is a perfectly possible situation that cannot be excluded, it is rather unlikely because of the clinical findings. The description of this episode does not sound like an attack of acute myocardial infarction. Although it does not specifically state so, I am assuming that the patient had a good deal of pain in the left upper quadrant. The only evidence is that she grasped that area. The record does not state that she had pain, but it is reasonable to infer that there must have been a good deal of pain. Pain localized to the left upper quadrant seems to me unusual in a patient dying of myocardial infarction. If that were the case, one would expect to hear some alteration in the quality of the heart sounds, but they are described as unchanged, aside from an increase in rate. I think that a large myocardial infarct from an occluded coronary vessel is not probable, although I cannot rule it out.

Nor can I exclude a pulmonary embolus. If these previous findings in the chest were due to pulmonary infarcts, the terminal event might also have been due to the same process, but again the clinical picture is not that of a pulmonary embolus. One learns, however, in these exercises that typical clinical pictures are rare. She was described as pale and sweating rather than cyanotic. Furthermore, after a month of therapy with penicillin, if any vegetations did persist, one would not expect them to be large. The pulmonary infarcts that occur with bacterial endocarditis are likely to be

small, not the massive ones that cause death. One must, of course, consider the possibility that the embolus arose from thrombi in a leg vein, but there was no evidence of phlebitis except for the pain in the right leg several weeks earlier. I am rather inclined to believe that this patient did not have a pulmonary embolus, although clinically such a diagnosis is somewhat more acceptable than is myocardial infarction.

Another unusual and rare cause of sudden death in bacterial endocarditis is rupture of an aortic valve due to ulceration secondary to the vegetative process. I do not see how we can make that diagnosis here. The usual picture is that of rapidly progressive congestive heart failure, as well as the occurrence of a diastolic murmur that had not previously been present. We are specifically told that no change occurred in the pre-existing murmurs, and under the circumstances a ruptured aortic cusp is extremely improbable.

Could this patient have had an embolus to one of the abdominal viscera? If so, to what viscus? I do not see how an embolus to any of the abdominal viscera usually involved could produce death in thirty minutes. It takes time for infarction of the bowel and perforation with peritonitis to occur. It would be a most unusual state of affairs for a patient with mesenteric thrombosis to die within so short a period. Had it taken place over a period of hours, I should consider it much more seriously.

One would like, of course, to tie up this terminal episode with what had gone before. The patient had complained several times of discomfort in the left upper quadrant, which I assume was due to infarction of the spleen. At the end she suddenly grasped the left upper quadrant, apparently in great pain. I should like to believe that the terminal episode had something to do with the spleen. If so, the only conceivable explanation that I can offer is a spontaneous rupture of the spleen. Certainly the clinical picture as given here fits that much better than anything else I can think of. I hesitate to mention it because it is so rare. It occurs in a variety of septic spleens and in leukemia. Although I am not aware of its having been described in bacterial endocarditis, I know that it has been reported in many other conditions in which the spleen has been septic or infarcted, such as in malaria. Certainly, if this were a case of malaria and the patient suddenly grasped the left upper quadrant and died in thirty minutes with signs and symptoms of shock or hemorrhage, there would be no doubt in one's mind that the patient died of a ruptured spleen. Possibly I have become sensitized to this condition after having seen one case of malaria with a ruptured spleen and a picture not dissimilar to this. It seems to me that the diagnosis of the terminal event lies essentially between pulmonary embolus, which is far more frequent but does not fit the clinical picture too well, and spontaneous

rupture of the spleen, which is rare but fits the description here better than anything else I can think of. So I shall suggest that

DR F DENNETTE ADAMS Could the lung picture have been due to ordinary collapse of the lung without infarction in a sick patient lying in bed?

DR KRANES As the terminal event?

DR ADAMS No

DR LINGLEY It would be unusual to have that amount of fluid with collapse

DR. DONALD S KING The symptoms of writhing and groaning interest me. I have never seen that picture with a pulmonary embolus. The patient with a pulmonary embolus is usually quiet and does not writhe. I think Dr Kranes's suggestion that it was due to something else is a good one.

DR BENJAMIN CASTLEMAN Dr FitzHugh, I believe that you saw this patient. Will you say a word or two about your impression?

DR GREENE FITZHUGH First, I want to congratulate Dr Kranes on his excellent discussion. We thought that the symptoms in the left upper quadrant were due to infarction of the spleen or left

FIGURE 2 Photomicrograph of a Healing Bacterial Vegetation on the Mitral Valve

The dark-staining masses are clumps of cocci. Note the giant cell

kidney. The spleen was felt by only one person out of the six or eight who examined her. I was not that one. We believed that she was having repeated infarcts. The lungs were negative.

CLINICAL DIAGNOSES

Subacute bacterial endocarditis
Pulmonary embolus

DR KRANES'S DIAGNOSES

Subacute bacterial endocarditis
Splenic infarcts
Spontaneous rupture of spleen

ANATOMICAL DIAGNOSES

Subacute bacterial endocarditis mitral valve
Splenic infarcts, with rupture of spleen
Hemoperitoneum
Rheumatic heart disease, with mitral and aortic involvement
Embolitic nephritis, healing
Hydrothorax, left
Pulmonary atelectasis left lower lobe
Gluteal abscesses

PATHOLOGICAL DISCUSSION

DR CASTLEMAN At autopsy, when the abdominal cavity was opened, we found the entire left side filled with clotted blood. The blood was present

FIGURE 3 Photomicrograph Showing a Healing Process in the Upper Portion of a Glomerulus

in both the lateral gutter and the pelvis, but it was particularly concentrated in the region of the hilus of the spleen. There were infarcts in both the upper and the lower poles of the spleen. Between them, just anterior to the hilus, was a tear with a reddish-black clot over it. The spleen was about three to four times normal in size, weighing 640 gm. Most of the enlargement was probably due to the large amount of intrasplenic hemorrhage, which formed a clot measuring about 10 cm in diameter. This hemorrhage was adjacent to both the upper and lower infarcts, we were not certain that the hemorrhage began in either of these infarcts, although it probably did. There was no evidence of infarction in the central portion of the spleen.

The heart was only slightly hypertrophied. There was slight thickening of the aortic valve, but no evidence of bacterial endocarditis. The mitral valve was markedly thickened, and on one of the leaflets was a hard vegetation 2 or 3 mm in diameter, superimposed on which was a thin layer of friable

tissue. Clumps of organisms could be seen microscopically within the vegetation, with a lot of scarring and granulation tissue around them. In one granulating area we found a giant cell of the foreign-

was fairly adherent to the diaphragm. Dr. Kranes's initial hypothesis was therefore correct. The infarct had broken down and had irritated the diaphragm and pleura, thus producing pleural effusion.

FIGURE 4 Photomicrograph Showing the Necrosis and Foreign-Body Giant-Cell Reaction at the Site of the Injection of Penicillin in Beeswax and Peanut Oil

body type (Fig 2). The process, therefore, was almost healed but still contained many organisms.

The kidney showed evidence of a healing embolic nephritis. About one fifth or one sixth of the glomeruli were involved, in some there was complete involvement, but in most of them only a small portion of the tuft was infarcted (Fig 3). There was no evidence of an acute embolic nephritis; all the lesions were healing or healed, which is fairly good evidence that no further emboli were getting into the kidney. This patient had been receiving penicillin in beeswax and peanut oil, and a section of the buttocks, where the injections had been given, showed fairly extensive muscle degeneration, surrounded by a foreign-body reaction (Fig 4). I should think that this might have caused a lot of pain.

DR. KRANES: Was there any evidence of pulmonary infarcts?

DR. CASTLEMAN: In the left lower chest there was 200 cc. of clear, straw-colored fluid, with surrounding atelectasis of the left lower lobe. There was no evidence of infarction. The splenic infarct in the upper pole was cystic, and before sectioning felt as if it might have been an abscess. This had extended to the capsule of the spleen and

and atelectasis. The pleural effusion had disappeared for the most part by the time of autopsy. This last x-ray (Fig 1) was taken one month before death.

CASE 32192

PRESENTATION OF CASE

First admission. A fifty-eight-year-old housewife entered the hospital during an acute asthmatic attack.

About twenty-five years before admission the patient had her first attack of bronchial asthma. There was no known precipitating event. Subsequently she had mild intermittent attacks for three or four years. Then she inhaled vapors from boiling hemlock branches and had a complete remission for fifteen years. Four years before admission, at the age of fifty-four, following an emotional upset she was again stricken by an asthmatic attack. After that there were infrequent mild attacks until ten months before admission, when she had an attack severe enough to require treatment by a doctor. Her next severe attack brought her to the hospital.

On physical examination there was labored, wheezing respiration, with a prolonged expiratory phase. The anteroposterior diameter of the chest was increased. The lung fields were hyper-resonant, the diaphragm was depressed, and expansion diminished.

The temperature was 99°F, the pulse 110, and the respirations 22. The blood pressure was 160 systolic, 110 diastolic.

The red-cell count was 5,360,000, and there were 15 gm of hemoglobin. The white-cell count was 10,950, with 62 per cent neutrophils and 9 per cent eosinophils. The urine was normal. By x-ray examination the lung fields were bright. The diaphragm was low, and its excursion limited. The pulmonary markings were prominent throughout the chest, particularly at the bases. The heart was slightly enlarged to the left. Orris powder caused a 2-cm skin wheal, with a 1-cm erythematous border. Chicken feathers, ragweed and goose feathers also gave positive, although smaller, skin reactions.

The asthmatic attack responded to aminophylline, ephedrine and sedatives. The patient was discharged on the third hospital day.

Final admission (twenty-eight months later). Within the next two years there were seven brief admissions for asthma. All were completely or partially relieved by aminophylline, chloral hydrate and potassium iodide. Between admissions the patient was sometimes free of asthma, but she often had attacks that required adrenalin injections by a doctor or visiting nurse. There was a general trend toward chronic asthma, with gradual shortening of the periods of good health. After several of the admissions she spent one or two weeks in a nursing home. During her third admission she had a pneumonia affecting the right lower lobe, and a Type 3 pneumococcus was isolated from the sputum. At the end of the two-year period she carried on fairly comfortably by taking potassium iodide, aminophylline and ephedrine daily. There was never any evidence of heart failure, and an electrocardiogram on the next to the last admission was normal. The chest films showed little change in the two years.

Two weeks before the final admission she began to have more frequent attacks, particularly at night. They gradually became worse, until finally nothing relieved them.

Physical examination revealed slight cyanosis and moderate respiratory distress. Expiratory wheezes and rhonchi were heard over both lung fields but were more numerous on the left. The heart sounds were faint. The pulmonic second sound was greater than the aortic. The neck veins were not distended. There was no enlargement or tenderness of the liver, nor any ankle edema.

Twenty-four hours after admission the patient's condition was considerably improved under the usual treatment of 10 cc of aminophylline intravenously. While dressing to go home, she suddenly

became much worse. When examined a few minutes later, she was seated half dressed in a chair, doubled forward and breathing in short grunts. The usual asthmatic rales were heard at the right base posteriorly, but the respiratory exchange was very shallow. She was extremely cyanotic. Oxygen was given by mask, and artificial respiration was started as the breathing was reduced to an occasional gasp. There were several convulsive movements of the face, and she died ten minutes after the onset of the attack.

DIFFERENTIAL DIAGNOSIS

DR J EVARTS GREENE. Here is another case in which the cause of sudden death is the chief problem. We know that this woman had asthma and that it began twenty-five years before admission, at the age of thirty-three years. She had a little trouble for three or four years, and then the inhalation of hemlock vapor "cured" her. At the age of fifty-four, following an emotional upset, she again developed asthma. This brings up the possibility of a reflex or nervous factor in the precipitation of asthmatic attacks, and apparently this patient did have asthma in response to emotional stimuli.

Physical examination on the first admission gave good evidence of emphysema. The anteroposterior diameter of the chest was increased, the lung fields were hyper-resonant, the diaphragm was depressed, and its expansion was diminished. At that time the blood pressure was 160 systolic, 110 diastolic, which indicates that she probably had some hypertension.

The laboratory work did not show a marked increase of red cells or hemoglobin, so that it does not appear that she had any compensatory polycythemia. The x-ray film of the chest was said to show prominent pulmonary markings, particularly at the bases. The heart was slightly enlarged to the left, and there was a question whether she had pulmonary fibrosis. The patient did obtain relief by coming to the hospital on frequent occasions. It is possible that she was sensitive to some dust at home, which was avoided when she came to the hospital.

She had Type 3 pneumococcus pneumonia on one of her admissions. In our experience pneumococcal pneumonia is infrequent in patients with bronchial asthma. Of course, it can and does happen.

Two weeks before the final admission, the attacks increased in frequency and severity. On entry she was slightly cyanotic and musical rales and rhonchi were heard, more numerous on the left side than on the right. There was no evidence of myocardial failure; the neck veins were not distended and there was no enlargement of the liver or edema of the ankles. Apparently no moist rales were heard in the lungs. Presumably no x-ray film of the chest was taken at the onset of the terminal event, which only lasted ten minutes. Perhaps we should see the x-ray films.

DR. JAMES R. LINGLEY We have films over a two-year period, which show practically the same thing, except for the pneumonia. This is the first film, and it shows marked emphysema on both sides, with slight enlargement of the heart on the left. This is the last film, taken two years later, and it shows practically no change.

DR. GREENE Is there any appreciable sign of fibrosis?

DR. LINGLEY There may be a moderate degree.

DR. GREENE Then we come to the terminal event, which lasted only ten or fifteen minutes. The cause of sudden death is difficult to determine. I do not feel entirely satisfied with any of the various possibilities that I think should be considered. The first is that this patient died simply of a bad attack of asthma, which came on for no obvious reason just as she was getting dressed to go home. Perhaps it was in response to the exertion of getting dressed, or perhaps there was an emotional basis in the thought of going home. Asthmatic attacks do develop suddenly under these conditions. On the other hand, a ten-minute period is extremely short for death from an attack of bronchial asthma, and apparently she had been fairly comfortable just before the terminal event. Cases have been described in which asthma led to death within an extremely short period of time.¹ I believe it is possible that this patient's death was based purely on asthma, although it is unlikely.

The second possibility that comes to mind is a massive pulmonary embolus. I cannot recall having seen fatal pulmonary embolism in patients with asthma. We have no evidence from the history that there was any focus from which a pulmonary embolus might have come, but there is no reason why she may not have had a large embolus from a femoral or pelvic vein.

A third possibility, coronary thrombosis, seems quite unlikely. There is no mention that the patient had pain. The main complaints seem to have been dyspnea and cyanosis, so that although coronary thrombosis is possible, I believe that it is unlikely.

A fourth possibility is spontaneous pneumothorax. A few cases have been described in which asthmatic patients have had spontaneous pneumothorax followed by death,² but they are exceedingly rare. If such had occurred one would expect the patient to have had a good deal of pain, and there should have been typical signs of pneumothorax, with shifting of the heart and the mediastinum to the opposite side. On the other hand, the description of the examination of the chest during the terminal episode is not at all complete, and we cannot be quite sure about the shift of the mediastinum, or whether the intercostal spaces were larger on the one side than on the other.

The fifth and final possibility is massive collapse of the lung, which may be due to sudden obstruction

of the bronchi, to pulmonary infarction, to infection, of which we have no evidence, to an allergic cause or to nervous stimuli. Again there should have been, unless the massive collapse was bilateral, shift of the mediastinum, although this time toward the affected side, and a high diaphragm on the same side.

Finally, I might mention just for the sake of completeness the fact that some patients with asthma die following the administration of morphine. We have no indication that this patient had been given morphine. Death has also been due to periarteritis nodosa and asthma, but there is no evidence that this patient had periarteritis nodosa.

Granted that none of the explanations that I have offered for the terminal episode are entirely satisfactory, I favor a diagnosis of pulmonary embolism in this case, particularly because of the sudden onset and the rapid course of the terminus, but also because the patient was making some exertion in the act of getting dressed, perhaps the first she had made in some hours, which could have led to the dislodging of a large thrombus in a femoral or pelvic vein.

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN The autopsy findings in the usual case of a patient dying of an asthmatic paroxysm have often been described at these exercises by Dr. Mallory, and we have had 18 such cases out of a series of autopsies on 50 asthmatic patients. The lungs are usually ballooned and meet in the midline, covering the heart. They do not collapse when the chest plate is removed. On section, the bronchi are filled with mucous plugs, usually in the medium-sized bronchi, although occasionally in the large bronchi. The walls of the bronchi are thickened, and the mucous glands are hypertrophied. The basement membrane is thickened, and there is lymphocytic and eosinophilic cellular infiltration of the walls. Autopsy of this patient

On physical examination there was labored, wheezing respiration, with a prolonged expiratory phase. The anteroposterior diameter of the chest was increased. The lung fields were hyper-resonant, the diaphragm was depressed, and expansion diminished.

The temperature was 99°F, the pulse 110, and the respirations 22. The blood pressure was 160 systolic, 110 diastolic.

The red-cell count was 5,360,000, and there were 15 gm of hemoglobin. The white-cell count was 10,950, with 62 per cent neutrophils and 9 per cent eosinophils. The urine was normal. By x-ray examination the lung fields were bright. The diaphragm was low, and its excursion limited. The pulmonary markings were prominent throughout the chest, particularly at the bases. The heart was slightly enlarged to the left. Orris powder caused a 2-cm skin wheal, with a 1-cm erythematous border. Chicken feathers, ragweed and goose feathers also gave positive, although smaller, skin reactions.

The asthmatic attack responded to aminophylline, ephedrine and sedatives. The patient was discharged on the third hospital day.

Final admission (twenty-eight months later). Within the next two years there were seven brief admissions for asthma. All were completely or partially relieved by aminophylline, chloral hydrate and potassium iodide. Between admissions the patient was sometimes free of asthma, but she often had attacks that required adrenalin injections by a doctor or visiting nurse. There was a general trend toward chronic asthma, with gradual shortening of the periods of good health. After several of the admissions she spent one or two weeks in a nursing home. During her third admission she had a pneumonia affecting the right lower lobe, and a Type 3 pneumococcus was isolated from the sputum. At the end of the two-year period she carried on fairly comfortably by taking potassium iodide, aminophylline and ephedrine daily. There was never any evidence of heart failure, and an electrocardiogram on the next to the last admission was normal. The chest films showed little change in the two years.

Two weeks before the final admission she began to have more frequent attacks, particularly at night. They gradually became worse, until finally nothing relieved them.

Physical examination revealed slight cyanosis and moderate respiratory distress. Expiratory wheezes and rhonchi were heard over both lung fields but were more numerous on the left. The heart sounds were faint. The pulmonic second sound was greater than the aortic. The neck veins were not distended. There was no enlargement or tenderness of the liver, nor any ankle edema.

Twenty-four hours after admission the patient's condition was considerably improved under the usual treatment of 10 cc of aminophylline intravenously. While dressing to go home, she suddenly

became much worse. When examined a few minutes later, she was seated half dressed in a chair, doubled forward and breathing in short grunts. The usual asthmatic rales were heard at the right base posteriorly, but the respiratory exchange was very shallow. She was extremely cyanotic. Oxygen was given by mask, and artificial respiration was started as the breathing was reduced to an occasional gasp. There were several convulsive movements of the face, and she died ten minutes after the onset of the attack.

COMING ANNUAL MEETING

FOLLOWING an enforced hiatus of two years the one hundred and sixty-fifth anniversary of the Massachusetts Medical Society will be held at the Hotel Statler, Boston, on May 21, 22 and 23, the program of the meeting appears elsewhere in this issue of the *Journal*.

The first general session will begin at 2:00 p.m. on May 21 and comprises seven papers of general interest. Late that afternoon there will be a meeting of the supervising censors, followed in the evening by the annual meeting of the Council.

On the following morning, following four papers on miscellaneous topics, the annual meeting of the

Massachusetts Medical Society will be held, the annual oration to be given by Dr. Frank H. Lahey. The afternoon session begins with five papers of general interest and ends with the Shattuck Lecture, which will be given by Colonel John B. Youmans, M.C., A.U.S., chief, Nutrition Branch, Office of the Surgeon General, and professor of medicine, Vanderbilt University School of Medicine, the title being "Nutrition and the War." The annual dinner of the Society will be held that evening, the president, Dr. Reginald Fitz, will preside, the guest speakers being Dr. Roger I. Lee, president of the American Medical Association, and Dr. Elmer S. Bagnall, past president of the Society.

The program for the morning of the third day lists three papers of general interest and a symposium on bleeding from the gastrointestinal tract. At noon, the various sections will hold luncheon meetings, at each of which a short talk will be given on an appropriate topic. The meeting will conclude with the afternoon session, the program consisting of seven papers on miscellaneous topics.

The scientific and technical exhibits will be larger than ever before. Tremendous advances in the diagnosis and treatment of disease were made during the war years, and many of these are now being made available to the general practitioner for the first time. For this reason all the exhibits, particularly the technical ones, deserve the close attention of those who attend the meeting.

The usual continuous motion-picture program is scheduled for the second and third days.

An interesting schedule has been arranged for the wives of members, including attendance at the Pop Concert at Symphony Hall on the evening of the first day. A golf tournament for members will be held at the Wollaston Golf Club on the afternoon of the second day.

The Committee on Arrangements, which is composed of Dr. Roy J. Heffernan, chairman, and Drs. G. Guy Bailey, Jr., Harold G. Giddings, Robert L. Goodale and Sidney C. Wiggan, has set forth a program that should appeal to the returned veteran and to the general practitioner, and it seems likely that all previous records of attendance will be shattered.

showed all these findings in the lungs, but in addition, when the chest plate was removed, a large puff of air came out of the left chest and the left lung was found way over to the right against the spine. She undoubtedly had, as Dr. Greene mentioned, a pneumothorax. We have here then a combination of two conditions—the type of lung that is found in an asthmatic paroxysm and a pneumothorax. I believe that the latter was probably the precipitating cause of death. This is the first case of pneumothorax as a complication of an asthmatic paroxysm that we have had.

DR. RACKEMANN: I should like to ask Dr. Lingley if he would look at the x-ray films again to see if he

can find an emphysematous bleb. Why did the lung rupture?

DR. LINGLEY: There is no visible evidence of a bleb in this film.

DR. CASTLEMAN: The left lung showed two or three emphysematous blebs, but we were unable to find a definite tear. There was a moderate degree of emphysema throughout the lung, and definite hypertrophy of the right ventricle.

MEDICOLEGAL ABSTRACT

Regulation of Practice by Government Unauthorized practice. The defendant was a licensed cosmetologist and operated a "clear-skin" institute. He was charged with practicing medicine without a license in violation of Michigan Comp Laws 1929, Paragraphs 6743 and 6745. A jury found him guilty, and he appealed. The judgment was affirmed. The evidence showed that the complaining witness was suffering from acne and that the defendant, for a fee, undertook to treat her and did treat her by means of applying ointment and extracting blackheads. A physician qualified as an expert on skin diseases testified that papular acne "ordinarily spoken of as pimples," was a disease a physician without special training in dermatology would find difficult to differentiate from secondary syphilis and that it would certainly require a physician to treat it. There was some other evidence that the defendant engaged in the practice of medicine in violation of the statute — *People v Gilbert* 312 Mich 320, Oct. 8, 1945.

This case, however, is particularly interesting because it calls attention to the exceedingly broad provisions of the Michigan statute under which the conviction was obtained. Paragraph 6743 of the Comp Laws of 1929 makes it a misdemeanor to practice medicine without a license. Paragraph 6745 defines the practice of medicine as the actual diagnosing, curing or relieving in any degree, or professing or attempting to diagnose, treat, cure or relieve any human disease, ailment, defect or complaint, whether of physical or mental origin, by attendance or advice or by prescribing or furnishing any drug, medicine, appliance, manipulation or method, or by any therapeutic agent whatsoever. One has no need to be a lawyer to see how sweeping would be a literal construction of the provision making it criminal "to relieve by advice any human complaint of mental origin."

Although a chiropractor is not under Michigan law a physician or surgeon (*Erdman v Great Northern Life Ins Co*, 253 Mich 579), he is licensed under other provisions of the statute so that he can practice medicine — *Locke v Ionia Circuit Judge*, 184 Mich 535 and *People v Lewis*, 233 Mich 240. Similarly pharmacists are separately licensed. Although nurses are not specially licensed in Michigan they would seem to be within the principle that treatment given under supervision and direction of a doctor is not in violation of the statute — *In re Carpenter's Estate*, 196 Mich 561. The practice of midwifery alone, not accompanied by any other practice of medicine and surgery, is also excluded by interpretation.

Other limitations are not so clear. In *Locke v Ionia Circuit Judge*, 184 Mich 525, at 539, the court said

This sweeping effort at denunciation, with all provisions otherwise taken into account would render criminal numerous gratuitous and humane acts of relief and kindness to the suffering common amongst mankind in all ages and places. The police power of the state, though comprehensive, is scarcely adequate to compass the possibilities of such a definition, and it is difficult to discern in the title of the act any warning of a purpose to make such definition a part of the law of this commonwealth.

In *People v Watson*, 196 Mich 34, the court said that some acts covered by the language of the statute might be innocently done. The assumption that things so done would not be in violation of the statute is clear. The meaning of things "innocently done" is not so clear. Certainly no criminal intent or *mens rea* is required to constitute the crime penalized by the statute. The court did, however, refer with approbation to the exception of "gratuitous and humane acts" made above. The notion that the statute would be limited to those who engage in the practice of medicine for gain and as a vocation is further strengthened in *People v Eckelyn*, 217 Mich 341. The nature of the acts done, however, would seem to be much more relevant than the question of whether they were done for charity or for pay. Thus, performing an appendectomy is practicing medicine even when done for charity, while consoling a widow could hardly be so considered even if were done in pursuit of a vocation.

Despite the broad language of the act there are extremely few cases under it, limitation in its meaning apparently depending primarily on the good sense of the prosecuting authorities.

MISCELLANY

PASSANO FOUNDATION AWARD

Selection of Dr Ernest W Goodpasture, professor of pathology and dean of the School of Medicine of Vanderbilt University, Nashville, Tennessee, as the 1946 recipient of the Passano Foundation Award is announced by the Board of Directors of the Foundation. Presentation of the \$5000 cash award will be made at an appropriate ceremony in Osler Hall of the Medical and Chirurgical Faculty of Maryland, in Baltimore, on the night of May 15. The Foundation, which was established in 1944 by the Williams and Wilkins Company, of Baltimore, proposes to aid in any way possible the advancement of medical research, especially research that bears promise of clinical application. For the encouragement of such research the Foundation has established the award as one of its activities. Following the presentation of the award by Mr Edward B Passano, chairman of the Board of Directors of the Williams and Wilkins Company, Dr Goodpasture will deliver an address entitled, "Research and Medical Practice." Dr Goodpasture receives the award for his original development of the method for propagation of viruses in pure culture by inoculation of chick embryos and for his outstanding contributions to advancement of knowledge of the cell-parasite relation in bacterial and viral infections.

DR O'HARA APPOINTED DEAN AT TUFTS

Dr Dwight O'Hara, of Waltham, who is president-elect of the Massachusetts Medical Society, has recently been appointed dean of Tufts College Medical School. Dr O'Hara has been professor of preventive medicine at the school for a number of years and has been acting dean for the past four years, in the absence of Dr A Warren Stearns, who served as a captain in the Medical Corps of the United States Navy. Dr Stearns has been made head of the newly created Department of Applied Sociology at the Tufts School of Liberal Arts.

THE INADEQUACIES OF MEDICAL CARE

V HOW THEY CAN BE CORRECTED

THIS final editorial summarizes the suggestions made in the previous editorials concerning the correction of existing inadequacies of medical care. These comments will not be listed according to particular aspects but according to the agency that is responsible for their accomplishment.

The Government should promote an economy that guarantees good wages and a high standard of living, including adequate housing and transportation facilities. It should establish grants-in-aid to states in which there is demonstrated need for facilities concerned with the health of the people, incidentally, this could best be accomplished by the creation of a national department of health, headed by a secretary of Cabinet rank. Through an extension of the Social Security Act it should provide compensation for loss of wages due to sickness. Finally, it should organize, supervise and support a scheme for the continuance of co-ordinated medical research.

State governments should take the necessary steps, statutory or otherwise, to assure the licensing of well trained physicians, to eliminate improper medical practice by cultists, to improve hospital standards, to guarantee the necessary funds for the care of the indigent and to encourage an increase in nursing personnel through the licensing of attendant nurses. They should construct and equip hospitals and health centers in areas of demonstrated need and, if necessary, should employ or subsidize physicians in these institutions, all with the assistance of federal grants-in-aid. They should educate the public concerning matters of diet, accepted methods of preventive medicine and available facilities for medical care.

Medical schools should pay more attention to the need for training physicians who qualify as general practitioners rather than as specialists.

Both national and state medical societies should sponsor comprehensive programs for postgraduate medical education. State medical societies should assist state departments of health in educating the public regarding preventive medicine and available medical facilities, chiefly through the medium of

district and local health councils, and should promote plans for the assistance of those physicians who have had a substandard education.

Physicians should keep themselves professionally "fit" and should limit their practice to cases for which they are qualified to care. In certain instances, they should consider the advantages offered by group practice.

The number of hospital beds must be increased, and as a temporary expedient, hospitals should make full use of existing facilities. If necessary, they should improve equipment and personnel to meet accepted minimum standards. They should seriously consider the advisability of establishing affiliated convalescent homes.

All these things would do much to improve the health of the people, *but* they would not appreciably lower the cost of medical care. In other words, people must still insure against the expense of catastrophic illness, and the mere fact that they do has little to do with assuring good medical care. Indeed, a healthier Nation can only result from the combined efforts of a variety of agencies — governmental and otherwise. For this reason there seems to be little excuse for maintaining that a nation-wide system of compulsory health insurance is the *only* solution to the problem. It is true that such a scheme would solve one of the difficulties, — equalization of the costs of medical care, — but at the same time it would seriously handicap, if not abolish, many existing enterprises that are gradually accomplishing the very things that contribute to the improvement of medical care. Such enterprises, particularly voluntary schemes for prepayment medical-care insurance, should be encouraged and promoted by the medical profession and by the public, and they should be supported by states, cities and towns, if necessary through federal grants-in-aid.

MASSACHUSETTS MEDICAL SOCIETY

DEATH

FESSENDEN — Charles H. Fessenden, M.D., of Newton, died April 19. He was in his eighty-third year.

Dr. Fessenden received his degree from Boston University School of Medicine in 1886. Until his retirement ten years ago, he had been for many years an x-ray specialist at Newton Hospital.

His son, two grandchildren and two great grandchildren survive.

OFFICERS OF THE MASSACHUSETTS MEDICAL SOCIETY, 1945—1946

DR. DWIGHT O'HARA, *President-Elect**Bachrach*

- 2.25 *Results of Bilateral Suprardiaphragmatic Splanchnostomy for Arterial Hypertension* DR. MAX A PEET, Ann Arbor, Michigan Professor of surgery, University of Michigan, chief, Neurosurgical Unit, University Hospital
- 2.50 *Delayed Chemical Pneumonitis* DR. HARRIET L HARDY, Boston Physician to Division of Occupational Hygiene, Department of Labor and Industries, Commonwealth of Massachusetts, assistant in medicine, Massachusetts General Hospital
- 3.15 *Diabetes in Massachusetts* DR. ELLIOTT P JOSLIN, Boston Medical director, George F Baker Clinic, New England Deaconess Hospital
- 3.40 *Surgical Problems in the Management of a Diabetic Patient* DR. LELAND S MCKITTRICK, Boston Surgeon-in-chief, Palmer Memorial Hospital, visiting surgeon, Massachusetts General Hospital
- 4.00 *The Shattuck Lecture Nutrition and the War* COLONEL JOHN B YOUNG, MC, AUS Chief, Nutrition Branch, Office of the Surgeon General, Washington, D C, professor of medicine, Vanderbilt University School of Medicine
- 1:00-3:00 *Annual Golf Tournament* (WOLLASTON GOLF CLUB, QUINCY, MASSACHUSETTS) — DR. JOSEPH H CAREY, Chairman

WEDNESDAY EVENING, MAY 22

- 7:00 *Annual Dinner of the Massachusetts Medical Society* (GEORGIAN ROOM)

Presiding

DR. REGINALD FITZ, president, Massachusetts Medical Society

Guest Speakers

DR. ROGER I LEE, president, American Medical Association

DR. ELMER S BAGYALL, past-president, Massachusetts Medical Society

Ladies are cordially invited to attend the dinner

Tickets for the dinner must be procured in advance of the meeting

THURSDAY MORNING, MAY 23

Fourth General Session

GEORGIAN ROOM

DR. ARCHIBALD MCK FRASER, *Chairman*

DR. ARTHUR J GORMAN, *Co-chairman*

- 9:00 *The Hospital as a Center of Education* DR. WALTER G PHIPPS, Salem Chief of the Surgical Service, Salem Hospital

Discussers DR. H QUIMBY GALLUPE, Waltham and DR. CHARLES F WILINSKY, Boston

- 9.25 *The Initial Care of the Injured* DR. GORDON M MORRISON, Boston Chairman, Massachusetts Fracture Committee, American College of Surgeons

Symposium Bleeding from the Gastrointestinal Tract

- 9:50 *Gastrointestinal Bleeding Diagnostic and therapeutic considerations* DR. CHESTER M JONES, Boston Physician, Massachusetts General Hospital, clinical professor of medicine, Harvard Medical School
- 10:15 *Surgical Aspects of Hemorrhage in Peptic Ulcer* DR. GEORGE HEUER, New York City Professor of surgery, Cornell University Medical College, surgeon-in-chief, New York Hospital
- 10:40 *The Position of the Roentgenologist in Handling Patients Bleeding from the Gastrointestinal Tract* DR. RICHARD SCHATZKI, Boston Radiologist, Massachusetts General Hospital
- 11:15 *Question-and-Answer Period*
- 11:30 *Comparative Uses of Pentothal Sodium in Military and Civilian Practice* DR. RALPH M TOVELL, Hartford, Connecticut Director of anesthesia, Hartford Hospital DR. CHARLES BARBOUR, member of staff, Hartford Hospital

THURSDAY NOON, MAY 23

Section Meetings and Luncheons

12:00 M — 2:00 P M

Tickets for all luncheons must be purchased in advance

Section of Medicine

PARLOR B, HOTEL STATLER

DR. ALBERT A HONOR, Boston *Chairman*

DR. DANIEL J ELLISON, Lowell, *Vice-chairman*

PROGRAM OF THE ONE HUNDRED AND SIXTY-FIFTH ANNIVERSARY OF THE MASSACHUSETTS MEDICAL SOCIETY

Tuesday, Wednesday and Thursday, May 21, 22 and 23, Hotel Statler, Boston

The Registration Desk will be located on the Mezzanine Floor, and all who attend the meeting are requested to register

Owing to the lack of personnel and food supplies, the Hotel Statler must be informed concerning the number of members who will attend the various luncheons and dinners. Attendance is not limited, but tickets *must* be obtained in advance.

Members of the Society who are not councilors may obtain tickets for the Pop Concert on Tuesday evening by purchasing them (\$1.50 each) from Society Headquarters, 8 Fenway, Boston 15, on or before May 15. Their wives and friends are cordially invited to attend.

TUESDAY AFTERNOON, MAY 21

First General Session

GEORGIAN ROOM

DR. RALPH R. STRATTON, *Chairman*

DR. CARL BEARSE, *Co-chairman*

- 2:00 *Foreign Bodies in the Respiratory Tract* DR. JOHN R. RICHARDSON, Boston Assistant surgeon, Massachusetts General Hospital and Massachusetts Eye and Ear Infirmary, bronchoscopist, Massachusetts Eye and Ear Infirmary
- 2:25 *The Problem of Venous Thrombosis and Pulmonary Embolism* DR. JOHN HOMANS, Boston Clinical professor of surgery (emeritus), Harvard Medical School
- 2:50 *Anal Pruritus* DR. NEIL W. SWINTON, Waban Surgeon, Lahey Clinic and New England Deaconess and New England Baptist hospitals
- 3:15 *Anoxia Neonatorum* DR. CHARLES L. SULLIVAN, Chestnut Hill Assistant obstetrician, Massachusetts General and Saint Elizabeth's hospitals
- 3:40 *Progress — Penicillin Inhalation Therapy* DR. MAURICE S. SEGAL, Boston Assistant professor of medicine, Tufts College Medical School, junior visiting physician, Boston City and Beth Israel hospitals
- 4:05 *Functional Gastrointestinal Disorders: Lessons learned from military medicine* DR. JAMES A. HALSTED, Dedham Assistant physician, Massachusetts General Hospital
- 4:30 *Tuberculosis Case Findings* DR. JOHN A. FOLEY, Boston Director 5th and 6th Medical Services, Boston City Hospital, chief of staff, Boston Sanatorium, clinical professor of medicine, Boston University School of Medicine. DR. JOHN B. ANDOSCA, Boston Instructor in medicine, Boston University School of Medicine

- 5:00 Supervising Censors' Meeting (PARLOR D)
- 6:00 Cotting Supper for Councilors (PARLORS A AND B)

TUESDAY EVENING, MAY 21

- 7:00 Annual Meeting of the Council (GEORGIAN ROOM)
- 8:30 Pop Concert (SYMPHONY HALL)

WEDNESDAY MORNING, MAY 22

Second General Session

GEORGIAN ROOM

DR. W. JASON MIXTER, *Chairman*

DR. CHARLES J. E. KICKHAM, *Co-chairman*

- 9:00 *Some Observations on the Recent Food Rationing Program* DR. JOSEPH GARLAND, Boston Physician to the Children's Medical Department, Massachusetts General Hospital
- 9:25 *The Diagnosis and Treatment of Infective Hepatitis* DR. WILLIAM C. MOLONEY, Boston Assistant professor of clinical medicine, Tufts College Medical School, visiting physician, Carney and St. Elizabeth's hospitals
- 9:50 *Tropical Diseases in World War II Returnees* CAPTAIN JAMES J. SAPERO (MC), U.S.N., Washington, D.C.
- 10:15 *Streptomycin* DR. CHESTER S. KEEFER, Boston Director, Evans Memorial, Massachusetts Memorial Hospitals, physician-in-chief, Massachusetts Memorial Hospitals
- 11:00 Annual Meeting of the Massachusetts Medical Society (GEORGIAN ROOM)
- Annual Oration (following annual meeting) Gastric Surgery DR. FRANK H. LAHEY, Boston Director, Lahey Clinic, surgeon-in-chief, New England Deaconess and New England Baptist hospitals
- Annual Luncheon (PARLORS A, B AND C) tickets must be procured in advance of the meeting

WEDNESDAY AFTERNOON, MAY 22

Third General Session

GEORGIAN ROOM

DR. ELMER S. BAGNALL, *Chairman*

DR. JOHN FALLON, *Co-chairman*

- 2:00 *Medical Aspects of Hypertension* DR. NORMAN A. WELCH, Boston Clinical professor of medicine, Tufts College Medical School, physician-in-chief, Carney Hospital

2.25 *Results of Bilateral Supradiaphragmatic Splanchnicectomy for Arterial Hypertension* DR MAX A PEET, Ann Arbor, Michigan Professor of surgery, University of Michigan, chief, Neurosurgical Unit, University Hospital

2.50 *Delayed Chemical Pneumonitis* DR HARRIET L HARDY, Boston Physician to Division of Occupational Hygiene, Department of Labor and Industries, Commonwealth of Massachusetts, assistant in medicine, Massachusetts General Hospital

CORRESPONDENCE

MILITARY MEDICINE

To the Editor The writer of the editorial "Merger and Medical Service," which appeared in the March 28 issue of the *Journal*, has expressed some views which deserve further comment. It seems to me that, in advocating a merger of the medical services of all the armed forces, he has gone unnecessarily far out of his way to disparage military medicine as practiced during the recent international disagreement.

One's opinions on almost any subject are derived either from what he himself has experienced or from what he has read or heard of the experiences of others. If the gentleman who wrote this editorial served personally with the Medical Corps of the Army or Navy he has, of course, every right to express his views, however dim they may be, but if this is actually the case, I suggest that his experience differed considerably from that of the majority of medical officers. If his expressed opinions are based on hearsay, as he seems to imply, I submit that possibly he has listened too attentively to a vocal minority, many of whom have purely personal reasons for their dissatisfaction with military medicine.

Although I am not qualified to speak of medicine in the Navy or of Army medicine in the Asiatic-Pacific or Mediterranean theaters, forty-four months' experience as an Army medical officer in this country, England, France and Germany has brought me to the following conclusions, with which I believe that the vast majority of my former colleagues would agree.

Army medicine is in so many respects superior to civilian medicine that there is no legitimate basis for comparison. This is a sweeping generalization, but there are so many specific examples by which it can be substantiated that I hardly know where to begin. I should ask your editorialist to consider the incidence of typhus in the American army in the ETO, I should ask him what he thinks of the military policy of universal compulsory chest x-ray films on all personnel, I should ask him to cite a single civilian community where expert, free medical care, hospitalization and laboratory facilities are constantly available to anyone at any time, regardless of his social or economic status. Finally, I should ask this: If civilian medicine is so superior, why all the current agitation, from almost every quarter, to remodel it completely?

One frequently hears the statement, "Army medicine was fine, but only because so many civilian doctors joined the Army." The absurdity of this viewpoint becomes apparent when one considers that in time of war no department of the Army would be of much value if it were not for civilian soldiers. No one will maintain that Army medicine was perfect, we all saw situations that could have been improved (and usually were, in time), conditions requiring correction (they usually got it) and procedures that were carried out inefficiently (especially by inexperienced personnel, who later learned Army techniques). In my own personal experience, I never saw a "snafu" of any magnitude that was not the direct or indirect result of some former civilian's attempt to do things in his own—and often highly original—fashion, rather than in the time-tested and experience-proved Army way.

I do not understand exactly what your writer means when he speaks of medical officers being "treated as enlisted men." The statement is too vague for comment. When he states that they were "ordered to do menial duties," I should again like more details. I, myself, never saw this happen. I know many a former major or colonel who is not now above helping his wife with the after-supper dishes, none ever washed a plate in the Army. I wonder what the "menial duties" were, and who gave the orders.

If the writer of your editorial would accompany me to any local civilian hospital he cares to designate, I shall undertake to point out to him defects in cleanliness, sanitation and administration that would not be tolerated in an Army installation. He will probably see gum-chewing ward attendants, dirty food handlers, smoking in kitchens, orderlies in need of shaves or haircuts, dusty floors, unnecessary noise, grime under the radiators—but why go on?

Finally, one should consider the care of the patient. In the last analysis, this will always depend for its quality

on the character and qualifications of the doctors and nurses in attendance, and, to a lesser extent, on the amount and nature of the material, human as well as inanimate, that is available to assist them. Where but in the Army (or Navy) are to be found hospitals that combine all the following features: every nurse a graduate, every ward officer having completed at least one internship, and many, residencies, an almost unlimited supply of drugs, instruments, hospital furnishings and professional equipment of every type, a competent visiting staff actually in residence, expert consultants in every branch of medicine and surgery, always available, well trained, well disciplined ward personnel, laboratory, x-ray and other diagnostic facilities constantly at hand, with no restrictions on their legitimate use, the whole, at no cost to the patient, and in fact with economic considerations of any kind never a limiting factor.

Many of us who served with the forces deplore the currently fashionable tendency to indulge in the indoor sport of "knocking the Army." We resent it for a variety of reasons, but chiefly perhaps for these three:

We were there and know from our own observations that the over-all picture was superlatively good.

We do not understand how any civilian, however talented or however "vocal," can possibly be in a position to judge the quality of military medical care.

We observe, often to our own embarrassment, that the most virulent criticism almost invariably emanates from those who have purely personal grievances, whether real or imaginary, against the military system, one, perhaps, failed to get promoted, another was relieved of his command, a third is upset because "someone else got the Legion of Merit." This translation of personal and usually deserved misfortune into a blanket condemnation of the Army as a whole is as subversive and as unconstructive as it is ill had taste.

WINTHROP WETHERBEE, JR.

24 School Street
Boston

* * *

The editorial in question does not unqualifiedly condemn military medicine. It does, however, imply that mistakes were made and that much might be accomplished toward future improvement if these faults were acknowledged and attempts were made toward their correction. Unfortunately, the experiences of many of the medical officers, particularly those assigned to small medical units, were not so satisfying as those of Dr. Wetherbee and his associates.

It is extremely difficult and hazardous to compare military and civilian medical care, since the recipients of the former are controlled by a rigid system of discipline. On the other hand, it must be acknowledged that the majority of advances, particularly in peacetime, originate in the large teaching units, and the editorial suggests that one of the aims of a merged medical department might well be a closer affiliation with such units than has existed in the past.—En

REPORT OF MEETING

MASSACHUSETTS CENTRAL HEALTH COUNCIL

The annual meeting of the Massachusetts Central Health Council was held on April 9, 1946. At the business meeting, after reports for the year by the president and the secretary-treasurer, the following officers were elected for the ensuing year: president Dr. George C. Shattuck, vice-president Dr. Channing Frothingham, and secretary-treasurer Mr. Arthur J. Strawson.

The business meeting was followed by a discussion entitled "Symposium on Group Practice." The principal speaker was Dr. Kingsley Roberts, director of Medical Administration Service, Incorporated, New York City.

Dr. Roberts approached the subject from the angle of better distribution of good medical care. He believed that, however financed, medical care should be organized on a prepayment basis, that the unit for care should be the family and not the individual, that the plan should include care in the home as well as in the hospital, and that the use of preven-

*The opinions expressed are those of the speakers. The Massachusetts Central Health Council has taken no position for or against group practice.

nive methods should be an essential part of the plan. To these ends, physicians should know more about socioeconomic matters and about how to persuade patients to take advantage of the periodic physical examination and of other means of conserving health. He added that some units offering group practice are well organized and that others are not. Certain of them offer only diagnostic, consultative or specialized services. Others offer service of a general character. For broad medical coverage, co-ordination of the work of the staff by a person who understands preventive as well as curative medicine is essential. Research should also be a function provided for in the budget.

The development of group practice, in the opinion of Dr Roberts, is necessary to keep down cost, to promote the efficient distribution of medical care and to encourage the systematic application of preventive methods.

For the future, Dr Roberts envisioned health centers in small communities, to be served by groups of physicians. A number of such health centers should be affiliated with a teaching and hospital unit in the nearest large city, and a flow of personnel back and forth between the teaching unit and the health centers should be provided for. Such a plan would not only improve medical service in small communities but it would also provide the participating physicians in such communities with an adequate income and educational advantages.

Dr Roberts then contrasted several types of group practice that are now in operation and said that many medical veterans have been impressed with the advantages of group practice as it exists in the Army and have been asking advice about how to form or to join a group for practice in civil life. The formal discussion was opened by Dr Elmer S. Bagnall of Groveland. Dr Bagnall deplored the fact that discussions of possible changes in medical organization too often are characterized by conservatism. He believed that discussions aimed at expanding the areas of agreement should continue to be held and that this approach would prove profitable. Although not a member of a medical group, Dr Bagnall said that the problems of organizing group medicine are worthy of study. Because people in a democracy resent regimentation and insist on the right to make mistakes, he thought that change should be gradual and by evolution. As a means of further study of medical problems on a community basis, Dr Bagnall added that the formation of local health councils should be further stimulated, and he pointed out that the Massachusetts Medical Society has been discussing a two-way system of arranging for hospital care through central hospitals and subsidiary hospitals. The importance of the general practitioner as the co-ordinating link between the patient and the various specialists was stressed.

Dr Fallon, of Worcester, who has been practicing in a group for many years, emphasized the ease of consultation within the group and the fact that diverse opinions can be expressed with the utmost freedom. Usually, the patient gets the benefit of at least two viewpoints. Laboratory and x-ray examinations are facilitated. When the cost of x-ray examination exceeds a specified figure, the group bears the additional expense. The members of the group, although specially qualified in certain fields, perform general work as well, and the internist gets a more equitable remuneration than is usual when surgery is required.

He added that there are many obstacles to success in group practice. Consequently, many groups have survived for only a few years. Dr Fallon said that he did not wish to see group medicine replace the family doctor, who alone can have intimate knowledge of the patient's background.

Dr Parkhurst, of Beverly, a member of a medical group, expressed interest in the plans outlined by Dr Roberts but thought that it would be a long time before such a plan could be put into successful operation. He and other members of his group see patients not only in the office but also in the home. The patient chooses his physician within the group, but the group does not attempt to replace the general practitioner. Since a group is only as good as the men behind it, it should be built on the basis of ability to give good service rather than be formed from the physicians who happen to reside in the same locality. In certain instances it may be necessary to bring in outsiders having special qualifications. He added that a well organized group can not only provide improved services to a community but it may also become the nucleus of an efficient hospital staff.

Dr Lendon Snedeker, of Boston, who at present is engaged in a fact-finding survey of health services for children in

Massachusetts sponsored by the American Society of Pediatrics, said that Dr Roberts's tentative plan is not unlike a scheme that is now in operation in Sweden, with private practice as an overlay. "Why, indeed," he said, "cannot a general practitioner who is the family counselor be the key man in a group?"

In closing, Dr Roberts pointed out that his general plan can be and should be adapted to local needs and that he too was convinced of the need for the general practitioner.

BOOK REVIEWS

Neuro-Ophthalmology, By Donald J. Lyle, M.D. 4th cloth, 395 pp. with 234 illustrations. Springfield, Illinois: Charles C. Thomas, 1945. \$10.50.

This book, the first American text to cover overlapping territory in the fields of neurology and ophthalmology, should prove a useful reference summary for practitioners and teachers of neurology and ophthalmology. Material for the text has been derived from 130 case histories, in all but 4 of which the clinical diagnoses were verified anatomically. Seventy-one pages are given to over seventeen hundred references, alphabetically arranged. There are 234 black-and-white figures with 529 separate illustrations, diagrams or photographs.

Ophthalmologists particularly should be grateful to the author for portraying vividly by pen and picture the related neurologic and ophthalmologic aspects of intracranial lesions and for correlating the same by collateral anatomical diagrams and photomicrographs, x-ray photographs, visual fields and fundus photographs. One of the outstanding virtues of this work is that it brings to the ophthalmologist a neurologic point of view and a better understanding of visuomotor and visuosensory pathology.

Although the reviewer has only admiration for this important work, and faith that revision for the second edition will iron out the few rough spots, he wonders how the publisher could fail to include much of the preface and the first ten pages of Chapter I, whether the author would not consider it helpful to clarify the signs in supranuclear, nuclear, infranuclear and internuclear lesions affecting the third, fourth and sixth cranial nerves, and whether half the photographs of fundi should be replaced by more informative diagrams or photomicrographs of significant intracranial lesions.

Clinical Roentgenology of the Digestive Tract. By Maurice Feldman, M.D. Second edition. 8th, cloth, 769 pp., with 551 illustrations. Baltimore: The Williams and Wilkins Company, 1945. \$7.00.

This book is largely a review of the older literature, giving major points in roentgenologic diagnosis and stressing their clinical application. For the student of roentgenology or of gastroenterology, too many varieties of lesions, with rather questionable proof, are stressed. For the practitioner of either roentgenology or gastroenterology, however, the book should be an excellent reference source, so long as common sense is used in interpreting the extremely uncommon or doubtful types of lesions.

An excellent index and bibliography are included. The latter is divided, being appended at the end of each section, which makes it of particular value because of its ready accessibility.

Peripheral Nerve Injuries: Principles of diagnosis. By Captain Webb Haymaker, M.C., A.U.S., and Major Barnes Woodhall, M.C., A.U.S. 8th, cloth, 227 pp., with 225 illustrations. Philadelphia: W. B. Saunders Company, 1945. \$4.50.

This book covers a field already well cultivated. The particular value of this publication lies, however, in the expert condensation and the unusual illustrations. The text is accurate and dependable, but the student or physician will gain most from a study of the photographs and drawings that accompany it. No previous publication on this subject is more clearly illustrated. Each maneuver of testing motion is not only described, but all phases of it are shown in the pen sketches. The book should appeal to a wide audience,

particularly medical students and physicians who practice neurology and neurosurgery. Printed on excellent paper, with clear type and a good binding, this book deserves the highest recommendation. It was widely distributed by the United States Army.

The Falling Sickness. A history of epilepsy from the Greeks to the beginnings of modern neurology. By Owsei Temkin, M.D. 4th, cloth, 380 pp., with 7 illustrations. Baltimore: Johns Hopkins Press, 1945. \$4.00.

Dr. Temkin, who is an associate professor in the Department of History of Medicine at Johns Hopkins University, writes on the history of epilepsy from the time of the earliest reference by the ancient Greeks to 1880, when the effect of the work of Hughlings Jackson and Charcot became incorporated into medical thought. Naturally, much of the material, particularly that dealing with the earlier periods, is extracted from works dealing with speculations found in the opinions of laymen, philosophers and theologians, as well as those of physicians. The disease was closely associated with magic, lunacy, theology and the literature surrounding such vague subjects as the supernatural and the occult. It was not until the beginning of the nineteenth century that epileptic patients began to be hospitalized and carefully observed. Charcot separated out the epileptic manifestations due to hysteria, and Jackson, the symptoms resulting from a focal lesion in the brain.

Dr. Temkin has covered the whole story in a skillful manner. References are given to every statement of fact. His style is meticulous, and the chapters are supplemented by an extensive bibliography and an excellent index. The book is a credit to American medicine in the historical field and should be of use to all historians and those physicians who have to deal with convulsive disorders.

The Modern Medical World. Portraits and biographical sketches of distinguished men in medicine. By Solomon R. Kagan, M.D. 8th, cloth, 223 pp., illustrated. Boston: Medico-Historical Press, 1945. \$6.00.

In this volume the author presents a series of admirable biographical sketches and portraits of three hundred and twenty medical men distinguished for their notable contributions to science from the beginning of the nineteenth century. A large proportion of the portraits are reproduced for the first time. The names are arranged not alphabetically but chronologically under groups of men working in identical fields. In this collection and publication Dr. Kagan makes a valuable contribution to the record of modern medical history.

Microbial Antagonisms and Antibiotic Substances. By Selman A. Waksman, M.S. and Ph.D. 8th, cloth, 350 pp., with frontispiece. New York: The Commonwealth Fund, 1945. \$3.75.

The chasms separating many of the fields of abstract and applied science are often as wide as that between science in general and the layman's understanding thereof. This is a book bridging one such void between the field of soil and water microbiology, where microbial antagonism is an old story, and practical medical science, where antagonism was, until recently, a forgotten one.

The first two chapters discuss soil and water micro-organisms and their interrelations. Taken as a group, these forms of life make up the oldest of all living associations. It soon appears that they also have their parasitic parvenues. In the third chapter the field narrows to a consideration of these. The medical reader may be somewhat startled to find that the author apparently favors classifying one of medicine's venerable D.A.R.'s, the leprosy bacillus, as a "facultatively parasitic soil organism." The field still further narrows, however, to include only those parasites which have developed mass-murder methods of a high order against their fellow microbes. The fourth chapter, replete with research suggestions and possibilities, outlines methods of finding and isolating these antagonistic organisms and of identifying and assaying their products.

The next five chapters cover the known antagonists and the antibiotic agents of five broad groups of micro-organisms — bacteria, actinomycetes, higher fungi, protozoa and viruses. The tenth chapter lists the thirty-odd antibiotic agents of note in the five broad groups and outlines what is known of their chemical composition. The eleventh discusses antibiotic action and distinguishes it from antiseptic action. The remaining chapters take up present applications and future possibilities.

The applied scientist usually likes his data in handy-reference form and may regret that each antibiotic substance is treated in so many places in the book. Many such readers could benefit from an example of thorough, if apparently digressive, treatment. Good balance is maintained in the handling of the various substances — none, not even the author's favorite, receiving undue consideration at the expense of the others.

The book provides the interested beginner with the technique and basic background needed for a start. At the very least it should give the conventional bacteriologist with his mania for pure-culture study something more exciting to look for than the discard-bucket when he finds bacterial and mold contaminants on his plates. The sixty-page bibliography will keep him from rushing into print with his first discovery.

NOTICES

ANNOUNCEMENTS

Dr. George L. Maltby announces the opening of an office at 29 Deering Street, Portland, Maine, for the practice of neurological surgery.

Dr. Philip S. Marcus, having returned from military service, announces the reopening of his office for the practice of anesthesiology at 270 Commonwealth Avenue, Boston.

Dr. H. Herman Shuman announces his return from military service and resumption of the practice of pediatrics at 34 Maple Street, Springfield.

Dr. Garrett L. Sullivan, having returned from military service, is resuming the practice of ophthalmology at 101 Bay State Road, Boston.

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Ring Sanatorium and Hospital, Arlington, on Thursday, May 16, at 8 p.m. Dr. John G. Trump will speak on the topic, "High-Voltage X-Rays and Cathode Rays for Cancer Therapy."

HEALTH BILLS PENDING IN CONGRESS*

Part One

FRANZ GOLDMANN, M.D.†

NEW HAVEN, CONNECTICUT

THE fight over a national health program is on. An unprecedented number of bills for the improvement and extension of health services is pending in Congress. We may be confused by this flurry of legislative activity and may differ in our opinions about the merits of these bills. But we may be said to be at heart on the side of any program designed to adjust the health services to the rapid progress of medical science and the profound socioeconomic changes that have taken place since the nineteenth century.

Naturally and inevitably, one question is immediately raised. Is there any need for a nation-wide health policy as contrasted to local development of health programs? To answer this question one must define the unmet needs.

PUBLIC-HEALTH SERVICES

There is need for the extension and strengthening of the basic public-health services. Despite creditable achievements in the development of community-wide services designed to prevent illness and promote good health, the goal is far from being reached. Full-time health units are operating in less than two thirds of all counties, and many of these are without adequate staffs and sufficient funds. The annual per capita expenditure for local health work is \$0.61, whereas about \$1.00 would be necessary to meet at least the most urgent requirements, and \$2.00 to \$2.50 to meet them all. But the problem is not only one of allotting more money, its solution also requires a reorganization of administrative structure.

Historically, the responsibility for the administration of local health services has been vested in the city, town, village or township. Many of these units are too small in population or too weak in resources to employ the necessary full-time public-health personnel. After years of study, a committee of the American Public Health Association,¹ headed by Dr. Haven Emerson, has proposed a plan whereby the 3070 counties and their contained cities in the

United States can be served by 1197 units of local health administration. More than two thirds of these units would serve several counties. It is imperative to create service districts rather than to continue the administration of public-health services by small political units.

FACILITIES FOR MEDICAL CARE

There is need for more hospital beds, for better distribution of the various types of hospitals and for improvement of the quality of many facilities for medical care. In response to an ever growing demand, the number of hospital beds in this country has increased from about 35,000 in the early 1870's to 1,729,945 in 1944, or from approximately 1 bed to more than 12 beds per 1000 population, although it must be borne in mind that some 550,000 beds are in federal hospitals restricted to certain groups.

Despite and because of this great progress, we must not rest on our laurels. There are shortcomings that ought to be eliminated. The over-all bed rate falls short of present standards. According to the prevailing opinion, 4.5 beds in general hospitals are necessary for every 1000 persons, but the actual rate is below 4.0. In mental hospitals 5.6 beds would be necessary, but only 4.6 beds are available. In tuberculosis hospitals there is need for 2 beds for every death from this disease, but there are available only 1.3 beds per death from tuberculosis. Obviously, a substantial number of additional beds must be provided to meet the requirements of the time. No illusion should be entertained about the magnitude of this task.

The distribution of the existing hospitals is extremely uneven. At present, the best supplied states have about three times as many hospital beds per 1000 population as do the states with the lowest bed rates, and this inequality is even greater when only the general hospitals are considered. Hospitals are located where money is abundant and where there is enough wealth to build them and enough purchasing power to pay for their services. The wealthier states comprise about one quarter of those in the Union. The poorer parts of the country, the

*This is the first of a series of four lectures on medical sociology given at the Harvard Medical School during February and March 1946. They were sponsored by the Department of Preventive Medicine and were primarily intended for third year students.

†Associate clinical professor of public health, Yale University School of Medicine.

very regions undersupplied with hospital beds, have more need for modern treatment service

Certain types of facilities are conspicuous by their rarity. This applies primarily to chronic-disease hospitals and convalescent hospitals, which are necessary for the proper and humane care of the sick as well as for the effective and economical operation of general and special hospitals.

To place emphasis on the number rather than the quality of medical-care facilities would be to ignore a fundamental of hospital policy. The hospital at its best is a superb institution. Many hospitals meet the highest standards, but many others need to be improved, and hundreds of institutions in actual operation are hospitals in name but primitive infirmaries in fact. At present, approximately two thirds of all hospital beds are in hospitals approved by the American College of Surgeons as meeting the standards considered fundamental to good hospital care, and most of them are in the large cities. It is noteworthy that the American College of Surgeons excludes hospitals with less than 25 beds from inspection and approval. According to a special survey made in 1939, nearly one third of all registered and nonregistered facilities for medical care and more than one third of such general and related hospitals had fewer than 25 beds. In 1944, it was found that nearly one fifth of the hospitals registered by the American Medical Association had less than 25 beds. The excuse for the existence of such small facilities is that many of these hospitals offer the *only* inpatient service in small communities. All the facts point to the necessity of reorientation of hospital policy to assure high standards of care throughout the country.

The shortcomings mentioned have discouraged highly skilled physicians from settling in small communities and have induced those practicing in small communities to move to large cities at the earliest possible moment. They have deprived many a country doctor of easy access to a hospital and of the opportunity for intellectual growth and technical assistance.

Since the increase and expansion of hospitals have taken place without over-all planning, governmental and nongovernmental activities in the hospital field are unco-ordinated. They duplicate each other in some communities and are entirely lacking in others. What is needed is a nation-wide hospital policy devised, accepted and carried out by all groups concerned, and concerted action rather than isolated effort.

District health centers, although they are essential to successful public-health work, have just begun to develop. At present they are intended to attain a functional and administrative co-ordination of all local health activities by housing under one roof a variety of clinics and also certain bureaus for the administration of health work within districts. In connection with the formulation of plans for an in-

tegrated hospital system, the potential value of public-health centers to broad health programs has been the subject of much debate. It might be wise to develop the old-type district health centers into centers of both preventive health activities and medical care for the whole community by making them the headquarters of physicians and related groups in private practice as well as of personnel employed by public and private agencies.

DISTRIBUTION OF PHYSICIANS

There is need for better distribution of competent physicians and members of allied professions. The large majority of the physicians in actual practice are graduates of approved schools, but many of the older physicians have had little opportunity to do more than occasional post-graduate work. Early in 1942, about every fifth physician reported himself as a specialist, but only about 18,000 names were listed in the *Directory of Medical Specialists*.

There is a good deal of disagreement concerning what constitutes a satisfactory ratio of physicians to population. Before the war, there was one doctor in active practice for every 935 persons, and this ratio was unsurpassed by any other country. How many physicians will be needed in the future is problematical. The only experience gained relates to organized programs operating on the basis of full-time group practice. Some of these plans, rendering complete service, need one physician for 1000 persons and others one for every 1200. What is not known is the ratio of physicians to population under a broad health program operating on the basis of the individual practice of medicine. In estimating future demand, allowance must be made for full-time service by physicians in public-health work, for the administration of hospitals and clinics and medical-care programs and for special services, such as those of the Veterans Administration.

The distribution of physicians leaves much to be desired. At present, they are concentrated in densely populated areas, large urban centers and relatively rich sections of the country; they are rare, if not lacking, in thinly settled areas, small communities and relatively poor sections. As might be expected, the location of doctors in the past was primarily influenced by the purchasing power of the people in a given community and to some extent by the availability of good hospitals and social and educational advantages. Significantly, the largest number of physicians per unit of population was found in the sections of the country with the largest dollar amount of retail sales per capita. Equally significant is the fact that the accredited specialists, with negligible exceptions, are practicing in large communities with good hospitals.

ORGANIZATION OF PROFESSIONAL SERVICES

There is need for organization of professional services according to the requirements of the time.

With the rapid advance of scientific medicine, the sum total of knowledge and skill has become so great that it cannot be mastered by any single person. The family doctor loses his patients, since people expect more than before from the physician and tend to consult a specialist without first seeing the general practitioner. Inevitably a growing number of young physicians, for one reason or another, are anxious to specialize in one of the many narrowly bounded specialties and refuse opportunities to gain experience in general practice. All too often the patient is regarded as a mere aggregation of parts, seen only through an optical instrument, and is referred from one specialist to another without receiving the services of a physician. The following story written by a British physician,² speaks for itself.

The need for the general physician is illustrated in this true story of six specialists and no doctor. There was a man with inframammary pain who betook himself to a cardiologist, who suspected a spinal-cord lesion and sent him to a neurologist, who diagnosed spinal osteoarthritis and sent him to a radiologist whose x-rays revealed nothing. Being still in pain he went a little later to a chest specialist who discovered nothing but suspected a psychoneurosis and sent him to a psychiatrist who refused to get to work until the man had been to a clinical pathologist who reported that all blood examinations were normal. The patient returned to the psychiatrist and was still in conference with him when last heard of.

One is therefore justified in asking whether the wheels of history are to be turned back and specialization is to be curbed, or whether the family doctor shall be strengthened by being made the link between patient and specialist. The answer is clear. Effort must be concentrated on the smooth co-operation of general practitioners and specialists, so that the general practitioner can readily be the family doctor, the specialist can complement him as he ought to, and the patient can receive the optimum in quality, efficiency and economy of service. The wide recognition of the need for a new approach to the organization of professional services explains the current interest in the development of group practice of medicine.

It is high time to proceed to sound organization of more group-practice units of different types in large cities and smaller communities, so as to gain experience about the best method of organization and the potentialities and limitations of this form of medical practice.

EXTENT OF MEDICAL CARE

There is need for more and better treatment of disease and defects. Innumerable studies on this subject have appeared. A digest of statistical data fills a volume of more than two hundred pages.³ The findings differ in detail but are alike in regard to the essential facts.

The extent to which medical care is actually received depends largely, although not only, on ability to pay. This is contrary to American ideals, which call for equal service to all according to need. In general, persons in the high-income brackets receive

relatively much more service — and in many cases better care — than do those in the middle-income and low-income groups, although the need for service tends to increase with decreasing income. The proverbial statement that the rich and the poor receive good service is correct with respect to those of the former who have chosen their parents well and consequently do not have to worry about their sickness bills and for those of the latter residing in large cities and for those living outside large cities when they need hospitalization.

Until a few years ago there was a large group of forgotten men and women — the self-supporting persons with low and moderate incomes. It is of great significance that the picture has begun to change since the development of voluntary health-insurance plans. There is accumulating a large body of evidence showing that the removal of the economic barrier between those ready to render service and those demanding medical care eliminates much of the inequality of service so typical of earlier times. A pertinent example is afforded by the experience of Blue Cross plans. The studies of the Committee on the Costs of Medical Care,⁴ based on the famous investigation by Roger I. Lee and Lewis W. Jones, arrived at the conclusion that 107 admissions per 1000 population would be necessary to provide satisfactory hospital care. Actually, the average number of admissions among the 20,000,000 persons covered by Blue Cross plans is 107 per 1000 eligible persons. It should be borne in mind that the majority of the subscribers to the Blue Cross belong to the middle-income group and before the initiation of insurance programs received only half the amount of hospital care that they now obtain. Twenty million persons constitute only a fraction of the total population, however, and the situation in general leaves much room for improvement. According to the United States Public Health Service,⁵ in 1942 the civilian population of the continental United States obtained in non-federal general and allied special hospitals care equivalent to 0.92 days per person. This compares with 1.4 days believed to be necessary. In Massachusetts, the number of days of hospitalization was 1.4 per person per year, but in Mississippi it was only 0.3.

The gap between the volume of service actually received and the standards of good medical care is much greater if service outside the hospitals is considered. In 1945, about 5,000,000 persons were enrolled in voluntary prepayment plans covering physicians' services and the majority were eligible for limited service only. In many rural areas and small communities professional service is received only in emergencies. In dental care, the extraction of teeth is the service most frequently performed, and conservation of the teeth and prophylaxis play a distinctly minor role.

The question of adequacy or inadequacy of medical care has been, and still is, the subject of heated

discussions. Some medical authors have consistently denied that there is much inadequate medical care. The results of the Selective Service examinations came as a shock to those who had been doubting Thomases, but did not surprise those who had closely studied the many surveys of health conditions in various economic groups and in urban and rural areas. By April, 1945, nearly 5,000,000 male registrants, or 30 per cent of those examined, had been classified as unfit for military service. Of the young women applying to the Women's Army Corps, over one third had been rejected because of physical and mental defects. As Dr. Roger I. Lee⁶ has remarked, the figures are sobering. However one interprets these data, it is certain that the health conditions of these young men and women in the prime of life are nothing to be proud of. In this connection it deserves mention that a total of 1,500,000 young men inducted with defects were readily rehabilitated for military service, and this experience clearly proves that much can be achieved by providing for more and better medical care.

What, then, are the major reasons for the existing inequality of service? Many persons go without adequate medical care because they lack the money to pay for it and are unwilling to accept charity. Some do not seek it because they are not health-conscious or prefer to rely on the drug clerk, an almanac or the advice of the old woman next door. Still others do not desire the services readily available to them, believing that they will not get their money's worth. Everyone knows that there is illness and defect for which little can be done in the light of present knowledge, but it should be realized that there is also much illness and defect for which much could be done.

COST OF MEDICAL CARE

There is need for organization of group payment for medical care. Authors writing for popular consumption often refer to "the romance of medicine." The story of the advance of medical science does read like fiction, but unfortunately there is another side to this picture, hospital bills and doctors' charges are nonfiction.

The rise of scientific medicine has greatly increased available knowledge and skill and made medical care more efficient than ever. With this, medical care has become more complex and more expensive. Profound economic and social changes have had a strong bearing on need, demand and ability to pay for all the services that modern medicine has to offer, with the result that the gap has been widening between medical science and medical practice.

The actual medical expenditures of a large fraction of the population are insufficient for adequate care, and they are ill related to the actual needs. People spend primarily on such services as are

readily available and economize on those that cannot be easily obtained. They are inclined to make certain expenditures that would not be necessary to the same extent were there a complete program of medical care. Proportionately, medical-care expenditures do not figure largely in the total expenditures of the average family. The patient who has to carry the full burden of costs when they occur, however, finds neither consolation nor help in the knowledge that the average costs of medical care represent a small fraction of the expenditures of all families. What matters to him is that he has to pay for the service. Medical costs are unpredictable, unbudgetable and often unbearable. As the head of a family of four with a combined family income of \$1800 once remarked, "If I get sick I go broke paying the hospital and doctors. Then I worry so that I get sick again."

The full benefits of scientific medicine cannot be reaped unless available knowledge and skill are applied to all the people, and this implies the development of organized payment plans designed to make the costs of medical care predictable, budgetable and bearable. We cannot afford not to develop organized payment plans, because they serve the interests of all — the patients, the health professions, the hospitals and the Nation. The average expenditures of all families and individuals for medical care are fairly constant and in recent years have constituted 35 to 40 per cent of their incomes. The country as a whole spends 4 per cent of the national income on all health services. This money, if spent wisely, can buy more and better service for all.

DISABILITY

There is need for protection of the individual and the family against economic losses resulting from disabling illness. Serious disease brings with it not only high expenditures for professional and institutional services but also substantial losses in income, depletion of savings or both. As stated by a California Senate committee,⁷ "Under the present system a siege of sickness brings many families to bankruptcy."

Provision of medical care alone cannot solve all the problems of the sick. Protection of the patient from want caused by reasons beyond his control is a fundamental function of any organized social order based on moral principles. Moreover, quick and thorough restoration of health can be accomplished only if the patient is able to maintain a reasonably fair standard of living during the time he is prevented from working and earning. Provision for the financial support of those temporarily disabled by illness must go with any medical-care program if waste of money and effort is to be avoided. Provision for persons with long-term disability is a necessary part of a comprehensive social-security program.

MEDICAL RESEARCH

There is need for broad and deep research in medicine, its underlying sciences and its social use. In the past, research in the cause, prevention and treatment of disease depended largely on support from endowment income, gifts and foundation grants. Powerful indeed was the influence thus exerted on medical research, and great were the accomplishments of those research workers fortunate enough to obtain some modest support for important projects. But all too often long-term fundamental research in clinical medicine and the basic sciences had to be sacrificed for short-term and fragmentary research, if not solely for confirmatory studies or barren projects. Studies of prime importance had to be discontinued prematurely because of lack of money, whereas studies of secondary importance were carried on because they were financed by earmarked funds. Preoccupied with clinical studies, most of the medical schools neglected research in the socioeconomic aspects of illness and of medicine. Institutions other than the prominent universities found it difficult to develop adequate research programs. Many gifted research workers, unable to afford the financial and personal sacrifices expected of them, left institutions of higher learning to accept positions with industrial companies or other organizations willing to give them both the opportunity to concentrate on their chosen fields and the necessary implements.

As Dr Vannevar Bush⁸ has said so well, "Further progress requires that the entire front of medicine and the underlying sciences of chemistry, physics, anatomy, biochemistry, physiology, pharmacology, bacteriology, pathology, parasitology, etc., be broadly developed." To this list one may add the socioeconomic and psychologic aspects of illness and the socioeconomic aspects of medicine.

The constant and rapid increase in the cost of medical research, coming at a time when the old sources of income are dwindling, has thrown the whole problem into sharp relief. The experience during the war has clearly shown how it can be brought closer to a satisfactory solution. It is now widely recognized that substantial support from tax funds is necessary if research in medicine, its underlying sciences and its social use is to be developed as intensively and extensively as it ought to be at the threshold of the atomic age. Intelligent co-operation is needed in establishing an adequate research program: voluntary organizations, public agencies and individuals must be brought together in the place of reliance on the isolated efforts of a

few organizations and some philanthropists, and international co-operation in research must be fostered. Since the fateful day of August, 1945, on which the atomic age was ushered in, it has become clear to all but those trying to escape from reality that the development of a better social and economic order depends largely on the international co-operation of the intellectual workers and scientists. One may well paraphrase an old rallying cry by saying, "Scientists of the world, unite!" This is the banner we must hold high in the future.

MEDICAL EDUCATION

There is need for support of undergraduate and postgraduate medical education. The future physician should be competent in health guidance as well as in the diagnosis and treatment of disease. He should also have an understanding of the socioeconomic relation of his profession and be able to participate in the formulation and operation of health programs.

Reorientation of the curriculums of medical schools along these lines is in process. The development of broad and effective teaching programs requires full-time teaching, and this means additional funds to provide the medical schools with men of high caliber who are ready to make teaching a career.

Not less important is a new policy in regard to the selection of students of medicine. At present, many promising young men and women find it difficult, if not impossible, to study medicine because they lack the money for the long period of education. The available scholarships are few. Moreover, there seem to be medical schools that restrict the number of students from certain groups. This impression was confirmed by recent events in the state of New York. In regard to adequate educational provisions for Negro students, the record is anything but unblemished.

The great upheaval of the war has brought with it a wave of enthusiasm for reinterpretation of democratic concepts. The training program of the armed services, whatever may be said against it, certainly had one excellent feature. It made it possible for qualified young men without resources of their own to study medicine. This is democratization of education, and from this principle there should be no retreat. If the individual is to be given the freest possible play for his talents, a large number of adequate scholarships must be provided for promising young men and women planning to enter the medical profession.

DEMOCRATIC IDEALS

The task now facing this country is gigantic. It is beyond the power and the financial resources of any individual, any single group or any single state, and requires nation-wide effort for its execution.

In reviewing the facts, repeated reference has been made to the relation of the various problems to democratic ideals. To give this presentation its proper perspective a few remarks may be added on the philosophy underlying the present movement for a national health program.

The Virginia Bill of Rights of 1776 stated that all men have certain inherent rights, namely, "the enjoyment of life and liberty, with the means of acquiring and possessing property and pursuing and obtaining happiness and safety." The Declaration of Independence, enunciating the fundamental democratic tenet that men possess the natural rights of life, liberty and the pursuit of happiness, did not go so far as the Virginia Bill of Rights. By tacit consent, however, the words of the Declaration of Independence have been interpreted as including the right to obtain health service.

With the evolution of democratic thought its individual doctrines, particularly those of equality, freedom and social justice, have assumed new meanings. Abstract objectives are being redefined and clarified in the light of the needs and potentialities of the present civilization. A growing number of statements include in the fundamental human rights the right to medical care. A report made in 1939 by a Senate subcommittee states⁹

The ideals and principles of American democracy call for equality of opportunity. Such equality of opportunity certainly cannot exist unless all groups in the population have access to those health services needed to prevent and cure disease, and to promote vitality and well being.

There is nobody in this country who would object to this statement. The difference of opinion arises when the methods of social action come up for discussion. Some people question the feasibility of over-all planning for health service, talking deridingly of "planomaniacs" or flatly refuse to accept any change in existing patterns. Those holding such opinions should remember Thomas Jefferson's words:

I am not an advocate for frequent changes in laws and constitutions. But laws and institutions must go hand in hand with the progress of the human mind. As that becomes more developed, more enlightened, as new discoveries are made, new truths discovered and manners and opinions change, with the change of circumstances, institutions must advance also to keep pace with the times.

OSSEOUS SYPHILIS*

Report of a Case

MARK EXLEY M.D.,† AND A W. NEWTON M.D.‡

UNUSUAL and extensive involvement of the osseous system by syphilis occurring thirteen months after the appearance of the secondary skin manifestations is indeed of interest. It is known that wide dissemination of spirochetes through the body tissue occurs within three or four hours after the initial infection. Even though the bone, with its periosteum and blood-forming marrow cavity, contains myriads of spirochetes, skeletal involvement is comparatively rare.

Much has been written by the earliest syphilologists vividly describing the symptoms—the pathognomonic osteopathic pain and bony swelling that occur in skeletal syphilitic involvement. The case reported herein is that of a patient who suffered a spontaneous pathologic fracture.

F. B. (No. 62,490), a 26-year-old man, entered the hospital on December 28, 1942, complaining of progressively increasing pain in the right arm and both thighs of 3 weeks' duration.

FIGURE 1 Two X-Ray Films of Right Upper Arm (December, 1942)

The humerus shows beginning bony destruction and marked periosteal elevation.

FIGURE 2 X-Ray Films of Lower Legs (December, 1942)

There is a marked osteitis of the midportions of both tibiae, with moderate periosteal elevation.

was an irregular raised area on the surface of the midportion of the right humerus, which was tender on palpation. Tenderness could be elicited over the entire length of both femurs. There were marked thickening and irregularity and tenderness of the left tibia.

The red-cell count was 3,500,000, the hemoglobin 9.3 gm., and the white-cell count 7300. The Kahn reaction was + + + +, and an Eagle test was positive.

X-ray examination on admission revealed a large area of destruction at the junction of the middle and distal thirds of the right humerus (Fig. 1). There was marked periosteal elevation, with erosion of the bone. A reaction zone was present. The left lower tibia (Fig. 2) showed marked osteitis involving the midportion of the shaft. There was definite erosion of the bones with reaction zones about them. There was moderate periosteal elevation. The femurs (Fig. 3) showed remarkable change. There was tremendous proliferation in the midportions of both bones. Definite erosion was present, and the involved areas were indistinct and had the appearance of ground glass. The clavicles were normal.

The patient absented himself without leave before further studies could be made of the skull and chest and before treatment could be instituted. He re-entered the hospital in January, 1943, but again left on the following day before

and of loss of strength, extreme weakness and general malaise. The past history revealed the usual childhood diseases. There had been no injuries or operations, and venereal disease was denied. The patient developed a rash 13 months previous to admission. His physician told him that he had a "positive blood reaction" and advised him to take treatment. The

any further investigation could be performed. He entered the hospital for the third time on July 24, complaining of severe pain through both thighs, the right arm and the forearm, especially at night. He had recently fractured right arm by bumping it against a chair. The arm thereafter became swollen and painful on movement.

Physical examination revealed a poorly nourished, chronically ill man with a marked pallor. He was depressed, unco-operative and unable to walk without aid. The pupils and fundi were normal. The heart and lungs displayed no

mycosis, but it was decided that the bony changes were syphilitic.

Specific treatment was instituted, consisting of bismuth subsalicylate every 5 days and potassium iodide. Mapharsen was given following the bismuth in gradually increasing doses once weekly. A moderately severe Jarisch-Herxheimer reaction was apparent following the first injection. The patient complained of severe pain corresponding to the areas of bone involvement, but this pain disappeared in 24 hours.

After 2 months of therapy, x-ray examination was repeated. The periosteal elevation present in the films of both ulnas on July 30 had disappeared. The bone destruction in the left ulna had persisted, but the reaction zone about the lesion had decreased. The film of the right humerus (Fig 6) showed that the fracture had healed in good position and that the eroded bone was filling in well. The entire process in both femurs (Fig 7) showed evidence of beginning involution. There were marked irregularity and thickening of the distal portion of the left tibia (Fig 8).

After approximately 4 months of treatment the patient again absented himself without leave, and all attempts to contact him for further study have proved futile.

DISCUSSION

The areas of the skeletal system most frequently involved in osseous syphilis are the cranial bones, the tibia and the shoulder girdle, especially the

FIGURE 7 X-Ray Film of Thighs (September, 1943)
The lesions in both femurs are beginning to involute following therapy.

FIGURE 8 X-Ray Films of Lower Legs (September, 1943)
Both tibiae show considerable improvement following treatment.

change. The spleen was palpated on deep inspiration. The reflexes were physiologic. The skin was clear. There was no adenopathy. There was extreme tenderness with no associated sense of heat over the middle third of the right humerus. There was definite deformity of the carrying angle. The midportion of the left ulna appeared bowed and tender. Both femurs felt thickened and were moderately tender. The red-cell count was 3,340,000, the hemoglobin 9.4 gm., and the white-cell count 5800, with a normal differential. A Kahn test was + + + +, and an Eagle test was positive. A test for Bence-Jones protein was negative, and the levels of blood calcium, phosphorus and phosphatase were within normal limits. The spinal fluid, including a serologic test, was normal.

X-ray examination of the lungs, heart and great vessels was negative, whereas that of the skull showed numerous circumscribed areas of decalcification in the parietal and frontal bones. The ulnas showed periosteal elevation and bone destruction. The right humerus (Fig 4) exhibited marked extension of the process since the first admission. A fracture was visualized in the midportion. The process in the left tibia had progressed slightly. The femurs (Fig 5) showed extension of the process on the left involving the shaft up to the intertrochanteric region. The periosteum of both femurs demonstrated an onion-skin appearance, which was marked on the right.

The differential diagnosis included tuberculous osteitis, multiple myeloma, osteitis fibrosa cystica, pyogenic osteomyelitis, osteolytic metastatic carcinoma, Hodgkin's disease, leukemia, with its bony infiltration, actinomycosis and blasto-

clavicle toward its medial aspect, but lesions are often observed in the ribs and the sternum.

Histologically, the lesion is usually a periostitis, but there is less tendency toward osteoplastic bone proliferation in early syphilis than during the later stages of the disease. At first, the fundamental process is one of osteolysis, with replacement of granulation tissue. Osteitis, however, is more frequent in early than in late syphilis, and it may assume a

FIGURE 3 X-Ray Film of Thighs (December, 1942)
Proliferative processes are present in the midportions of both femurs

FIGURE 5 X-Ray Film of Thighs (July, 1943)

FIGURE 4 X-Ray Films of Upper Arms (July, 1943)
The right humerus shows a pathologic fracture, which occurred approximately seven months after the patient was first seen. The left humerus is essentially normal

FIGURE 6 X-Ray Films of Upper Arms (September, 1943)
The fracture of the right humerus has healed, and after two months of treatment the eroded bone is filling in well

CLINICAL NOTE

GENERALIZED DERMATITIS FROM PEDICULOSIS CAPITIS*

F. RONCHESI, M. D. T.

PROVIDENCE, RHODE ISLAND

IN a recent article, Morris¹ has called attention to pediculosis corporis as an overlooked cause of ulcers of the legs in middle-aged patients. The present paper emphasizes pediculosis capitis as an overlooked cause of a generalized dermatitis.

The usual descriptions of the dermatitis accompanying pediculosis capitis give as its location the scalp and the neighboring areas of the neck. Not infrequently, however, the eczematoid, prurigo-like dermatitis extends far beyond these limits, in some cases it involves the entire cutaneous surface, as in pediculosis corporis. The main difference is that in pediculosis corporis the patient is likely to be elderly, destitute and homeless, and the dermatitis is actually caused by the biting pediculi, followed by scratching. In pediculosis capitis, however, the patient is usually of school age or slightly older, with access to bathing and clothes-changing facilities, and the dermatitis is self-inflicted, resulting from a neurogenic pruritus originating in the skin of the scalp. One may take exception to the neurogenic explanation, however, and argue that the allergen is carried directly from the scalp to the sensitive skin by the patient's nails.

The sensation of itching noted by the examiner of a lousy scalp is a frequent experience, and one can easily imagine the feeling of the host to the pediculi. If the patient has a sensitive skin, he scratches and scrubs his skin furiously. This does not disturb the pediculi, but produces a body dermatitis that fails to respond to calamine or any other lotion and becomes progressively worse.

In most cases the diagnosis of pediculosis capitis produces a shock to the patient and his parents, and one is often told, "Never mind the nits — just take care of the sores." Treatment must be thorough, since so long as a single nit is present, the dermatitis of the scalp, neck and body will continue. As soon as delousing is complete, however, the dermatitis promptly disappears.

A dermatitis of this origin involving the entire body is found only occasionally, but it must be kept in mind, since otherwise the physician's diagnostic ability will be seriously challenged.

During the last few years I have seen several cases in which the correct diagnosis had been missed. One patient was an eighteen-year-old, married

woman, apparently healthy, whose hair was swarming with pediculi (Fig 1). Another was a fourteen-year-old girl who for over a week had been under the care of an experienced pediatrician for an unrecognized, extremely pruriginous dermatosis. She had had some fever, crying spells and anorexia. Examination revealed pediculi on the scalp, and

FIGURE 1

The upper photograph shows the hair covered with nits and swarming with lice. The lower ones show the generalized prurigo-like dermatitis of neurogenic origin. The lice were limited to the scalp and as soon as they and the nits were removed, the dermatitis promptly disappeared.

the correct diagnoses of pediculosis capitis was easily made. There was a reasonable excuse for failure to detect the presence of pediculi, because the patient had blond hair, in which nits are difficult to identify, especially if they are few in number and are scattered over the scalp.

 Hospital.

diffuse or localized gummatous involvement Sante¹ states that the cortex gradually develops a dense, thickened irregularity and that this is seldom attended by reaction of the periosteum Part of the pathologic and anatomic changes due to syphilis are distinctly and characteristically gummatous There are, however, other changes that are similar to those found in chronic inflammation of the bone produced by other causes, the distinguishing point between the two processes being the comparative mildness of the manifestations of syphilitic involvement

Pathologic fractures are not infrequent, but in most cases they appear to be associated with neurogenic syphilis rather than with syphilitic involvement of the bone In the present case, the cerebrospinal-fluid examination was negative It is not surprising that pathologic fractures are relatively rare when one considers that the usual bony disease process is one of proliferation rather than of destruction This case, however, illustrates coexisting osteogenic and osteolytic processes The fracture described above occurred in an area of destruction

In patients with osseous lesions the initial injection of an arsenical is often followed by an acute exacerbation of pain The pain may last for a period of six to thirty-six hours, but the periosteal reactions rapidly subside This is usually followed by prompt relief of all pain Moore² states that if the involvement of the whole bone is present, the subsidence of the painful symptoms may be gradual, requiring a period of days or even weeks The iodides are unquestionably an adjunct in treatment and are indicated in combination with the heavy metals during the course of treatment Thyroid disease, tuberculosis and intolerance to iodides are the only contraindications to their use Clinical improvement is a better criterion for effective treatment than is the serologic response Roentgenologically,

improvement or lack of improvement depends on the type of bony involvement In the proliferative types, little if any change may be noted, even over a period of many years In a small percentage of cases with demonstrable bone destruction, treatment causes deposition of new bone in the diseased areas Persistence of a positive serologic reaction is of no prognostic importance and does not imply an unfavorable prognosis Likewise, a reversal of the serum reaction to negative offers no guarantee against later relapse The physician should not think of effecting a cure but only of arresting progress The patient should be closely followed for twenty-four months

Finally, the ideals to be achieved are as follows The lesions should be healed, the symptoms relieved, relapse prevented, and the progress of the disease arrested

SUMMARY

An unusual case of osseous syphilis is reported, and certain aspects of the diagnosis and treatment of this disease are briefly discussed

stages of adolescence will be recognized. These will be referred to as prepubescence, pubescence and postpubescence. The term "pubescence" (or the pubescent period) taken in its literal sense refers to the period of time during which the pubic hair is developing. The various criteria by which these three stages may be recognized clinically will, however, receive attention in various sections of this review.

The adolescent period is one during which profound changes take place in physical, physiologic, mental and emotional development. Since the literature dealing with these changes is voluminous and leads into many diverse fields, it will be necessary to restrict the scope of this report in a number of ways. Attention will be limited to physical growth and the principal physiologic changes of interest in clinical medicine. Much attention will be given to the individual or group variations that are encountered in apparently normal persons, but pathologic processes as they affect growth and gross abnormalities of growth will not be considered. Furthermore, it will not be possible to deal fully with the studies of fundamental genetics, endocrinology and ecology to see what light they shed on the causes for the changes observed with growth and development during adolescence. The endocrine glands will be briefly considered from the viewpoint of their development and functioning during this period. Although the study of the hormonal control of the growth processes is a fascinating one, it would require a separate report. A few articles that throw light on the effects of different environmental forces in modifying the progress of adolescent changes will be considered, since they appear to have significance in relation to health and medical care during this period.

LONGITUDINAL STUDIES OF THE GROWTH AND DEVELOPMENT OF NORMAL CHILDREN

Davenport and Boas may be considered to have been pioneers in the movement to arrive at a better understanding of adolescence by repeated observations of adolescents over long periods of time. Davenport¹ established the forms of the average curves for growth in height and weight by this method and demonstrated that a so-called "adolescent spurt of growth" is a characteristic phenomenon. He also clarified the differences between the two sexes in the time and magnitude of this occurrence and emphasized the wide individual variability in these respects.

It is of interest to re-read the paper published by Boas² in 1932 in the light of many of the studies published since that time. He based his conclusions on careful repeated measurements, determination of the age of first menstruation in girls and other data obtained for children attending the Horace Mann School in New York City, some of whom were followed during the succeeding college years. In the

article referred to, he reported many findings that have since been substantiated by workers dealing with larger numbers of children, particularly in regard to size and rate of growth in relation to the period of maximum growth and the age at which the menarche occurs. He introduced the question whether his findings did not imply a different tempo of physiologic changes in different persons, a suggestion that has since been clearly demonstrated. Credit will not be repeatedly given to Boas when considering the many aspects of growth and development for which he deserves recognition, because later work offers more adequate reference material, but the article cited should be looked on as a classic in this field.

At the time of the deliberations of the committees of the White House Conference on Child Health and Protection (1929-1931), interest was aroused in adolescence as a neglected and little understood period. The reports of this conference,³ as well as of one called during this period by the Brush Foundation and Western Reserve University,⁴ revealed many gaps in the knowledge regarding this period. Shortly thereafter, with the financial backing of the General Education Board of the Rockefeller Foundation and the support of other foundations as well as of local institutions, a number of research centers were organized with the primary purpose of following children through their entire adolescence. The purpose was usually to study these children from many viewpoints, but with emphasis on comprehensive personal records rather than on mass statistics. These programs are for the most part still under way, and a large number of reports from these centers have already appeared. Collectively, they give a much clearer concept of the normal course of events and the interrelations between them than would otherwise be possible. The studies here reviewed come from many centers, but the following are the principal examples of this movement for organized research into human maturation: the Brush Foundation, Western Reserve University School of Medicine, Cleveland, the Denver Child Research Council, University of Colorado, the Institute of Child Welfare, University of California, the Adolescent Study Unit, School of Medicine and Institute of Human Relations, Yale University, the Harvard Growth Study, Harvard School of Education, the Center for Research in Child Health and Development, Harvard School of Public Health, and the Co-operative Study of School Children, Harvard University.

The reports of these studies have appeared in various journals, but some of these are not regularly seen by physicians, so that the review of the findings of clinical interest in a medical journal may increase their usefulness. The major reports have appeared in monographs published by the Society for Research in Child Development, National Research Council, Washington, D. C., and in *Child*

The gratification of being able to make an immediate diagnosis in a case of this sort is in contrast to the discouragement experienced in cases of almost daily occurrence in which one is faced with a mysterious dermatosis or psoriasis

SUMMARY

In pediculosis capitis, besides a dermatitis limited to the scalp and neck, one must keep in mind that

not infrequently a neurogenic pruritus is present. This causes a generalized dermatitis, which is sometimes difficult to interpret

MEDICAL PROGRESS

NORMAL GROWTH AND DEVELOPMENT DURING ADOLESCENCE*

HAROLD C. STUART, M.D.†

BOSTON

ADOLESCENCE, according to Webster's first definition, is "the state or process of growing up from childhood to manhood or womanhood," and this is the meaning that will be given to the term in this review. Some confusion is apparent in the literature because a second definition by Webster limits adolescence to a much shorter terminal phase of the developmental period — that is, "the period of life between puberty and manhood."

As examples of the confusion caused by this difference of interpretation, one author refers to the "pubescent period" in girls as that preceding the menarche and the "adolescent period" as that following this event, but in another connection he refers to adolescence as "a period of rapid growth." The term "adolescent spurt of growth" so frequently used in the literature is a misnomer if adolescence begins at puberty, for it is then a preadolescent phenomenon. Another author gives the ages of onset of adolescence in a group of normal children under close observation as 7 3/12 to 13 6/12 years for girls and 10 9/12 to 13 11/12 years for boys. These ages indicate that adolescence is considered by him to include the pubescent period or to begin before puberty, in the sense in which this term is ordinarily employed. According to Webster, puberty is "the state or quality of being first capable of begetting or bearing offspring, which is marked by the maturing of the reproductive organs with the onset of menstruation in the female and the development of the secondary sex characters in both sexes, the period at which sexual maturity is reached." In the light of present knowledge this definition is not tenable, since the onset of menstruation and the attainment of the ability to bear children are

far from identical. The term "puberty" is sometimes used in the literature when referring to girls as synonymous with the menarche or the time of occurrence of the first menstrual period. It is, however, oftener employed as referring to the whole period during which the secondary sex characters are developing, leading up to the menarche. It is of necessity used with a rather indefinite connotation when referring to boys, but in general it indicates the period during which the secondary sex characters are developing. To avoid confusion, the term "puberty" will not be used in this review except when direct reference is made to statements in the literature.

It is difficult to select suitable criteria for the beginning and end of adolescence, but as this review progresses it will become evident that according to the first definition, which is the one accepted here, it covers a long portion, roughly the second half, of the period of development. Adolescence begins and ends much earlier in girls than in boys and in some persons than in others, and the early and late changes indicative of the period occur gradually and are usually not readily observed. As the early indications of sexual differentiation are considered it will become evident that by certain criteria, as, for example, an appreciably increased excretion of sex hormones, an earlier age of onset can be assigned than would be possible if one were guided by the first appearance of clinical signs of sex differentiation. Adolescence ends when functional reproductive capacity is fully established and the child has thus become an adult. Again, the time of arrival at this state is not easily recognized, and it probably differs widely between persons, but the evidence that will be reviewed suggests that it is near to the ages at which boys and girls are usually considered to have reached manhood or womanhood.

For purposes of presentation in this review, three

Although the study of the hormonal control of the growth processes is a fascinating one, it would require a separate report. A few articles that throw light on the effects of different environmental forces in modifying the progress of adolescent changes will be considered, since they appear to have significance in relation to health and medical care during this period.

LONGITUDINAL STUDIES OF THE GROWTH AND DEVELOPMENT OF NORMAL CHILDREN

Davenport and Boas may be considered to have been pioneers in the movement to arrive at a better understanding of adolescence by repeated observations of adolescents over long periods of time. Davenport¹ established the forms of the average curves for growth in height and weight by this method and demonstrated that a so-called "adolescent spurt of growth" is a characteristic phenomenon. He also clarified the differences between the two sexes in the time and magnitude of this occurrence and emphasized the wide individual variability in these respects.

It is of interest to re-read the paper published by Boas² in 1932 in the light of many of the studies published since that time. He based his conclusions on careful repeated measurements, determination of the age of first menstruation in girls and other data obtained for children attending the Horace Mann School in New York City, some of whom were followed during the preceding college years. In the

article referred to, he reported many findings that have since been substantiated by workers dealing with larger numbers of children, particularly in regard to size and rate of growth in relation to the period of maximum growth and the age at which the menarche occurs. He introduced the question whether his findings did not imply a different tempo of physiologic changes in different persons, a suggestion that has since been clearly demonstrated. Credit will not be repeatedly given to Boas when considering the many aspects of growth and development for which he deserves recognition, because later work offers more adequate reference material, but the article cited should be looked on as a classic in this field.

At the time of the deliberations of the committees of the White House Conference on Child Health and Protection (1929-1931), interest was aroused in adolescence as a neglected and little understood period. The reports of this conference,³ as well as of one called during this period by the Brush Foundation and Western Reserve University,⁴ revealed many gaps in the knowledge regarding this period. Shortly thereafter, with the financial backing of the General Education Board of the Rockefeller Foundation and the support of other foundations as well as of local institutions, a number of research centers were organized with the primary purpose of following children through their entire adolescence. The purpose was usually to study these children from many viewpoints, but with emphasis on comprehensive personal records rather than on mass statistics. These programs are for the most part still under way, and a large number of reports from these centers have already appeared. Collectively, they give a much clearer concept of the normal course of events and the interrelations between them than would otherwise be possible. The studies here reviewed come from many centers, but the following are the principal examples of this movement for organized research into human maturation: the Brush Foundation, Western Reserve University School of Medicine, Cleveland, the Denver Child Research Council, University of Colorado, the Institute of Child Welfare, University of California, the Adolescent Study Unit, School of Medicine and Institute of Human Relations, Yale University, the Harvard Growth Study, Harvard School of Education, the Center for Research in Child Health and Development, Harvard School of Public Health, and the Co-operative Study of School Children, Harvard University.

The reports of these studies have appeared in various journals, but some of these are not regularly seen by physicians, so that the review of the findings of clinical interest in a medical journal may increase their usefulness. The major reports have appeared in monographs published by the Society for Research in Child Development, National Research Council, Washington, D. C., and in *Child*

Development, the journal of this society. These publications will be useful to physicians interested in adolescents.

Out of all these extensive studies, reinforced by many special or restricted ones, the substance of only a few can be considered here. Several previous reviews may be consulted by those who wish a more complete bibliography, especially those by Greulich and his associates⁵ and by Shuttleworth,⁶ both published in 1938, and that by Jones and a committee of the National Society for the Study of Education,⁷ published in 1944.

PHYSICAL GROWTH

In studying the growth of children, curves based on averages for each age have some value in showing general trends, but they must be interpreted guardedly, for they tend to mask characteristic differences among various types of persons. This is particularly important in considering growth during the adolescent years, when such wide differences in progress are encountered between those who mature early and those who mature late. A few general features of growth will be deduced from the composite curves before individual and group differences are discussed.

The following brief statement regarding the rate of growth in height and weight by year of age and by sex is based primarily on a recent report by Simmons.⁸ This report gives average figures from repeated measurements taken at the Brush Foundation throughout the adolescent years in a large number of children. The averages obtained from this source may be somewhat advanced for the United States as a whole, since the children enrolled did not represent a true sample of the population but a group representing rather better than average socioeconomic levels. These averages are, however, in close agreement with those obtained for girls by Dearborn and Rothney,⁹ from the Harvard Growth Study, by the Ministry of Health of Canada on Toronto school children¹⁰ and from other extensive sources in the United States, some of which are referred to later in this report. The curves produced by the yearly increments in height and weight obtained by Simmons are quite different from some obtained by workers in other countries or in earlier years—for example, those based on German data reported by Pfuhl in 1928, as presented by Greulich.¹¹ The possible explanations for these differences are briefly discussed below.

Considering only average occurrences, the rate of growth in height—that is, the increment year by year—is continually diminishing from birth to maturity except for a short period that is referred to as the adolescent spurt of growth. The rate of this decrease is rapid during the first two years but diminishes year by year during the preschool period. During the early school years it becomes so slow that the curve of increments appears almost flat.

According to Simmons, girls gain in height at an accelerating rate from nine to twelve years, whereas boys do so from eleven to fourteen years. This results in the fact that girls are taller than boys between eleven and thirteen years. From thirteen years in girls and fifteen years in boys the rate of growth in height decelerates rapidly, and after about three years it ceases. According to these yearly averages, the twelfth year in girls and the fourteenth year in boys appear to be those of maximum growth. As will be seen in connection with more detailed studies of different groups of children, maximum growth actually takes place most frequently at some time during the thirteenth year in girls and the fifteenth in boys, but the inflection in the curves takes place during these years also. It is for this reason that the total gains average less during these than the preceding one for each sex. During the three years of upward trend different groups of children are taking shorter, sharper single spurts of growth at different ages, for reasons which will be discussed, so that the composite curve becomes flattened and broadened. Thus, the child actually grows at a much more rapid pace than the composite curve suggests, but for a shorter period of time.

The average increments for weight by years show a somewhat different picture. Following the initial infantile spurt of growth, deceleration takes place more rapidly for weight than for height, and the increment each year remains about the same between two and five years, a period during which it is smaller than at any other time before maturity. From five years onward there is a slight but progressive increase in gain each year.* This acceleration of gain in weight becomes much more rapid at the time when accelerating growth in height begins, and it terminates at approximately the same time as does that in height, although it tends to be spread over a somewhat longer period. The curves produced by the increments for height and weight for both sexes are reproduced from Simmons's monograph in Figures 1 and 2.

The pattern of linear growth as exemplified in the curves for height is followed in the main by the principal body dimensions and even by the small bones of the hand, as shown by Shuttleworth¹² from measurements taken on roentgenograms. Yet growth is not uniform in the percentage of mature size added in the different dimensions in any given year, or even in the exact age at which maximum growth occurs. Changes in the form and proportions of the body are constantly occurring. In con-

* This gradual rise in the increments for weight from five to ten or twelve years leading up to the major adolescent acceleration has been considered by some investigators to be part of this whole cycle and an early sign that the changes that lead to pubescence are already operating. Linear growth is actually diminishing during this period, however, and the gain in weight may be associated with other factors. In fact, measurements of large numbers of children in other countries or under special conditions fail to reveal a rise during much of this period. Hence, this early rise, as generally shown in the United States may be a manifestation of this country's particular dietary customs and socioeconomic conditions.

formity with the law of cephalocordal progression of relative growth increase, whereas during early adolescence the head has practically completed its enlargement, the lower segment is growing rapidly. Growth in the legs slows down and ceases somewhat before that in the trunk, however, so that the sitting height-stature index, which becomes smaller each year

FIGURE 1 Stature Increment according to Chronological Age (reproduced from Simmons,⁸ by permission of the author)

during early adolescence, reaches a plateau before puberty and is slightly reversed after it. With the use of hip ratios to reveal relative breadth-length growth, it has been found that from about twelve years onward girls become relatively broad-hipped whereas boys maintain a constant ratio. On the other hand, when hip width and shoulder width are

FIGURE 2 Weight Increment according to Chronological Age (reproduced from Simmons,⁸ by permission of the author)

compared, boys are found to progress more rapidly in shoulder breadth, whereas girls progress more rapidly in pelvic breadth. Bayley¹³ has shown that girls exceed boys in pelvic breadths at all ages from eleven to sixteen years, but thereafter the two sexes are nearly alike in this measurement, owing to the generally larger size of boys.* In biacromial

*The development of the pelvis in girls is described in connection with the secondary sex character.

shoulder breadth, girls exceed boys from eleven to fourteen years owing to their general advancement but thereafter boys greatly exceed in this measurement owing both to more rapid general growth and to greater broadening out in this area. These and other differences in rates of growth during adolescence lead to the characteristic differences between men and women in average size, build and contour.

Meredith¹⁴ for boys and Boynton¹⁵ for girls give means for eighteen body measurements for each age up to eighteen years, as well as increments for each of these at the successive age intervals. In subsequent publications these authors^{16, 17} give further anthropometric norms, and Gray and Ayres¹⁸ give norms for some of these measurements based on studies of private-school children. Although many other tables of norms based on studies of large groups of children have been published and are useful as standards, the references cited are as complete and representative as any available for clinical purposes. In Table 1 a few of the segmental and sex differences

TABLE 1 Segmental and Sex Differences according to Year of Maximum Growth

MEASUREMENT	YEAR OF MAXIMUM GROWTH	
	BOYS	GIRLS
Weight	15	12
Height	14	12
Sitting height	15	12
Shoulder breadth (hideloid)	14	12
Pelvic breadth (bi-iliac)	—	13
Hip breadth (bitrochanteric)	14	—
Thoracic circumference	14	11

that emerge during adolescence are revealed by the ages at which maximum growth occurs in some of the principal measurements for each sex, as given by Meredith and Boynton.

INDIVIDUAL VARIATIONS IN GROWTH

Davenport,¹ in the studies previously referred to, called attention to the marked differences between children of the same age — in the age at which the adolescent acceleration in growth begins and ends and in the magnitude of this spurt of growth. Many studies dealing with these differences have appeared since Davenport's description was published. Shuttleworth¹⁹ has shown that when the yearly increments of gain in height for different groups of girls selected on the basis of their ages at the time of maximum growth are charted with the years of maximum growth superimposed, the several curves fit remarkably well but differ in their magnitudes. These studies will be further discussed in considering the relation of this cycle of growth to the menarche. The same applies for the curves of height increments for boys and for those of weight and other dimensions for both sexes. The point of importance to be derived from all these studies is that

children pass through the adolescent phase of accelerated growth at widely different chronological ages, but that in all aspects of growth they follow much the same sequence or pattern for any particular measurement regardless of when the adolescent phase is initiated. Thus, when chronological age is ignored and age of either initial growth acceleration or maximum growth is substituted, there is far greater uniformity between children. Certain differences have, however, been recognized between children taking this growth very early and those taking it very late. Children having early occurrence of maximum growth tend to differ from those having late occurrence in the following ways: the maximum increment is greater in amount, the whole cycle is completed in a shorter time, the children are larger before maximum growth but are likely to be more alike or even shorter at the end because growth is completed more quickly, and maximal growth occurs early rather typically in broad-hipped persons and those with relatively short legs — that is, in those with a feminine configuration.

The actual variability in age of maximum growth is suggested by Shuttleworth's analysis of its occurrence among 174 girls. In 6 cases it occurred between $10\frac{1}{4}$ and $10\frac{3}{4}$ years, and the numbers for each successive six-month age interval were respectively 13, 26, 34, 37, 28, 18, 7 and 5, the last falling between $14\frac{1}{4}$ and $14\frac{3}{4}$ years. In 99 of 174 girls, or more than half, it occurred between $11\frac{3}{4}$ and $13\frac{3}{4}$ years. For boys the distribution was approximately the same but occurred two years later. The stimulus to be advanced or retarded in growth is a general one and affects all dimensions. One may therefore use age of maximum growth, preferably in height, as an indication of the characteristics of a given child in respect to his speed or advancement of growth. In later sections this variability in the timing of growth changes will be related to variability in maturation in other respects.

For correlation with other indices of adolescent development, the significant points about physical growth may be summarized as follows. As shown by average occurrences in groups of healthy children in the United States, the change from a decelerating rate of growth in height to an accelerating one, which marks the beginning of the adolescent spurt, occurs during the tenth year in girls and during the thirteenth year in boys. The change from an accelerating to a decelerating rate occurs in the thirteenth year in girls and in the fifteenth year in boys. A change from a slow to a more rapidly accelerating gain in weight occurs at about the same time as the first inflection in height increments, and a change from an accelerating to a decelerating rate occurs at approximately the same time as does that for gain in height. Second, the change from a decelerating to an accelerating rate of growth in

height — as in most linear dimensions — represents a characteristic stage in adolescent development, and this can usually be recognized when subjects are measured at regular intervals. It is more readily recognized and is more certainly attributable to a stage of development than is the initial stage of adolescent acceleration in gain in weight. The latter is likelier to be a gradual change from slight acceleration to greater increments and is more irregular. Third, the period during which maximum growth takes place is much more easily recognized than is the beginning of acceleration, because the increase in the rate of gain is usually much greater. One cannot be sure that the maximum has been attained until measures of the first phase of deceleration are at hand, but a study of the amounts of gain period by period makes it possible to conclude that the maximum has probably been reached or that the point of inflection in the curve is about to take place. Other physical characteristics, usually associated with maximum growth, described below, help to identify this period. Lastly, the time interval between onset and termination of adolescent acceleration in growth in height averages three years but is usually much shorter for the individual. When children are divided into groups on the basis of the age at which they attain maximum growth, the duration of the period of acceleration for the separate groups averages about two years. Those maturing early may complete this phase in about a year, and late or slower maturing persons usually take considerably longer. The duration of the accelerating period is somewhat longer for measurements of breadth. On the average, the duration of the period of rapid gain in weight is greater than that of growth in height, owing to the influence of acceleration in other measurements that precede or follow that of height.

GROWTH OF PRINCIPAL TISSUES

The adolescent spurt of growth has a far greater proportional magnitude for weight than for height. This is due in part to a tendency to accumulate larger quantities of fat in the subcutaneous tissue during adolescence, a trend that is more pronounced in girls than in boys. McCloy²⁰ used subcutaneous tissue calipers for measuring folds of skin and subcutaneous tissue in conjunction with certain circumferences as aids in interpreting body weight. He gives values for these tissues in various parts of the body by age and by sex, the sex differences in this attribute are strikingly shown in his tables. Stuart and Sobel²¹ in studies of tissue breadths in the calf, as visualized in x-ray films, have shown this same sex difference at all ages up to thirteen years, the latest age for which measurements were available. At thirteen years the thickness of these tissues is increasing at an accelerating rate, indicative of the tendency to accumulate fat during

pubescence. This study shows particularly how enormously persons of the same age differ in this attribute, but demonstrates that any one child tends to have much or little subcutaneous tissue quite consistently at all ages. Fat children, however, tend to be increasingly fat during infancy and in the period of pubescence and less strikingly so during the intervening years. The obesity of adolescence can be looked on in most cases as an exaggeration of a normal tendency, possibly complicated by the particular emotional factors, food habits or lack of activity usual at this time.

The large increase in weight associated with the rapid growth of pubescence is also accounted for in large measure by broadening of the skeleton and increased massiveness of individual bones, which is shown by the incremental curves for most transverse and circumferential measurements of parts where bones are prominent. This increased stockiness of bones becomes much more marked in boys than girls during the late adolescent years, as exemplified by the differences in the growth of the jaws and facial bones in the two sexes. The muscles are also growing rapidly at this time, and this is again more marked in boys than in girls. This accounts for a considerable part of the gain in weight, although members of both sexes differ greatly in this respect. Muscle development is such an important part of normal adolescent progress that it deserves attention from the clinician conducting health examinations during these years. Muscle size, which is being considered here, is only one factor in muscle strength and functional fitness, but it should be assessed in its own right and in relation to the interpretation of body weight.

The measurements of breadths and circumferences for which tables are given by Meredith and Boynton and by McCloy in publications already cited serve particularly to recognize differences in the stockiness of bones and the size of muscles.

The rate of urinary excretion of creatinine may be taken as a measure of muscle weight, hence the curve of increase with age in this excretion can be used as a measure of muscle growth. Talbot²² has estimated that 1 gm. of urinary creatinine excreted in twenty-four hours represents 17.8 kg. of muscle weight. In a study of children in a private school, total twenty-four-hour urinary excretions of creatinine were measured in girls and boys at each age from six through fifteen years.²³ The numbers of children studied were small at all ages, but especially so at six and fifteen years. The variability for each sex at each age was great, but the trend of the means was progressively upward and at an accelerating rate at the older ages. At all ages from six to twelve, inclusive, the boys excreted 10 to 20 per cent more creatinine than did the girls, and at fifteen years the few boys studied showed great individual difference. A few had extremely high

values. The increases by year in both sexes were highly irregular owing to the small samples, but for both sexes combined they were relatively small up to nine years of age, then larger to thirteen years and much larger between thirteen and fifteen years. Although this trend must be confirmed by the study of more children, it is what might be expected from body measurements. At the age of fifteen and thereafter the differences between boys and girls would certainly be expected to increase appreciably. The implication is that maximum growth in muscle mass is a late occurrence, following that of maximum growth in height but contributing to maximum growth in weight.

Dimock²⁴ has studied the development in boys of physical strength and endurance and in motor abilities, using the Rogers test for physical strength or capacity and the Brace test for motor ability or co-ordination. He finds that strength virtually doubles between twelve and sixteen years, but that the peak of increase takes place after the maximum rate of growth in height and weight and during the years of postpubescence. The tests of motor ability or co-ordination showed continuous moderate improvement, but this improvement was more rapid in the prepubescent and postpubescent periods than during the period just preceding that of maximum growth. Dimock's findings did not confirm the widely accepted view that a substantial loss of motor control and resulting awkwardness are associated with the period of rapid growth.

In 1940, Espenschade²⁵ reported the results of motor-performance tests applied periodically to a group of adolescent children being followed at the Institute of Child Welfare, University of California. Because of the extensive observations being made on these children, it was possible to study the relation between motor performance and both physical growth and the evidences of maturity. Six tests of motor performance were used that had been found to be sufficiently reliable, valid and consistent for the purpose of giving evidence concerning co-ordination, strength, speed and accuracy. The mean performance of boys in all tests increased steadily and markedly at each age up to seventeen years, whereas girls failed to improve after fourteen years and in some cases showed a decline thereafter. There were marked individual differences in all tests and in both sexes, but boys on the average surpassed girls in all tests, and this difference increased with age.

This field of study has recently been greatly stimulated by a national realization that an unnecessarily large proportion of American youths are handicapped by faulty development or physical defects at the time when they must begin to assume the responsibilities of adult life. Anyone who has devoted much time to the study of adolescents is familiar with the inactive and generally poorly adjusted youth who eats unwisely and excessively,

takes little exercise and in consequence becomes fat and flabby and performs poorly in tests of physical fitness. It is a pertinent question whether lack of regular physical activity and effort during the years in which muscles naturally enlarge and strengthen rapidly may not lead to permanent underdevelopment in this respect. Adequate but controlled use appears to stimulate muscle development and is probably most effective when muscles are developing most actively. Possibly the likes and habits of girls during these years, since girls are less athletic than boys, lead in part to late sex differences in muscularity. It does appear that psychologic problems in adolescence may have much to do with the rounding out of physical development in this respect and that they deserve attention. Shuttleworth has pointed out that, since the individual adolescent usually passes through the period of rapid growth in about two years, with one period of extremely intensive growth, and not in the less intense and more prolonged manner suggested by the average curves, force is added to the argument for greater attention to food and other needs during this period.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, *Editor*

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 32201

PRESENTATION OF CASE

A sixty-two-year-old Italian-born paint and lacquer sprayer entered the hospital because of abdominal pain.

Two months before admission an ache developed in the right upper quadrant of the abdomen, which was constant and not affected by food, exertion, position or respiration. It became progressively worse, and after a month he was incapacitated by it. Three weeks before admission there was radiation to the right shoulder and right flank. During the illness he maintained a good appetite but lost 10 pounds. There were no gastrointestinal symptoms or changes in bowel habits.

For many years he had had a productive cough, worse in the morning. The sputum was usually dirty brown. There had been no blood streaking.

Physical examination revealed a firm mass occupying the epigastrium. The right border of the mass was nodular, but the left border was round. The liver was not felt separately from the mass, nor was the spleen palpable. The prostate was one and a half times its normal size, slightly tender, soft and symmetrical. There was slight clubbing of the fingers. Except for a soft apical systolic murmur the rest of the findings were normal.

The temperature was 100°F, the pulse 102, and the respirations 24. The blood pressure was 142 systolic, 90 diastolic.

The red-cell count was 3,760,000, with 13.5 gm of hemoglobin. The white-cell count was 10,200, with 78 per cent neutrophils. The urine was normal except for bile in one of three specimens. The stool gave a +++ guaiac reaction. The prothrombin time was 25 seconds (normal, 19 to 22 seconds). In the x-ray film, the right dome of the diaphragm appeared elevated and showed a localized shallow lump in its anterior portion. Each lower lobe of the lungs had a small area of atelectasis. At the right of the lower portion of the trachea and in the right tracheobronchial angle there were two oval masses. A small irregular area of increased density was seen in the third right interspace, and a smaller rounded one in

the left fourth interspace. There was still another nodule beneath the left dome of the diaphragm. In the gastrointestinal series curling of the lower end of the esophagus was described. In addition there were defects said to be consistent with varices, as well as a small hiatus hernia. The second portion of the duodenum seemed to be pressed on by a mass, but this finding was questionable. The colon was normal.

Eight days after admission the patient vomited about 400 cc of dark, reddish-black liquid, which gave a ++++ guaiac test. The stools passed after that day were tarry. Within the next two days the hemoglobin dropped to 9 gm, despite transfusions. There was no other hematemesis. He died on the eleventh day, after a fifteen-minute period during which he was unresponsive.

DIFFERENTIAL DIAGNOSIS

DR JAMES H TOWNSEND Dr Lingley, will you demonstrate these interesting x-ray findings?

DR JAMES R LINGLEY The film of the chest shows two sharply defined masses in the right paratracheal region projecting into the right upper lung field. There is also an area of density in the right third interspace, and a nodule in the left fourth interspace. The diaphragm is distinctly elevated on the right, and in the lateral view the elevation is found to be anterior. The elevation is more sharply limited and more convex than what one usually sees when it is due to a weak leaf of the diaphragm. It suggests a mass in the liver. This film of the lower esophagus shows curling—a series of rounded bulges of the barium-filled lumen. Fluoroscopically these were inconstant, they came and went and were of no clinical significance. Another film of the lower esophagus shows an irregularity of the mucosa that is indicative of varices. I cannot be sure that they are present. The appearance is suggestive but not characteristic.

DR TOWNSEND Do the films give any idea of the size of the liver or of the shape of the lower border?

DR LINGLEY The liver presses the hepatic flexure downward and extends to the notch of the crest of the ilium.

DR TOWNSEND Do they give any indication of an enlarged spleen?

DR LINGLEY The spleen is probably normal in size, but it is not distinct.

DR TOWNSEND There is also a nodule beneath the left dome of the diaphragm. Is that not an unusual place?

DR LINGLEY I cannot see that nodule.

Here are the films of the stomach, and I should like to point out one thing not mentioned in the record. There is a defect on the lesser curvature at this point, and it is important to decide whether it is due to pressure from the left lobe of the liver or to an intrinsic lesion of the gastric wall. From this one film and without fluoroscopy I am inclined to

think that it was an intrinsic lesion of the stomach I do not want to lead you astray, however, and all things being considered, we should probably believe the fluoroscopist, who found nothing wrong with the stomach

DR TOWNSEND To summarize the significant features of this case, this was a sixty-two-year-old Italian who had an interesting occupation in that he used lacquer and presumably various kinds of chemicals and may possibly have encountered something in that occupation that damaged the liver. He had had symptoms for only two months, and the presenting symptom was pain in the right upper quadrant radiating to the shoulder, which suggests something in the diaphragm. In confirmation of this is a lesion shown by x-ray, which apparently involves the capsule of the liver and the diaphragm. He had had a chronic cough with brownish sputum but never any blood. Shortly before death there was a massive hemorrhage from the gastrointestinal tract. The outstanding physical finding is the large nodular liver. We have laboratory evidence that is mainly negative, except that he had a mild degree of normochromic anemia at the time of entry and was showing blood in the stools even at that time. He also had a prolonged prothrombin time, on which I shall comment later.

The x-ray studies give definite evidence of nodules scattered in the chest, below the diaphragm and in the liver. I think that we must assume that there were at least two nodules of considerable size in the liver, one of which projected into the dome of the diaphragm and the other into the epigastrium. It is difficult to offer any explanation of this patient's picture except one on the basis of widespread malignant neoplastic disease, which involved the chest as well as the liver.

What was the origin of this malignant disease? Was it primary or secondary in the liver? What was the probable point at which it arose? I should like to approach the problem from two angles—first, the probable causes of nodules in the liver, and second, the usual causes of massive hemorrhage in the gastrointestinal tract. I shall try to find a reasonable common denominator. I should like to say now that, if this was metastatic cancer in the liver, it would be unusual for lesions of recent origin to produce certain changes that were present in this case. I am going to assume that there were esophageal varices. It would be unusual for metastatic cancer alone to cause enough disturbance in the portal circulation to produce esophageal varices. By the same token it would be rather unusual for a few nodules in the liver to cause enough disturbance of the liver function to produce an increase in the prothrombin time. It would be interesting to know whether this patient showed other evidence of cirrhosis, because metastatic cancer does not usually produce severe damage of the liver parenchyma itself unless it is extremely extensive. Among the

causes of nodules of this sort, however, the most frequent is metastatic malignancy. One must also consider the possibility of a primary malignancy in the liver, which may have arisen from a pre-existing hepatic disease, such as portal cirrhosis. One must also consider other types of liver disease, such as a long-existing hepatitis, originally acute yellow atrophy, with subsequent regeneration, which sometimes takes the form of nodules that can definitely be felt. This possibility is suggested only by the fact that in his occupation he had dealt with various chemicals. One should also consider echinococcus cyst, but I see nothing in this case to suggest that diagnosis. Syphilis can also produce a nodular liver. I do not know what the serologic tests showed in this case, but syphilis would not explain the nodules in the chest, and I shall rule out that diagnosis.

If we look at the problem from the point of view of the more probable causes of massive fatal hemorrhage in the gastrointestinal tract, we should consider such causes as ulcerating malignant neoplasms of the stomach, the duodenum and the pancreas, as well as peptic ulcer, which can produce fatal hemorrhage and can also coexist with cirrhosis of the liver. We should also consider esophageal varices, which are perhaps the most frequent cause of such massive hemorrhage as this patient appears to have had. Also such a thing as a ruptured aneurysm should be considered, but I do not believe that we have enough evidence in this case to suggest that as a possibility. One should also consider a general bleeding tendency, such as that which occurs in the terminal stages of many chronic constitutional diseases. We have no evidence of that, except the increased prothrombin time. There is no evidence of increased bleeding or clotting time.

From the data at hand it is impossible for me to say, at least with any assurance, what was the primary source of this malignant tumor and whether the lesions in the liver were primary or secondary. If they were secondary, such nodules as these usually come from below the diaphragm—from the stomach, duodenum, pancreas or colon or possibly from the prostate. In this case the patient had an enlarged prostate, but it is not described as nodular or stony hard and nothing is said about it to suggest that it was cancerous. Such nodules can also come from primary lesions in the chest. Indeed, in the last case that I discussed here before the war, there was a large nodular liver, quite similar to this, with two nodules in the lungs, it proved to be a primary carcinoma of the lung, which had been asymptomatic.

Arguing from the fact that this patient appeared to have more liver disease than one would expect from a few nodules, from the presence of esophageal varices, which I believe ruptured and resulted in death and from the presence of a prolonged prothrombin time, I am going to venture an opinion

that this man had liver disease of longer duration than the few months that this malignant disease had existed. My first choice for diagnosis, therefore, is a primary tumor of the liver arising on a pre-existing cirrhosis. I do not believe that that can be backed up clinically, that is, by positive proof during life. As a second choice, I choose metastatic cancer of the liver and lungs, most probably primary in the abdominal cavity, such as in the upper silent portion of the stomach, where it is difficult to demonstrate ulcerating lesions but possibly from the lung. As I have said before, it is impossible to be certain about the point of origin of these malignant tumors.

A PHYSICIAN: There is no mention whether the mass did or did not move with respiration. If we could assume that it did move with the liver it would make a great deal of difference.

DR DONALD S. KING: Dr Townsend remembers a case in which the tumor was primary above the diaphragm with metastases below. The one that I had a few years ago was the other way around — primary in the stomach with metastases to the nodes about the lung roots.

How often does a tumor of the stomach metastasize to the liver?

DR TRACY B. MALLORY: It is quite characteristic. Betting on the wards favored primary cancer in the stomach, with secondary nodules in the liver.

DR CHARLES L. SHORT: If we assume that there was cirrhosis, does that make metastatic cancer less likely? According to statements made in various reports, metastases to a cirrhotic liver are relatively rare.

DR WILLIAM CLARK: In an autopsy done several months ago there was primary cancer of the lung with metastases to a cirrhotic liver.

CLINICAL DIAGNOSIS

Carcinoma of stomach, with metastases to liver and lungs

DR TOWNSEND'S DIAGNOSIS

Malignant tumor, primary in liver, arising from pre-existing cirrhosis with generalized metastases

ANATOMICAL DIAGNOSES

Hepatoma, with metastases to lungs, pancreas, kidneys and mediastinal and retroperitoneal lymph nodes

Cirrhosis of liver

Esophageal varices

Hydrothorax, bilateral

PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy on this patient showed a greatly enlarged liver with large and small tumor nodules jutting out all over the surface. Between the various tumor nodules, however, a few small areas of liver tissue could still be recognized, and

these areas were definitely cirrhotic. Besides the tumor in the liver, the pancreas was found completely replaced by tumor and there were metastases in the lungs. The presence of invasive neoplasm in the pancreas raised doubt at the time of autopsy concerning the nature of the tumor, but there was one point that I think is strong evidence in favor of a hepatoma: when one examined the liver from the posterior surface and looked at the hepatic vein, a tumor thrombus was seen to project from the mouth of the vein into the vena cava, and on examination of the rest of the liver all the hepatic veins were found to be filled with tumor thrombi. There are only two tumors that more or less regularly grow into veins in the form of gross thrombi. Hypermorphoma is one of them, as you know, this frequently fills the renal vein and later the vena cava. Hepatoma is the other, indeed, it is not infrequent for a hepatoma to show growth up the hepatic vein into the vena cava and sometimes directly into the right auricle of the heart, which may become completely filled with tumor. On this basis I thought at the time of autopsy that the liver was the probable primary source of the tumor. Microscopically the sections do not help us a great deal further. They are consistent with a hepatoma but not particularly characteristic of it. The tumor was certainly undifferentiated, so that a positive histologic diagnosis is scarcely possible. To my eye it does look considerably more like a liver-cell tumor than a pancreatic tumor, and I think that the gross anatomic appearance and the massive venous invasion are enough to substantiate the diagnosis of hepatoma based on a pre-existing cirrhosis.

The terminal episode was almost certainly, as suggested, a rupture of an esophageal varix, since the stomach was filled with clotted blood. We were unsuccessful in demonstrating the point of rupture.

DR TOWNSEND: I should like to ask whether these varices can rapidly develop secondary to malignant disease or whether they take time, years, to develop?

DR MALLORY: On occasion we have seen esophageal varices for which we could determine no cause.

DR TOWNSEND: But is it not true that you usually do not see them associated with a liver full of metastatic cancer?

DR MALLORY: Almost never.

CASE 32202

PRESENTATION OF CASE

First admission. A thirty-year-old housewife entered the hospital because of leukorrhea and metrorrhagia of three months' duration.

The patient had had one child, a normal infant born eighteen months before admission after a long, difficult labor. On physical examination there was tenderness in both lower quadrants just above the

think that it was an intrinsic lesion of the stomach I do not want to lead you astray, however, and all things being considered, we should probably believe the fluoroscopist, who found nothing wrong with the stomach

DR TOWNSEND To summarize the significant features of this case, this was a sixty-two-year-old Italian who had an interesting occupation in that he used lacquer and presumably various kinds of chemicals and may possibly have encountered something in that occupation that damaged the liver. He had had symptoms for only two months, and the presenting symptom was pain in the right upper quadrant radiating to the shoulder, which suggests something in the diaphragm. CLINICAL DIAGNOSIS

Carcinoma of stomach, with metastases to liver and lungs

DR TOWNSEND'S DIAGNOSIS

Malignant tumor, primary in liver, arising from pre-existing cirrhosis, with generalized metastases

ANATOMICAL DIAGNOSES

Hepatoma, with metastases to lungs, pancreas, kidneys and mediastinal and retroperitoneal lymph nodes

Cirrhosis of liver

Esophageal varices

Hydrothorax, bilateral

PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy on this patient showed a greatly enlarged liver with large and small tumor nodules jutting out all over the surface. Between the various tumor nodules, however, a few small areas of liver tissue could still be recognized, and

these areas were definitely cirrhotic. Besides the tumor in the liver, the pancreas was found completely replaced by tumor and there were metastases in the lungs. The presence of invasive neoplasm in the pancreas raised doubt at the time of autopsy concerning the nature of the tumor, but there was one point that I think is strong evidence in favor of a hepatoma: when one examined the liver from the posterior surface and looked at the hepatic vein, a tumor thrombus was seen to project from the mouth of the vein into the vena cava, and on examination of the rest of the liver all the hepatic veins were found to be filled with tumor thrombi. There are only two tumors that more or less regularly grow into veins in the form of gross thrombi. Hypernephroma is one of them, as you know, this frequently fills the renal vein and later the vena cava. Hepatoma is the other, indeed, it is not infrequent for a hepatoma to show growth up the hepatic vein into the vena cava and sometimes directly into the right auricle of the heart, which may become completely filled with tumor. On this basis I thought at the time of autopsy that the liver was the probable primary source of the tumor. Microscopically the sections do not help us a great deal further. They are consistent with a hepatoma but not particularly characteristic of it. The tumor was certainly undifferentiated, so that a positive histologic diagnosis is scarcely possible. To my eye it does look considerably more like a liver-cell tumor than a pancreatic tumor, and I think that the gross anatomic appearance and the massive venous invasion are enough to substantiate the diagnosis of hepatoma based on a pre-existing cirrhosis.

The terminal episode was almost certainly, as suggested, a rupture of an esophageal varix, since the stomach was filled with clotted blood. We were unsuccessful in demonstrating the point of rupture.

DR TOWNSEND: I should like to ask whether these varices can rapidly develop secondary to malignant disease or whether they take time, years, to develop?

DR MALLORY: On occasion we have seen esophageal varices for which we could determine no cause.

DR TOWNSEND: But is it not true that you usually do not see them associated with a liver full of metastatic cancer?

DR MALLORY: Almost never.

CASE 32202

PRESENTATION OF CASE

First admission. A thirty-year-old housewife entered the hospital because of leukorrhea and metrorrhagia of three months' duration.

The patient had had one child, a normal infant born eighteen months before admission after a long, difficult labor. On physical examination there was tenderness in both lower quadrants just above the

groin The large, hard cervix was fixed on the left The posterior lip was eroded, and there was a cauliflower shaped mass in the external os Biopsy revealed a Grade III epidermoid carcinoma of the cervix A chest film, an abdominal film and an intravenous pyelogram were normal A program of x-ray and radium treatment was outlined in preparation for surgical excision of the tumor, and the patient was discharged on the third hospital day

Second admission (six weeks later) In the interval the patient had received a total of 3000 r by the million-volt machine directed to the anterior and posterior cervix The vaginal discharge had ceased

On readmission the physical findings were unchanged, except for induration and fixation of the upper posterior vaginal wall, which had not been observed previously One hundred milligrams of radium were sutured in the cervical canal on the second and seventh hospital days, and five 10-mg needles were placed around the periphery and left for a total dose of 2250 millicurie hours after each operation She was discharged on the eighth day

Final admission (eighteen months later) Following her last entry the patient gained weight and vigor and felt well for the first six months She then began to have short episodes of diarrhea, characterized by the passage of five or six liquid mucous and blood-streaked stools daily, which were fairly well controlled by paregoric Two months before admission she became weak and anorexic and had to go to bed Two weeks later she became nauseated and vomited about every other meal By the end of three weeks she had become extremely anorexic and weak The urine was dark, and the stools were light The abdomen felt so bloated that it interfered with respiration on lying down One month prior to admission the patient entered another hospital, where the hemoglobin was found to be 22 per cent and she was treated with eight transfusions After the fourth transfusion, she felt chilly and it was noted that her skin was yellow The remaining transfusions proceeded uneventfully The patient stayed in the hospital ten days and then returned home For about ten or twelve days after its onset the jaundice became deeper and the urine became darker, iron therapy obscured the color of the stool After that the jaundice decreased and the urine was lighter but did not become normal Hemorrhoids had developed within the three-month period before admission The night before admission the patient drank a glassful of water and five minutes later vomited it Five minutes after that she vomited again, the vomitus being light red

On physical examination the patient was emaciated and mildly icteric The heart seemed normal except for a Grade II apical systolic murmur There were flatness, absent tactile fremitus and whispered voice sounds and diminished spoken voice sounds at the right base The abdomen was protuberant

and firm and seemed to be full of fluid The skin of the abdomen was mottled The vagina was contracted and firm The cervix and vaults were obliterated Moderate sacral and ankle edema was present There were external hemorrhoids

The temperature was 98.6°F, the pulse 104, and the respirations 20 The blood pressure was 112 systolic, 70 diastolic

The red-cell count was 2,200,000, with 55 gm of hemoglobin The white cell count was 4800, with 90 per cent neutrophils The urine specific gravity was 1.010, and there was a +++ test for bile Urobilinogen was demonstrated in a dilution of 1:32 The urinary sediment was normal The stools repeatedly gave +++ guaiac tests Other laboratory findings were as follows: total protein, 5.4 gm, with 3.2 gm of albumin and 2.2 gm of globulin, nonprotein nitrogen, 15 mg, van den Bergh reaction, 7.7 mg direct and 10.3 mg indirect cephalin-flocculation test, negative at twenty-four hours and + at forty-eight hours, prothrombin time, 43 seconds (normal, 19 to 22 seconds), phosphorus, 2.5 mg, alkaline phosphatase, 29.7 units; and cholesterol esters, 79 mg On x-ray examination the liver appeared enlarged and the flanks were bulging There was a small ring shadow in the right upper quadrant Both costophrenic angles were obliterated, evidently by small amounts of fluid The right leaf of the diaphragm was irregular and elevated, and there was a translucent area between it and the liver In the lateral projection there was a translucent area between the diaphragm and the liver, as well as a wedge-shaped area of density along the midanterior chest wall, whether the latter was on the right or left could not be determined A barium enema revealed two areas of constriction of the ileum, each 2 cm in length One was approximately 16 cm proximal to the ileocecal valve, and the other 8 cm proximal to the first The colon was normal

On the second hospital day the temperature rose to 101°F and thereafter spiked from 100 to 102°F daily The next day the red-cell count was 1,340,000 Within a week pain developed in the right shoulder and the feet became extremely tender and swollen The esophagus, stomach and duodenum appeared normal in a gastrointestinal series performed at that time A peritoneoscope was introduced, and 2500 cc of yellow ascitic fluid was withdrawn The liver appeared to be large and smooth and contained innumerable blue spots, which were thought to be consistent with passive congestion, the spleen was also enlarged No metastases were seen in the abdomen or pelvis The fluid had a specific gravity of 1.007 and was negative for tumor cells On the fifteenth day pain developed in the right shoulder and axilla, and several hours later 750 cc of red blood was vomited The pain disappeared Three days later 10 cc of blood was vomited There were no other episodes of hematemesis, but many clots

were passed by rectum. Numerous transfusions of whole blood brought the hemoglobin up to 10 gm, but the prothrombin time was not much shortened. The van den Bergh reaction gradually rose to 14.5 mg direct and 18.3 mg indirect, and there was accentuation of the edema of the lower extremities, the superficial abdominal veins became prominent. In the fifth hospital week there was a decided change for the worse. The jaundice deepened, and the abdomen distended with fluid. Edema of the lower extremities and dependent parts became severe. The total protein was 5.4 gm per 100 cc. Pain was constant in the region of the right anterior axillary fold. The superficial veins became more prominent. The liver, which had been felt after the paracentesis for the first time, extended three fingerbreadths below the costal margin and was tender. The spleen was palpable. The breath smelled mousey.

Two weeks later she began to be confused. Six liters of yellow-brown fluid was withdrawn from the abdomen. The van den Bergh reaction was 20 mg direct and 25.9 indirect, and the phosphorus and alkaline phosphatase were 4.1 mg and 73.1 units per 100 cc, respectively. At the end of two months she was stuporous most of the time. She died on the sixty-third hospital day.

DIFFERENTIAL DIAGNOSIS

DR WILMAN RICHARDSON: The total length of life from this woman's first admission was approximately twenty-one and a half months.

I am not going to discuss the treatment of carcinoma of the cervix. I simply wish to point out that she received a considerable amount of radiation, sufficient, I think, in a number of cases to produce real cure. Is that correct, Dr Lingley?

DR JAMES R LINGLEY: Yes.

DR RICHARDSON: "The urine was dark, and the stools were light." I might bring up the question, Was this due to jaundice? It is of some importance. I think that it probably was the onset of jaundice although one cannot be sure.

The hemoglobin was 22 per cent, which is extremely low. If it were a normochromic anemia, the red-cell count would be around one million.

"After the fourth transfusion the skin was yellow." I shall again bring out the point that we had a suggestion that jaundice was present before she was given any transfusions. The timing of the transfusions is not given but I think we can assume that they were given in a relatively short space of time. I do not know whether that is a fair assumption.

A loud systolic murmur in a thirty-year-old woman is not normal, although it is difficult to rule out physiologic systolic murmurs on the basis of the loudness of the murmur.

I wish to emphasize that this woman had a low white-cell count (5000), with 90 per cent neutrophils. That is an unusual finding and is consistent

with severe sepsis. If one had a record of the character of the cells one might be able to say definitely that this was severe sepsis. The reason that it is not in the protocol is that very likely no one looked to see if the cells showed signs of toxic sepsis.

"Urobilinogen was demonstrated in a dilution of 1:32." In a case I discussed recently I brought out the point that this is definite evidence that bile was at least reaching the gastrointestinal tract.

Another thing that I keep talking about is that we are told about guaiac tests on the stools but there is no record about their color. It is even difficult to get to look at one on the ward. It would be of some interest to know whether the stools were brown or clay colored. I take it that they were brown.

There was slight reduction in the albumin-globulin ratio. The quite low reading of the non-protein nitrogen may have been due to the fact that this patient had liver disease. The phosphorus was slightly elevated, and the phosphatase was high.

Perhaps the small ring shadow in the right upper quadrant on x-ray examination suggests gallstones. Let us look at the films now. The area above the diaphragm and these intestinal shadows interest me more than anything else.

DR LINGLEY: On this abdominal film I think that the liver is enlarged. I cannot see the ring shadow that was mentioned in the record. The area of the gall bladder looks perfectly clear. This is the film of the chest showing the area of rarefaction described as being beneath the diaphragm. If it is beneath the diaphragm, it means free air in the peritoneal cavity. I am inclined to doubt this, because I cannot see it in the lateral view. I wonder if the upper line interpreted as diaphragm is not just a plaque-like focus of atelectasis in the lung with normal aerated lung beneath it. These are the films of the colon showing the two areas of constriction in the ileum. They are perfectly smooth and have the appearance of benign strictures.

DR CHESTER M JONES: Could this picture be due to radiation?

DR LINGLEY: Very possibly.

DR RICHARDSON: I think that it is.

Pain in the right shoulder could have been due to diaphragmatic irritation.

We do not know whether this patient received some form of vitamin K, presumably she did. If so, it apparently did not cause a decrease in the prothrombin time. The bleeding that occurred may be explained on the basis of prothrombin lack, it is not necessary to postulate a demonstrable ulcerative lesion. The fact that the prothrombin time was not shortened by blood transfusions would not be remarkable if blood-bank blood, not fresh blood, was used. Blood is not much good to provide prothrombin after forty-eight hours. Would you agree to that, Dr Jones?

DR JONES: I feel the same way. The fresher the blood the better.

DR RICHARDSON Shall we try to explain the entire picture on the basis of one illness and the results of that illness, or do we have to search around for many incidental diseases? In the older age group the latter is often profitable. This was a relatively young person, and it is better to explain it all on one disease if we can. We might go afield, especially if there were gallstones, and think of neoplasm of the biliary system with involvement of the liver, but I shall not bring that in. The other thing that I have already hinted at is the question whether this patient had a transfusion hepatitis. I assume that the jaundice came on before the transfusion or at least appeared too soon afterward to be the result of transfusion, so I shall also rule that out.

We still have to consider the question whether this patient had acute hepatitis or subacute hepatitis going on to liver degeneration. It seems to me that there never was the acute severe febrile onset that so many of these patients with severe hepatitis have. The whole progress of the disease seems to have been chronic, and I shall rule out an acute hepatitis as being by itself the cause of the liver disease. I cannot rule out the possibility of secondary hepatic degeneration.

So then I come back to the fact that this was all the result of a single process, and of course the easiest thing to do is to say that this patient had metastatic disease from carcinoma of the cervix and try to link up the whole thing on that basis. It seems to me that a tumor of the cervix is much likelier, especially at the beginning, to extend locally rather than to produce such a widespread picture, which flared up more or less suddenly. If she had recurrence of the disease in the pelvis, I should have expected that she would have had local symptoms, especially those due to involvement of the ureters, hydronephrosis and that sort of thing. I am therefore inclined to doubt that it was due to carcinoma of the cervix, and that brings up the question Dr Jones mentioned.

Did she have a severe x-ray enteritis or x-ray effect on the bowel? It would seem to me that, considering the amount of treatment that she had close to that area, one might say that this lesion was due to the effect of radiation therapy. This might account for the diarrhea and the gastrointestinal symptoms, but it would not account for everything. The process might have gone on further to produce fibrosis, with ulceration and actual perforation of the bowel. If we suppose that it occurred gradually, so as not to produce generalized peritonitis, it would account for sepsis in the abdomen, which was not discovered. It seems to me quite likely that this patient actually had sepsis in the abdomen, with infection of the portal and mesenteric venous system and multiple small abscesses in the liver.

What more? The patient had a Grade II systolic murmur, which brought to my mind a terminal bac-

terial endocarditis. Many patients with chronic illness, if they have a cardiac lesion, end up with a terminal bacterial endocarditis, and that might account for the wedge-shaped shadow in the lung. I think that this patient might have had an infarction in the lung and that of course might well have come from a peripheral vein, and it might also have come from the heart. I do not want to prolong this discussion. I will say, therefore, that I believe that this patient did not have metastatic disease from the original tumor. I think that she had an x-ray enteritis, as a result of which she had what might be called a septic phlebitis, with multiple liver abscesses followed by secondary liver degeneration, and that she died of liver failure.

DR TRACY B MALLORY Are there any suggestions or alternative diagnoses?

DR WALTER BAUER Why could it not all be explained on the basis of an infectious hepatitis that began before the transfusions were given? The clinical course is not against such an interpretation. I admit that 90 per cent neutrophils in the presence of a white-cell count of 5000 is most unusual, although there have been some verified cases of infectious hepatitis with such a leukocyte count. Although Dr Richardson's diagnosis may be correct, we must bear in mind other possibilities.

DR JONES I agree with Dr Richardson that this woman was jaundiced before transfusion. She already had a profound anemia, and after eight transfusions she still had a profound anemia. I do not believe that an anemia of that degree was solely on the basis of an ulcerative lesion in the bowel. It could have been, but I doubt it. Another thing that I should like to comment on is the peritoneal fluid that was withdrawn some days before death — some days before she had more abdominal pain, it was a straight transudate, with a specific gravity of 1.007, which is against an inflammatory process in the abdominal cavity. Finally, I think that the signs of pressure or biliary obstruction are striking, even if there is no comment about the color of the stools. The phosphatase is striking. One can get a phosphatase that is high in intrahepatic disease with jaundice, but it is not at all frequent, in fact it is quite unusual. I believe that this points to an obstructive lesion that was extrahepatic.

DR RICHARDSON I meant to mention the phosphatase. I have laid stress on it in other cases but thought that I would throw it overboard this time.

DR J H MEANS I can recall one patient who was here about a year ago who had a good many points in common with this woman except that the patient was a man who did not have a cancer to start with. The rest of the picture was similar, including the blood picture, and at autopsy he turned out to have just what Dr Richardson has described.

DR JONES This degree of jaundice is rather intense for pylephlebitis, and there is no story of chills and fever

CLINICAL DIAGNOSIS

Carcinoma of cervix, with generalized metastases

DR RICHARDSON'S DIAGNOSES

Radiation enteritis

Pylephlebitis

Multiple liver abscesses

Terminal bacterial endocarditis

ANATOMICAL DIAGNOSES

Metastases of carcinoma of cervix to liver, lung and mesentery, with obstruction of vena cava, portal vein, right branch of hepatic artery and hepatic duct.

Esophageal varices, with rupture

Anasarca

Splenomegaly

Obstructions (two) of ileum, due to tumor nodules in mesentery

Jaundice, severe

PATROLOGICAL DISCUSSION

DR MALLORY The autopsy showed that this was entirely due to one disease — cancer of the cer-

vix The surface of the liver, as described at peritoneoscopy, was perfectly smooth, but on section the liver was about 60 or 70 per cent replaced by tumor This tumor had grown directly into the vena cava, and the tumor and secondary thrombosis had produced a complete obstruction of the cava It had also grown down the lymphatic vessels around the portal vein, the common bile duct and the hepatic artery, so that the portal vein, the bile duct and one branch of the hepatic artery were occluded by external pressure of the tumor There were some metastases to the lung, which were probably due to tumor emboli from this mass in the cava The heart, despite the murmurs, was completely negative The ileum was occluded in two spots by kinking around tumor masses in the mesentery It showed no evidence of radiation enteritis

On many occasions in these exercises we have pointed out that metastatic tumor to the liver does not produce portal hypertension In this case the enlarged spleen, weighing 500 gm, and the presence of well marked esophageal varices leave little doubt that it existed The obstruction, however, was apparently not produced within the liver but by the extension of the tumor into the tissues about the hilus, with constriction of the extrahepatic portal vein

NATIONAL HOSPITAL DAY

ON MAY 12 the hospitals of this country observed National Hospital Day. Having satisfactorily met increasing demands on their facilities during the years of the war in spite of curtailments in personnel, equipment and supplies, they are now faced with the tremendous task of furnishing adequate facilities and care to an even greater number of people. As Dr. Peter D. Ward, president of the American Hospital Association has stated:

This does not mean that more people will be ill, but simply that the public has become more hospital-minded. Also, the benefits of Blue Cross have made hospital care available to more people. As preventive medicine has come of age, the hospital no longer signifies a place for final and drastic measures, rather it is a place for health protection, where minor as well as major ailments may find alleviation.

It might be added that still another factor is involved, namely, that miracles in the handling of

certain types of medical and surgical cases have permitted the successful hospital treatment of patients who were formerly told that nothing could be done for them.

Certain of the voluntary hospitals, whose total assets comprise two thirds of the value of all general hospitals in this country, have already made plans for new construction, but many other things must be accomplished to meet this challenge. These include hospital surveys, licensing systems, increased availability of prepaid hospital and medical-care insurance and the establishment of health centers. If a voluntary system of medical care is to continue, these hospitals must have the confidence and the enthusiastic support of the public and the medical profession. Indeed, financial assistance from state governments, supplemented, if necessary, by federal grants-in-aid, will probably be required for the successful accomplishment of this program, which has much to do with the health of the Nation.

SIXTY YEARS OF NURSING SERVICE

It is fitting that the celebration of the sixtieth anniversary of the establishment of the Visiting Nurse Association of Boston, which was held during Public-Health Nurse Week in April, should receive recognition by the medical profession.

Beginning in 1886, under the name Instructive District Nursing Association, with two nurses, it was employing one hundred and fifty nurses on its fiftieth anniversary, and it has always found opportunities far greater than its financial support has justified an attempt to meet. Throughout these years it has been a most valuable and valued ally of the medical profession and has demonstrated in its own field the indispensable nature of the contribution of the public-health nurse, not only in caring for the sick but in advancing civilization through the prevention of disease.

True to its central purpose, as the original name made explicit, it has been an educational institution, and although the first approach is through the bedside nursing of patients who, except in emergency, are under the supervision of a physician, its unit of major interest is the family. It renders family health service. Here an important approach is by

of problems of individual and family nutrition, and this raises the question of making, using and saving to a budget. Although this aspect of the work is time-consuming, fundamental lessons in household economics are taught.

The Association renders a community service to people of all classes. About 15 per cent of the patients pay the full cost, and 7 per cent pay part of the cost. The full cost in 30 per cent of the cases is paid for by certain insurance companies. In slightly less than 50 per cent of the cases no money is collected. Since the establishment of the Boston Community Fund, the Association has been a participating agency.

It started the first school in the United States for the training of visiting nurses, which was later taken over by Simmons College, and it continues to offer an opportunity for field work to students. Its work is carried on all over the City of Boston, and last year a total of 155,200 calls were made on 22,885 persons. It employs supervisors specially trained in nutrition, mental hygiene, social hygiene, occupational therapy, physical therapy and maternity care and in the administration of its twelve districts. Although the number of cases given care at confinement is relatively small, since so many patients go to hospitals, prenatal care was administered to 5000 women during the past year.

The scope of the Association's work cannot be described briefly, and it is impossible to measure the benefits of the ministrations of its devoted nurses through these sixty years. We congratulate the community on having in its midst such a strong and vigorous organization, and we extend, on behalf of the medical profession, best wishes for even greater usefulness in the future.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

GUNTER — Fred C. Gunter, M.D., of Belmont, died April 24. He was in his fifty-fifth year.

Dr. Gunter received his degree from Tufts College Medical School in 1914. He was a veteran of both world wars. He was a specialist in internal medicine, being particularly interested in cardiac diseases, and was formerly chief of staff of the Robert Breck Brigham Hospital, of Boston. Dr. Gunter was on the courtesy staff of the Brooks Hospital, Brookline, and was a fellow of the American Medical Association.

His widow, a son and his mother survive.

METZGER — Butler Metzger, M.D., of Lynn, died April 25. He was in his seventy-third year.

Dr. Metzger received his degree from Harvard Medical School in 1897. He was on the staff of the Union Hospital, Lynn. He was a fellow of the American Medical Association.

*Made reportable December, 1943

†Four year average

COMMENT

Diphtheria, German measles and pulmonary tuberculosis were reported at figures above their seven-year median. The slight increase in the last is undoubtedly attributable to state-wide case-finding programs. Salmonella and bacillary dysentery cases were also reported at higher figures. Dog bite reached a record high figure for the month. The high incidence of malaria is due to its appearance in veterans from malaria-infested zones.

Reported at a record low figure was lobar pneumonia. Measles was reported at a figure below the seven-year median, in spite of a marked national increase. Also at figures below the seven-year medians were chicken pox, mumps, scarlet fever, whooping cough and meningococcal meningitis.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Actinomycosis was reported from Holyoke, 1, Lawrence, 1, Malden, 1, total, 3.

Anterior poliomyelitis was reported from Everett, 1, Spencer, 1, total, 2.

Diphtheria was reported from Boston, 10, Cambridge, 1, Dracut, 1, Falmouth, 1, Ipswich, 1, Lowell, 1, Medford, 1, Melrose, 2, Taunton, 2, total, 20.

Dysentery, bacillary, was reported from Boston, 1, Marblehead, 1, Wrentham (State School), 12, total, 14.

Encephalitis, infectious, was reported from Worcester, 1, total, 1.

Malaria was reported from Boston, 11, Brockton, 2, Brookfield, 1, Brookline, 1, Cambridge, 4, Chelsea, 1, Dartmouth, 1, Gardner, 1, Holbrook, 1, Holliston, 1, Lawrence, 1, Lynn, 1, Malden, 3, Medford, 2, New Bedford, 1, Newton, 2, Peabody, 3, Pittsfield, 2, Quincy, 1, Rockport, 1, Somerville, 2, Springfield, 2, Stoneham, 1, Stoughton, 2, Tyngsboro, 1, Waltham, 1, Waltham Regional Hospital, 1, Warren, 2, Westfield, 1, Worcester, 7, total, 62.

Meningitis, meningococcal, was reported from Boston, 4, Brockton, 1, Clarksburg, 1, Everett, 1, Fall River, 1, Lawrence, 1, Lowell, 1, Medford, 1, Somerville, 1, total, 12.

*Made reportable December 1943

†Four year average

COMMENT

Diphtheria, German measles and pulmonary tuberculosis were reported at figures above their seven-year median. The slight increase in the last is undoubtedly attributable to state-wide case-finding programs. Salmonella and bacillary dysentery cases were also reported at higher figures. Dog bite reached a record high figure for the month. The high incidence of malaria is due to its appearance in veterans from malaria-infested zones.

Reported at a record low figure was lobar pneumonia. Measles was reported at a figure below the seven-year median, in spite of a marked national increase. Also at figures below the seven-year medians were chicken pox, mumps, scarlet fever, whooping cough and meningococcal meningitis.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Actinomycosis was reported from Holyoke, 1, Lawrence, 1, Malden, 1, total, 3.

Anterior poliomyelitis was reported from Everett, 1, Spencer, 1, total, 2.

Diphtheria was reported from Boston, 10, Cambridge, 1, Dracut, 1, Falmouth, 1, Ipswich, 1, Lowell, 1, Medford, 1, Melrose, 2, Taunton, 2, total, 20.

Dysentery, bacillary, was reported from Boston, 1, Marblehead, 1, Wrentham (State School), 12, total, 14.

Encephalitis, infectious, was reported from Worcester, 1, total, 1.

Malaria was reported from Boston, 11, Brockton, 2, Brookfield, 1, Brookline, 1, Cambridge, 4, Chelsea, 1, Dartmouth, 1, Gardner, 1, Holbrook, 1, Holliston, 1, Lawrence, 1, Lynn, 1, Malden, 3, Medford, 2, New Bedford, 2, Newton, 2, Peabody, 3, Pittsfield, 2, Quincy, 1, Rockport, 1, Somerville, 2, Springfield, 2, Stoneham, 1, Stoughton, 2, Tyngsboro, 1, Waltham, 1, Waltham Regional Hospital, 1, Warren, 2, Westfield, 1, Worcester, 7, total, 62.

Meningitis, meningococcal, was reported from Boston, 4, Brockton, 1, Clarksburg, 1, Everett, 1, Fall River, 1, Lawrence, 1, Lowell, 1, Medford, 1, Somerville, 1, total, 12.

Meningitis, Pfeiffer-bacillus, was reported from Everett, 1, Petersham, 1, Springfield, 1, Wareham, 1, total, 4

Meningitis, pneumococcal, was reported from Fall River, 1, Lynn, 1, Marblehead, 1, Winthrop, 1, Worcester, 1, total, 5

Meningitis, other forms, was reported from Phillipston, 1, total, 1

Meningitis, undetermined, was reported from Camp Edwards, 1, Nantucket, 1, total, 2

Salmonella infections were reported from Boston, 2, Granby, 1, Lynn, 1, Newton, 1, Revere, 1, Southampton, 2, total, 8

Septic sore throat was reported from Attleboro, 1, Boston, 7, Medford, 1, Merrimac, 2, Newton, 1, Orange, 1, Williamstown, 1, total, 14

Trachoma was reported from Milton, 1, total, 1

Trichinosis was reported from Adams, 3, Boston, 1, total, 4

Typhoid fever was reported from Fall River, 1, Lawrence, 1, Norwood, 1, total, 3

Undulant fever was reported from Adams, 1, East Longmeadow, 1, Melrose, 1, Nantucket, 1, Southbridge, 1, total, 5

of Walter Dodd and of the late "Joe" Godsoe, — his assistant at that time, — who died on February 8

I well remember an incident that may have been prophetic. On the morning after Walter Dodd made his first experiments with the Crookes's tube he gave a brief demonstration with the fluoroscope before several physicians and surgeons who were attached to the hospital at that time. Among them was the late Dr. Maurice Richardson who, after looking at his hand, pulled out an old wallet from his hip pocket, held it in his hand before the fluoroscope and remarked, "I think that I can see more in this than I had realized," still holding the purse. We laughed, of course, thinking that he was referring to the amount of cash in coins in the purse, but I have since wondered if he were not looking much farther ahead than we realized at the time.

MISCELLANY

NOTES

The Boston Surgical Society awarded the Henry Jacob Bigelow Medal to Dr. Frank H. Lahey on May 10. Dr. Lahey gave an address entitled "Surgery of the Thyroid," following which he was presented with the Bigelow Medal by the president of the society, Dr. Donald Munro.

The Board of Managers of the Quincy City Hospital have recently announced that Dr. Ensio K. F. Ronka was appointed director of the hospital on April 1.

CORRESPONDENCE

MORE ABOUT BACTERIOLOGIC LABORATORIES

To the Editor: I was much interested in the letter from Dr. Wails, Commissioner of Health of Worcester, Massachusetts, regarding health department bacteriological laboratories, which appeared in the March 14 issue of the *Journal*.

It might be interesting to your readers to know that the City of Boston started the examination of throat cultures for diphtheria in November, 1894. During that and the following month, 1002 cultures were examined, with 246 positives. This work was performed at the Harvard Medical School by Dr. McCollum, physician to the Board of Health. The 1894 report reads, "All physicians were invited to take cultures from throats where diphtheria was suspected, and for their convenience, culture tubes in cases were provided and stations were established at drugstores, where physicians could obtain tubes for cultures." Ten stations were established, one of which is still in existence.

November, 1894, also saw the beginning of the manufacture of diphtheria antitoxin by the Boston Health Department. This work was performed on Gallup's Island, in Boston Harbor, by Dr. Harold Ernst, of Harvard Medical School, assisted by Dr. C. G. Page and Dr. S. A. Hopkins. It was not until 1898 that the Commonwealth took over this work.

When I first read Dr. Wails's letter, without annual reports at hand, it immediately came to mind that perhaps Boston had a little something on Worcester, but as can be gathered from this letter, the Oscar will have to be given to Worcester by two months.

CASE 32211

PRESENTATION OF CASE

A forty-six-year-old carpenter entered the hospital because of abdominal pain and vomiting.

The patient had been in apparent good health until two years before his last admission, when he had a two-day bout of severe crampy periumbilical nonradiating pain accompanied by nausea and vomiting. The pain was sudden in onset and required hospitalization for ten days. It bore no relation to meals and was not relieved by soda or food. He was discharged from the hospital on a diet. Eight months later he had a similar episode, which lasted intermittently for about three weeks and was associated with marked constipation. At that time he also had pleurisy and was hospitalized for one month. After discharge he continued to have a cough and to raise sputum, and for these reasons he was admitted to this hospital. A left lower lobe lobectomy was performed at that time for lung abscesses. While in the hospital he had another attack of abdominal pain. Physical examination of the abdomen, as well as a gastrointestinal series and a barium enema, was negative. Following the chest operation another abscess developed in the lungula, which yielded satisfactorily to penicillin treatment. The patient then gained weight and was completely asymptomatic until the month before admission, when he again had two attacks of periumbilical cramps, followed by vomiting after three to four hours. The pain was severe enough to require sedation with morphine. A Graham test, gastrointestinal series and barium enema, done at a local hospital, were reported as negative. At no time were the attacks accompanied by jaundice, melena, diarrhea or hematemesis. The appetite remained fair.

Physical examination revealed a well developed and well nourished man apparently in no acute distress. The heart was normal. The breath sounds were diminished at the left base. The abdomen was tender to pressure in the lower quadrants, but no masses were felt. Peristalsis was normal and active.

The temperature, pulse and respirations were normal. The blood pressure was 128 systolic, 70 diastolic.

Examination of the blood showed a hemoglobin of 12 gm per 100 cc. The white-cell count was 7100. The nonprotein nitrogen was 31 mg per 100 cc. The chloride was 104 milliequiv per liter, and the total serum protein was 5.8 gm per 100 cc. The serum amylase was 30 units per 100 cc. The urine was normal. The stools were guaiac negative on repeated examinations.

X-ray examination of the chest showed the mediastinum retracted to the left. The left leaf of the diaphragm was elevated, and the left costophrenic angle was deformed, apparently by old adhesions. Scattered bits of opaque material remained on the left side, and there were several areas in the left lower chest in which the lung markings could not be traced. A flat film of the abdomen showed a large amount of gas and fecal material in the colon. There were also gas-filled loops of small intestine. A gastrointestinal series with hourly films revealed a rounded extrinsic pressure defect of the duodenal bulb, which was probably due to the gall bladder. The stomach emptied normally. There was a peculiar widening and crowding of the mucosal markings in the jejunum that was somewhat suggestive of an intussusception led by a small tumor mass. A later film, however, showed that the head of the barium column was approaching the splenic flexure, with the barium distributed throughout the right colon and ileum. The jejunum was empty on the four-hour film. The ileum appeared wider and lay lower in the pelvis than usual. A small-bowel enema, done to check on the previous findings, failed to show any abnormality.

The patient continued to have occasional attacks of crampy periumbilical pain and nausea. Another flat plate taken during one of the attacks showed several dilated loops of gas-filled small bowel, with only a small amount of air in the colon.

On the seventh hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. GRANTLEY W. TAYLOR: May we start off by seeing the x-ray films?

DR. RICHARD SCHATZKI: This is a postoperative film following lobectomy. It shows what was described in the report. These are the films of the gastrointestinal series. The report as stated in the record gives an erroneous impression regarding the permanency of the unusual finding in the small intestine. It was actually seen on only one film. The small intestine is widened locally, and its appearance suggests intussusception. The bowel proximal to it is widened, whereas on the earlier and later films taken on the same day there is no evidence of any abnormality, not even widening of the small intestine. These are the films taken at the time of

the small-bowel enema, the lower jejunum was studied particularly carefully, but no abnormality of any kind was seen. The bowel did not appear dilated. Additional films were taken at half-hour intervals over a period of one and a half hours, and again nothing abnormal was seen. A flat film taken on the next day showed definitely dilated loops of small intestine.

DR TAYLOR Dr Schatzki started by showing you the films of the chest, but I shall pass over the lung condition with only a brief comment. It is unfortunate that he developed pleurisy and lung abscesses and had to have an operation, but I cannot see any possible connection between the lung condition and the gastrointestinal tract.

Essentially, we have a patient with recurrent bouts of obstructing pain and vomiting occurring intermittently over a period of years. At the time of his second admission he was described as being a well developed, well nourished man in no acute distress, with slight tenderness in the lower abdomen but no other positive findings. These pains were characterized, at various times, by periumbilical cramps, which were almost invariably associated with vomiting and nausea. At times these attacks recurred at frequent intervals for as long as ten days, but at other times there were periods of remission, when the patient was absolutely free from discomfort and inconvenience, gained weight and was asymptomatic. To me, that type of crampy periumbilical pain, associated with vomiting, is indicative of partial intermittent intestinal obstruction, presumably of the small intestine. The vomiting started fairly promptly after the onset of the pain, and the symptoms eventually passed off by themselves. So we might say that whatever was causing this condition had abated spontaneously at the time of admission. There is nothing in the chart or the recorded appearance to suggest that he had an inflammatory process, such as appendicitis or acute cholecystitis.

The laboratory findings, including the temperature, were strikingly negative. He had a lot of x-ray studies at various times, all of which tended to exempt from suspicion the biliary tree and everything else but the intestinal tract. So we come to the problem of what was causing these intermittent bouts of intestinal obstruction, they appear to have been on a mechanical basis, without impairment of the circulatory state of the bowel. The only evidence that sheds any light on the nature of the process that was doing this is the x-ray observation that Dr Schatzki has just pointed out. What sort of things do leave a man in good health, with no abnormal laboratory findings, with intermittent bouts of certainly distorted bowel but without actual obstruction of the bowel? We always have abnormal bands and kinks and that sort of thing to consider. Since there had been no previous operation, artificially made adhesions could not have caused these

attacks. There is no description of a hernia. Of course, internal hernias are not infrequent, but they do not repeatedly resolve themselves in this fashion without active therapeutic intervention. Meckel's diverticulum is often associated with this type of symptomatology, but there is nothing in the protocol that justifies making the assumption that that condition was present. So we come to the problem of the x-ray condition, whatever it is, as an explanation of his symptomatology. The x-ray people are certainly "handing it to us on a platter" when they say, "There was a peculiar widening and crowding of the mucosal markings in the jejunum that was somewhat suggestive of an intussusception led by a small tumor mass." Even without such a gratuitous offering I think that we might arrive at the conclusion that some such condition was present. Certainly if we entertain the idea of tumor it seems to me that the condition of the patient in relation to the duration of symptoms argues against the presence of malignant neoplasm. When it comes to deciding what sort of benign neoplasm was involved, a histologic examination is required. There are leiomyomas, fibromas, lipomas and other rarer tumors of the small intestine. Someone will say, "What about lymphoblastoma?" That often behaves like a benign tumor in its leisurely progress, with freedom from hemorrhage and cachexia for some time, but after two years' duration there should have been evidence of lymphoblastoma elsewhere.

I cannot do more, Dr Mallory, than to say I believe that this patient had a primary neoplasm of the small intestine, probably benign, the histologic character of which I leave to you. He may have had a dyskinesia that justified the diagnosis of intussusception. Certainly, if he had an intussusception, it resolved itself without gross blood or pronounced clots in the stools, both of which are traditions in intussusception.

DR TRACY B MALLORY Dr Herrera, will you describe what was seen when the abdomen was first opened?

DR RODOLFO E HERRERA We operated because we were convinced that he had had repeated episodes of small-bowel obstruction. When we opened the abdomen, we found throughout the mesentery and omentum innumerable small pale-yellow granules, some of the nodes of the mesentery, in fact most of them, were enlarged and felt soft. In only one region — the midjejunum — was there any invasion of the small bowel. This area somewhat resembled regional enteritis, with thickening of the mesentery and invasion of the bowel wall causing almost complete obstruction. There was great disparity between the size of bowel proximal and distal to this loop. Because of the extent of the process in the mesentery we did not believe that we could cure him, and we entertained the diagnosis of lymphoma or tuberculosis at that time. To establish the diag-

osis conclusively and also since the region of the jejunum seemed to be irreversibly obstructed, we resected the jejunum and did a side-to-side enter-enterostomy.

DR. MALLORY: Would you care to add anything at this point, Dr. Taylor?

DR. TAYLOR: Not a thing. The case is very instructive.

CLINICAL DIAGNOSES

Recurrent intestinal obstruction

Granuloma, small bowel

DR. TAYLOR'S DIAGNOSIS

Benign tumor of jejunum

ANATOMICAL DIAGNOSIS

Malignant lymphoma (giant-follicle type) of jejunum, mesentery and omentum

PATHOLOGICAL DISCUSSION

DR. MALLORY: The pathologist was called in consultation in the midst of the operation. The first specimen was a piece of the omentum, and frozen sections showed a picture that I never happen to have seen before—many isolated lymphoid follicles, all of which were quite separate from one another. We thought at the time that it was a lymphoma of the so-called "giant-follicle type," although we had never seen a manifestation quite like this. When the resected specimen was brought over to the laboratory, a tumor mass was found, as Dr. Herrera has told you, in the small bowel and the adjacent mesentery. Sections of that showed obvious and typical lesions of giant-follicle lymphoma. As perhaps you know, of all the types of lymphoma this is the one that ordinarily runs a relatively benign course. A duration of two years without generalized cachexia is not impossible with this type of lesion. I think that it is fair to assume that this is what he had from the start of his intestinal symptoms. I doubt that it can be tied in in any way with the chest disease.

DR. SCHATZKI: After we knew the cause of the patient's trouble, we went back over the films to see if we could find any evidence of the disease. I could see what appeared to be a tumor on only one film, which was taken at the time the mass had intussuscepted and had produced obstruction. When you know that there is something, it is rather discouraging to look carefully for it and still be unable to demonstrate it.

DR. MALLORY: This man, of course, will get x-ray treatment, and the prognosis is relatively good. The average duration of this type of disease is nearly five years from the onset of symptoms, and he might easily live a number of years in an excellent state of health. We believe, in this hospital, that when there is a lymphomatous involvement of a hollow viscus it is wise to resect it before initiating x-ray

treatment. There is significant danger of spontaneous perforation of the lesion if x-ray treatment is started too vigorously when the intestinal tract is involved. Do you agree, Dr. Schatzki?

DR. SCHATZKI: We have become more courageous but still advocate surgery if it can be done. A single lesion probably offers the best prognosis.

DR. HERRERA: I should like to ask Dr. Schatzki whether he thinks that the diagnosis might have been established if, instead of doing a small-bowel series in the usual way, they had allowed the Miller-Abbott tube to advance and had introduced barium through it.

DR. SCHATZKI: That would have offered a good chance, unless the Miller-Abbott tube had gone through the area of narrowing.

DR. HERRERA: I do not believe that it could have gone through.

CASE 32212

PRESENTATION OF CASE

A sixty-five-year-old Italian mother of ten children entered the hospital because of abdominal pain, nausea and vomiting.

The patient had been in good health until one year prior to entry, when she began to complain of mild upper abdominal discomfort coming on usually in the evening and after meals. There was no vomiting, diarrhea, chills or jaundice. Ten days before entry, following a supper of ice cream and pie, the patient complained during the night of nausea and slight pain in the right lower quadrant, which became generalized by the following morning. She also began to vomit and pass profuse watery stools. After taking some pills prescribed by her local physician, the symptoms abated somewhat but the pain and vomiting of everything taken orally continued until admission.

Physical examination showed a well developed and well nourished woman in no acute distress. The tongue was dry and reddened. The chest was clear except for a few transient rales at the right base. The abdomen was evenly protuberant, soft and non-tender. Peristalsis was active. No masses were felt.

The blood pressure was 198 systolic, 108 diastolic. The temperature, pulse and respirations were normal.

Examination of the blood showed a white-cell count of 12,700, with 82 per cent neutrophils. The hemoglobin was 14 gm per 100 cc. The serum bilirubin was 0.85 mg per 100 cc direct, and 1.0 mg indirect. The total protein was 5.4 gm per 100 cc, with an albumin-globulin ratio of 2.5. The chloride was 101 miliequiv per liter, and the nonprotein nitrogen 16 mg per 100 cc. A blood Hinton test was negative. The urine was normal. A stool was guaiac negative.

X-ray examination of the chest showed considerable increase in the markings throughout the lung fields, with a few nodular areas well out toward the periphery. The heart was within normal limits, and the aorta was tortuous. A plain abdominal film showed multiple dilated loops of small bowel and a large amount of gas and fluid in the cecum, ascending and transverse colon. A barium enema showed barium passing readily into the large bowel and into the region of the cecum. No defects were noted, but the preparation of the patient was not satisfactory. The barium was poorly evacuated. Multiple irregular faceted areas of calcification having the typical appearance of gallstones were found in the right upper quadrant. A Graham test showed rather poor concentration of the dye, but the gall bladder contracted fairly well after a fat-containing meal.

A Miller-Abbott tube was passed, which resulted in gradual decompression and improvement in the patient's condition. On the third hospital day a flat film showed the tip of the tube well down in the pelvis. There were still several loops of dilated small bowel. On the sixth hospital day another flat film of the abdomen showed a suggestion of a filling defect at the hepatic flexure of the colon, with dilatation of the cecum and ascending colon up to that point. A large gas bubble seemed to be in or near the gall bladder.

On the twelfth hospital day another barium enema was administered. The barium met a complete obstruction in the ascending colon close to the hepatic flexure. Fluoroscopically it was thought that the upper margin of the obstruction was shelf-like, but not enough barium passed the point to be certain of the type of lesion.

An intravenous pyelogram performed on the thirteenth hospital day revealed normally functioning kidneys and a soft-tissue pelvic mass, which appeared to be somewhat lobulated and compressed the bladder.

On the fourteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR LAMAR SOUTTER. This woman came in with a story that sounds like intestinal obstruction. At the time of her operation, twelve days after entry, x-ray studies were again indicative of obstruction. Let us look first at the x-ray films.

DR RICHARD SCHATZKI. Unfortunately the first film of the chest and the films of the first barium enema are not available. I was told by the man who examined the patient at the time of the first barium enema that the examination was unsatisfactory owing to a large amount of fecal material.

These are the two flat films with the Miller-Abbott tube in place, the retained barium is mainly

in the transverse colon, the region of the ascending colon being filled with air. The Miller-Abbott tube had passed through the small intestine and is apparently just trying to negotiate the ileocecal valve, possibly it has already passed through the valve. This is the film taken at the time of the second barium enema, and you can see the obstruction just proximal to the hepatic flexure in the upper ascending colon. The obstruction is complete, no barium passes beyond the point of obstruction. Here you see the gallstones. The intravenous pyelogram may be of interest because it shows a soft-tissue mass that is pushing the bladder downward.

DR SOUTTER. When we go back over the history we find that the patient had been in good health until a year before entry, when she began to complain of mild upper abdominal discomfort coming on usually in the evening after meals. Upper abdominal discomfort, of course, does not give us much information. It is compatible with gallstones and chronic cholecystitis, which she has. On the other hand, the symptoms at that time were vague and could have been caused by many things. Can the entire story be explained on the basis of an inflamed gall bladder that was obstructing the ascending colon and the small bowel? In the first place, the acute onset of her disease, ten days before entry, does not lead one to believe that it was due to gall bladder trouble. There was not the typical pain with radiation to the back. She had profuse watery stools and a lot of vomiting, but little evidence of inflammation. She had only a slightly elevated white-cell count, and there was no fever, no tenderness, and no mass. Furthermore, the Graham test done a few days after entry showed that the gall bladder did not fill well, which is compatible with chronic cholecystitis and cholelithiasis, but it emptied well, which is incompatible with an acutely inflamed gall bladder. Therefore, we can say that at the time she came in the symptoms were probably not related to the gall bladder.

Could she have an intrinsic lesion in the colon that was causing obstruction but was relieved only to recur again in the hospital? She had no anemia. The serum protein was slightly depleted, with a normal albumin-globulin ratio, but the protein can be depleted in a person who has been vomiting for ten days and who has had profuse watery stools. The watery stools suggest that, if she had obstruction, it was not complete. Subacute obstruction will often give diarrhea. It is therefore possible that she came in with a lesion of the ascending colon at the hepatic flexure or just below it that was causing obstruction, which was relieved during the stay in the hospital. Why did that not show up at the time of the first barium enema? As Dr Schatzki has told us, this was an unsatisfactory procedure, owing to a lot of gas and feces, and the growth that could have caused temporary obstruction would not necessarily have been visualized at that time.

Why did the bowel not empty promptly after the barium enema? That is readily explained on the basis of irritation to the bowel from previous obstruction, so that at the time of entry she had ileus, paralytic in nature, secondary to obstruction. In other words, although the obstruction was temporarily relieved, as shown by the fact that the barium passed into the cecum at the time of the first barium enema, the bowel did not empty because it had not regained its tone.

Could she have had an extrinsic inflammatory lesion that subsequently obstructed the bowel? There again the hospital course is against it. It is possible that she had an acute cholecystitis following the cholecystogram. Occasionally an acute gall bladder becomes adherent to the omentum and so forth and obstructs the colon because of inflammatory adhesions. We do not know enough about the hospital course to say whether an inflammatory process was going on. It is not suggestive, however, and I shall therefore presume that it did not occur. We have no lead that she had difficulty with the right kidney. Since she had a normal pyelogram, it is likely that no renal tumor was pressing on the colon. The history is not particularly suggestive of an ulcer of the duodenum that had perforated, thus producing this obstruction.

Could she have had a lesion a little higher up in the intestines? If she had an obstruction before entry, which is probable, it could well have been a small-bowel obstruction that was not complete. What could have given a partial obstruction in the small bowel that was later relieved? This could have been caused by some growth at the ileocecal valve, probably one that projected or pressed into the lumen of the bowel and produced partial obstruction, with subsequent relief when it came out of the lumen. Along that line we think of such things as adenoma, leiomyoma, lipoma and so forth. There could well have been a certain amount of gas and feces in the cecum from paralytic ileus if the obstruction was above this level. We do not know why the second barium enema was given. It was apparently done because the patient again had obstructive symptoms. The fact that the barium failed to pass beyond the hepatic flexure, with a *flex* of barium projecting out there, is suggestive that this was due to a growth at that level with complete obstruction, but she could also have had a growth at the ileocecal valve with intussusception up to the level of the hepatic flexure, so that the barium failed to go farther. Against intussusception is the fact that the stool was guaiac negative. Intussusception, however, is fairly rare in adults, particularly women, and it is nearly always associated with blood in the stool. We do not know whether she had blood in the stool at the time of the second enema, but she could perfectly well have had a small-bowel lesion that had intussuscepted

into the colon because it lay close to the ileocecal valve.

The intravenous pyelogram is interesting. The most frequent cause of a fairly well outlined pelvic mass pressing into the bladder in a woman who has passed the menopause with no particular story of pelvic difficulty is a fibroid uterus. It is difficult to visualize any obstructive lesion of the descending colon that would interfere with the bladder without there being a definite palpable mass. Furthermore, without signs of obstruction at that level at the time of the two barium enemas, the lesion appears to have been higher. Further suggestive evidence of a lesion in the small bowel, rather than one in the large bowel, is the fact that the vomiting came on almost immediately. With a polypoid type of growth obstructing the small bowel, one would expect vomiting earlier than if she had had obstruction at the hepatic flexure.

In conclusion I shall say that this woman's lesion was neoplastic, that it was probably benign, because of the blood picture and history, that she had temporary obstruction prior to coming in, which was relieved on entry, that the lesion was probably in the region of the ileocecal valve and that she had intussusception at the time that the second barium enema was taken. It is, of course, impossible to exclude a neoplastic lesion at or just below the hepatic flexure.

DR. SCHATZKI: Against intussusception is perhaps the fact that in the film you can see air in what appears to be a normal cecum.

CLINICAL DIAGNOSES

Cholelithiasis?
Carcinoma of large bowel

DR. SOUTTER'S DIAGNOSIS

Benign tumor of ileocecal valve, with intussusception of ileum into cecum and ascending colon

ANATOMICAL DIAGNOSIS

Adenocarcinoma of ascending colon

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: This patient was operated on by Dr. Langdon Parsons. I am sorry that he is not here to describe the operative findings. He found a tumor in the ascending colon, and resected it, together with a small portion of the terminal ileum. The specimen that we received showed a carcinoma of the ascending colon at about its mid-portion, it was 5 or 6 cm. from the ileocecal valve and 13 cm. from the edge of the resection. There were a few enlarged lymph nodes in the attached mesentery, but these were histologically free from metastases. If an intussusception had been present, there was no trace of it at the time of operation.

X-ray examination of the chest showed considerable increase in the markings throughout the lung fields, with a few nodular areas well out toward the periphery. The heart was within normal limits, and the aorta was tortuous. A plain abdominal film showed multiple dilated loops of small bowel and a large amount of gas and fluid in the cecum, ascending and transverse colon. A barium enema showed barium passing readily into the large bowel and into the region of the cecum. No defects were noted, but the preparation of the patient was not satisfactory. The barium was poorly evacuated. Multiple irregular faceted areas of calcification having the typical appearance of gallstones were found in the right upper quadrant. A Graham test showed rather poor concentration of the dye, but the gall bladder contracted fairly well after a fat-containing meal.

A Miller-Abbott tube was passed, which resulted in gradual decompression and improvement in the patient's condition. On the third hospital day a flat film showed the tip of the tube well down in the pelvis. There were still several loops of dilated small bowel. On the sixth hospital day another flat film of the abdomen showed a suggestion of a filling defect at the hepatic flexure of the colon, with dilatation of the cecum and ascending colon up to that point. A large gas bubble seemed to be in or near the gall bladder.

On the twelfth hospital day another barium enema was administered. The barium met a complete obstruction in the ascending colon close to the hepatic flexure. Fluoroscopically it was thought that the upper margin of the obstruction was shelf-like, but not enough barium passed the point to be certain of the type of lesion.

An intravenous pyelogram performed on the thirteenth hospital day revealed normally functioning kidneys and a soft-tissue pelvic mass, which appeared to be somewhat lobulated and compressed the bladder.

On the fourteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR LAMAR SOUTTER. This woman came in with a story that sounds like intestinal obstruction. At the time of her operation, twelve days after entry, x-ray studies were again indicative of obstruction. Let us look first at the x-ray films.

DR RICHARD SCHATZKI. Unfortunately the first film of the chest and the films of the first barium enema are not available. I was told by the man who examined the patient at the time of the first barium enema that the examination was unsatisfactory owing to a large amount of fecal material.

These are the two flat films with the Miller-Abbott tube in place, the retained barium is mainly

in the transverse colon, the region of the ascending colon being filled with air. The Miller-Abbott tube had passed through the small intestine and is apparently just trying to negotiate the ileocecal valve, possibly it has already passed through the valve. This is the film taken at the time of the second barium enema, and you can see the obstruction just proximal to the hepatic flexure in the upper ascending colon. The obstruction is complete, no barium passes beyond the point of obstruction. Here you see the gallstones. The intravenous pyelogram may be of interest because it shows a soft-tissue mass that is pushing the bladder downward.

DR SOUTTER. When we go back over the history we find that the patient had been in good health until a year before entry, when she began to complain of mild upper abdominal discomfort coming on usually in the evening after meals. Upper abdominal discomfort, of course, does not give us much information. It is compatible with gallstones and chronic cholecystitis, which she has. On the other hand, the symptoms at that time were vague and could have been caused by many things. Can the entire story be explained on the basis of an inflamed gall bladder that was obstructing the ascending colon and the small bowel? In the first place, the acute onset of her disease, ten days before entry, does not lead one to believe that it was due to gall bladder trouble. There was not the typical pain with radiation to the back. She had profuse watery stools and a lot of vomiting, but little evidence of inflammation. She had only a slightly elevated white-cell count, and there was no fever, no tenderness, and no mass. Furthermore, the Graham test done a few days after entry showed that the gall bladder did not fill well, which is compatible with chronic cholecystitis and cholelithiasis, but it emptied well, which is incompatible with an acutely inflamed gall bladder. Therefore, we can say that at the time she came in the symptoms were probably not related to the gall bladder.

Could she have an intrinsic lesion in the colon that was causing obstruction but was relieved only to recur again in the hospital? She had no anemia. The serum protein was slightly depleted, with a normal albumin-globulin ratio, but the protein can be depleted in a person who has been vomiting for ten days and who has had profuse watery stools. The watery stools suggest that, if she had obstruction, it was not complete. Subacute obstruction will often give diarrhea. It is therefore possible that she came in with a lesion of the ascending colon at the hepatic flexure or just below it that was causing obstruction, which was relieved during the stay in the hospital. Why did that not show up at the time of the first barium enema? As Dr Schatzki has told us, this was an unsatisfactory procedure, owing to a lot of gas and feces, and the growth that could have caused temporary obstruction would not necessarily have been visualized at that time.

staphylococcal infections in human beings in which relapses have occurred because of localized infections, penicillin therapy has often been continued for long periods without the development of any measurable degree of penicillin resistance. Although it is too soon to draw any conclusions on this point, the evidence so far available suggests that, except for staphylococcal infections, penicillin resistance will probably not be of any great clinical importance.

The absorption and excretion of penicillin and its diffusion into various body fluids are the next important features to be considered. After intramuscular injections, absorption of penicillin is rapid, the maximum level being achieved within fifteen to twenty minutes. Thus, it is entirely unnecessary and superfluous to begin

therapy with a single intravenous dose, as many physicians are inclined to do. After the drug is absorbed, it is rapidly eliminated, so that 80 per cent of the intramuscular dose appears in the urine within the first two hours, and less than 5 per cent remains after four hours. The rapid absorption and rapid elimination of penicillin are therefore responsible for the greatest disadvantage of penicillin therapy at present, namely, the necessity for frequent parenteral injections. Of the many methods used in attempts to delay absorption, Rammelkamp and Kirby consider the intramuscular injection of penicillin in beeswax-peanut oil mixtures to be the most promising. Effective blood levels can be maintained for as long as twenty-four hours after 300,000 units of penicillin given in 1 cc. of such a mixture.

Concerning oral preparations, these authors consider that none of the enteric coatings, oils or acids thus far employed give better results than those obtained with the ingestion of penicillin dissolved in tap water. With any of these preparations,

five or six times as much penicillin must be administered to produce levels equivalent to those obtained following parenteral injections. It is worth mentioning that even this ratio is valid only when the penicillin is given before meals, since in most persons little or no penicillin is absorbed if it is given orally within a short time after the ingestion of food.

The diffusion of penicillin into body fluids and cavities occurs irregularly and generally only to a small extent. For this reason, local therapy as well as parenteral treatment is usually necessary in the treatment of infections of the pleura, pericardium and joints. In some localized infections, such as well established empyemas, parenteral injections are unnecessary, favorable results often being obtained by local injections alone. In meningitis, al-

though there are reports of a few patients who have been cured by parenteral penicillin alone, clinical experience has shown that others have failed to respond to such treatment. In some cases, moreover, bacterial meningitis has actually appeared during parenteral treatment of extrameningeal infections. Penicillin should therefore be given both parenterally and intrathecally in cases of meningitis. There are two notable exceptions. In cases of syphilitic meningitis, excellent results have been obtained with intramuscular penicillin, and in cases of meningococcal infections, systemic sulfonamide therapy is usually adequate and probably more effective than treatment with penicillin given both intrathecally and parenterally.

In certain conditions, notably subacute bacterial endocarditis, various forms of late syphilis and chronic osteomyelitis, the factor of penetration is extremely important. Favorable results can be obtained and relapses avoided only by the maintenance of high blood levels continuously for long periods.

DOSAGE OF PENICILLIN

THERE is considerable confusion in the minds of most physicians about the dosage of penicillin in the treatment of various infections. This is due in part to the fact that the early studies on penicillin therapy were made when the material was quite scarce, as a result of which attempts were made to define the dose in terms approximating the minimum effective amount. When the supply of the antibiotic became more plentiful, the trend was in the opposite direction, large doses being advocated and used empirically. Some justification for the large doses was found in the better results achieved in such conditions as subacute bacterial endocarditis and other infections in which small doses had failed to produce a satisfactory clinical response. A

knowledge of the factors determining the optimum dose to be used in any given set of circumstances, however, is essential if one is to provide adequate therapy and at the same time to avoid ridiculous waste of large amounts of this valuable material.

The factors determining the dosage of penicillin in infections have been recently reviewed by Rammelkamp and Kirby*. These authors point out that there is a closer correlation with penicillin than with sulfonamides between the sensitivity of bacteria in vitro and the clinical results obtained. This is attributed in part to the fact that sulfonamides are inhibited by substances contained in pus and exudates, whereas the same is not true of penicillin. Penicillin is selective in its activity. For the most part, this selectivity refers to the high degree of antibacterial action of penicillin against gram-positive bacteria and its failure to inhibit the growth of most gram-negative bacteria. There is considerable variation, however, in the degree of sensitivity of different bacteria and even of different strains of the same organism. For practical purposes, however, most of penicillin-sensitive bacteria that are frequently encountered, particularly the gonococcus, pneumococcus and beta-hemolytic streptococcus, exhibit variations that are not of sufficient clinical significance to affect the results of therapy. In cases of subacute bacterial endocarditis and in certain staphylococcal infections, on the other hand, there may be wide variations in the sensitivity of the etiologic organisms. It is only in the latter types of cases, therefore, that a knowledge of the sensitivity of the organism may be of importance both from the standpoint of therapy and that of prognosis.

The problem of acquired resistance or fastness of bacteria has received intensive study because of the importance of that feature in relation to sulfonamide therapy. It has been shown that most of the penicillin-susceptible organisms develop resistance only after prolonged exposure to the antibiotic. Clinical experience has indicated that, with the exception of the staphylococcus, well substantiated instances of penicillin resistance acquired during therapy have been rare. Furthermore, in certain cases of streptococcal, pneumococcal and

though there are reports of a few patients who have been cured by parenteral penicillin alone, clinical experience has shown that others have failed to respond to such treatment. In some cases, moreover, bacterial meningitis has actually appeared during parenteral treatment of extrameningeal infections. Penicillin should therefore be given both parenterally and intrathecally in cases of meningitis. There are two notable exceptions. In cases of syphilitic meningitis, excellent results have been obtained with intramuscular penicillin, and in cases of meningococcal infections, systemic sulfonamide therapy is usually adequate and probably more effective than treatment with penicillin given both intrathecally and parenterally.

In certain conditions, notably subacute bacterial endocarditis, various forms of late syphilis and chronic osteomyelitis, the factor of penetration is extremely important. Favorable results can be obtained and relapses avoided only by the maintenance of high blood levels continuously for long periods.

Rammelkamp and Kirby also emphasize the fact that, although penicillin is highly effective against the organisms present in the throat in patients with tonsillitis and pharyngitis, lasting beneficial effects are exerted only when penicillin is given parenterally. Local therapy with gargles or sprays is ineffective. After intramuscular injections, however, streptococci disappear or rapidly diminish, but they reappear if treatment is discontinued too soon. It has been definitely demonstrated that, in order to obtain a permanent cure in cases of streptococcal sore throat, it is necessary to continue treatment for five or more days. In pneumococcal pneumonia, too, it is necessary to continue treatment for several days after apparent recovery to ensure sterilization of the infected tissues and to prevent relapse. It is possible that final recovery is brought about in these cases and in certain other infections with the help of the body's own defense mechanisms.

The frequency with which doses are given depends, of course, on the time during which effective levels must be maintained. Rammelkamp and Kirby present evidence that indicates that some antibacterial effect persists after the time when penicillin is no longer demonstrable in the serum by the usual tests. Doubling the size of the dose produces a blood level that is twice as high, but the effective level is prolonged by only one third. The high levels that result from the use of extremely large doses are usually well in excess of those necessary to exert the maximal antibacterial effect. Injections of 20,000 units produce levels in the blood that are considered to be maximum against the staphylococcus for less than one hour, although definite bacteriostasis probably persists for another two hours. For the hemolytic streptococcus, on the other hand, the same dose produces concentrations that have maximum antibacterial action for more than two and a half hours and partial inhibitory levels for another one and a half to two hours. Other factors of importance in determining the size of the dose of penicillin are the severity of the infection, the vascularity of the areas involved and the barriers through which penicillin must diffuse or penetrate to come in contact with the infecting organism.

On the basis of all these factors it is possible to plan rational schemes of treatment. In staphylococcal infections, for example, 25,000 units every two hours will provide optimal levels continuously in the blood stream, for streptococcal infections, 15,000 units every three hours are adequate for this purpose. Two points are especially emphasized. One is that doses producing optimal concentrations of penicillin in the blood stream are all that are necessary. Although larger doses raise the concentration of penicillin, they do not increase the already maximum antibacterial activity and are therefore wasteful. The other point is that, for all practical purposes, penicillin remains active in the tissues for only three, or at most four, hours after the usual therapeutic dose. The use of penicillin at intervals longer than four hours is therefore potentially dangerous, even though occasional infections due to highly sensitive bacteria may respond favorably to doses given at wider intervals.

EFFECT OF VITAMIN SUPPLEMENTS

Our British cousins, a little less enthusiastic than ourselves, who are a mixture of various races although speaking a similar tongue, seem inclined to take their vitamins with a grain of salt. It is not that they are any less serious about them, it is rather that, conservatively, they seem to prefer them from an apothecary's shop than a slot machine and are even inclined to doubt that health improves in direct proportion to the amount of vitamin concentrate assimilated.

As recently as February, 1946, Bransby, Burns, Magee and MacKecknie* published the results of a study on the effect of a daily vitamin supplement on the health and development of children. The test was made on 1620 children, aged five to fourteen years, attending day schools in the towns of Stoke-on-Trent and Salford. The subjects were divided into the conventional two groups at random, one of which received a daily placebo and the other a capsule containing 4000 int units of vitamin A, 1 mg of vitamin B₁, 2 mg of riboflavin, 20 mg of nicotinamide, 50 mg of ascorbic acid and 600 int units of

*Bransby, E. R., Burns, J. L., Magee, H. E., and MacKecknie, D. M. Effect of daily vitamin supplement on health and development of children. *Brit M J* 1 193 197 1946

vitamin D. The tests, which ran for a year, were similar in the two towns but not identical. In Stoke medical, dental and anthropometric data were collected three times during the year, and in Salford twice, in Salford facts were gathered on the economic condition of the subjects, in Stoke dynamometer and hanging-bar tests were performed, and in Salford hearing was tested by means of the audiometer.

The results were essentially nil—a temporary disappointment, no doubt, to the vitamin enthusiasts and faddists: the vitamin supplement had no apparent consistent effect “on growth, strength, endurance, fatigue potential, incidence or severity of clinical conditions, hearing and absenteeism from school. The vitamin supplement had a beneficial effect on gingivitis in Stoke but not in Salford.”

These British experiments, it is true, did not elaborate on all the developmental, nutritional and clinical factors that could have been affected by vitamin therapy, nor did they attempt to measure the incalculable *jose de viere* that might have resulted from such regular indulgence in these encapsulated cocktails, or to initiate any manner of “shock therapy” by the use of massive doses, such as has been done effectively for certain particular purposes. On the basis of their findings, however, the authors suggest that the recommended vitamin requirements of the National Research Council of the United States are too high, with particular reference to ascorbic acid, that the amounts contained in the average diet are sufficient for the maintenance of satisfactory health and that, consequently, the need for supplemental rations has been exaggerated. These results, however, are only suggestive. We must continue to remember that there is a great deal more to normal nutrition than an adequate vitamin intake and that, contrary to a growing popular belief, supplementary vitamins do not constitute a complete, concentrated diet.

MASSACHUSETTS MEDICAL SOCIETY

EXECUTIVE COMMITTEE OF THE COUNCIL

On April 24, 1946, the Executive Committee of the Council, on the recommendation of the Committee on Membership and representatives from the supervising centers, took the following actions:

Allowed the following named fellows, applying for retirement and with all dues paid and in good standing, to retire under the provisions of Chapter I, Section 5, of the by-laws:

Bartlett, William B. (Middlesex South), 28 Monument Street, Concord
Beals, Lester H. (Franklin), 701 Plymouth Road, Claremont, California
Bigelow, Enos H. (Middlesex South), 65 Edgell Road, Framingham Centre
Boutwell, Horace K. (Norfolk), 15 Green Street, Brookline
Bremer, J. L. (Suffolk), 113 Marlboro Street, Boston
Canavan, Myrtelle M. (Norfolk), 2061 Dorchester Avenue, Boston
Draper, Alexis L. (Norfolk), 1107 Washington Street, Dorchester Centre
Duckering, Florence W. (Suffolk), 483 Beacon Street, Boston
Grant, Justin F. (Suffolk), 587 Tremont Street, Boston
Higgins, George V. (Norfolk South), Corner Main and Warren streets, Randolph
Hollister, F. M. (Plymouth), South Duxbury
Holt, William L. (Hampshire), Amherst
Merritt, S. Virgil (Bristol South), 297 Osborn Street, Fall River
Page, Calvin G. (Suffolk), 128 Marlboro Street, Boston
Phelps, John S. (Essex South), 768 Boston Street, Lynn
Schirmer, J. Walter (Suffolk), 85 Lawton Road, Needham
Tilden, Irving N. (Bristol South), Mattapoisett
Tyler, Winsor M. (Middlesex South), 1482 Commonwealth Avenue, Brighton

Allowed the following named fellow, applying for retirement but who is in arrears of dues for the year 1945, to have his dues for the year 1945 to the Massachusetts Medical Society remitted under the provisions of the by-laws, Chapter I, Section 6, and then to retire under the provisions of Chapter I, Section 5, of the by-laws:

Walsh, John E. (Suffolk), 238 Beach Street, Revere

Allowed the following named fellows, applying for resignation with all dues paid and in good standing, to resign under the provisions of Chapter I, Section 7, of the by-laws:

Adler, Alexandra (Suffolk), Duke University, Durham, North Carolina
Finnegan, William F. (Non-Resident), 380 North Eighth Street, Lebanon, Pennsylvania
Haskell, C. D. (Non-Resident), 141 S. Meridian Street, Indianapolis, Indiana
Hyde, Fritz C. (Non-Resident), 320 East 72nd Street, New York City
Joy, Genevieve L. (Non-Resident), 202 South Palouse Street, Walla Walla, Washington
Leone, Joseph P. (Norfolk South), Quincy City Hospital, Quincy
McMackin, John V. (Non-Resident), 406 Huntington Building, Miami, Florida
Redlich, Frederick C. (Non-Resident), 333 Cedar Street, New Haven, Connecticut
Staples, O. Sherwin (Norfolk), Hitchcock Clinic, Hanover, New Hampshire
Yahn, George W., III (Suffolk), P. O. Box 38, Camarillo, California

Allowed the following named fellows, applying for resignation from the Massachusetts Medical Society but who are in arrears of dues, to have these dues owed the Massachusetts Medical Society remitted under Chapter I, Section 6, of the by-laws and then to resign from the Massachusetts Medical Society under the provisions of Chapter I, Section 7, of the by-laws:

Forster, Francis M. (Norfolk), 1025 Walnut Street, Philadelphia, Pennsylvania
Ruesch, Jurgen (Middlesex South), University of California Medical School, The Medical Center, San Francisco, California

Allowed the following named fellows to change their membership from one district society to another, without change of legal residence, under the provisions of Chapter III, Section 3, of the by-laws:

Bayles, Theodore B, 94 Summer Street, Weston (Middlesex South to Suffolk)
 D'Errico, Emilio, 14 Everett Avenue, Winchester (Remain in Middlesex South)
 Hanson, Wm T, 30 Bellevue Road, Stoneham (Remain in Plymouth)
 Hare, Hugh F, 66 Fountain Street, West Newton (Middlesex South to Suffolk)
 Newell, John L, 35 Walnut Place, Brookline (Norfolk to Suffolk)
 Shain, Arthur I, 63 Bay State Road, Boston (Suffolk to Norfolk)
 Thorn, George W, 983 Memorial Drive, Cambridge (Middlesex South to Suffolk)
 Warren, Richard, 30 Heath Street, Brookline (Remain in Suffolk)

had been a member of the staff of the Newton-Welles Hospital for twenty-six years. He was a fellow of the American Medical Association.
 A son, four daughters and a sister survive.

McLEOD — Melvin S. McLeod, M.D., of Melrose, died February 26. He was in his fiftieth year.
 Dr. McLeod received his degree from the University of Vermont College of Medicine in 1920.
 His widow and two sons survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

PERSONNEL NOTES

William J. Welch, M.D., has been appointed physician in-chief of the Mobile Blood Donor Unit of the Division of Biologic Laboratories, Massachusetts Department of Public Health. Dr. Welch, who served for two years in the European Theater of Operations as a captain in the Army Medical Corps, has charge of the organization and technical operation of the field team that collects the voluntary blood donations.

Donald A. Martin, M.D., has been appointed director of the Massachusetts Hospital and Health-Center Survey Program. The survey was launched by Governor Tobin for the purpose of studying existing hospital and health facilities in anticipation of passage of the Hill-Burton Bill (S 191). Prior to his appointment, Dr. Martin was acting superintendent of the Lakeville State Sanatorium in Middleboro.

Robert E. Ober, M.D., epidemiologist with the Division of Communicable Diseases, Massachusetts Department of Public Health, has returned to duty following twenty-nine months overseas service with the Mediterranean Allied Air Forces.

Robert A. MacCready, M.D., recently discharged from the Army Medical Corps, where he held the rank of major, has returned to the Massachusetts Department of Public Health as epidemiologist in the Division of Communicable Diseases. He will be in administrative charge of the Laboratory Approval Program.

Mary Carr Baker, formerly supervisor of public-health education, Massachusetts Department of Public Health, is now field program supervisor of the new Blood Program. A field representative, Mrs. Baker supervises collaborative activities between the Department, the American Red Cross and community organizations in arranging for local participation in the Blood Donor Service.

Philip W. Johnston, Ph.D., has returned to the Division of Maternal and Child Health as research consultant in Field Service in Child Growth and Development, his duties including the preparation and validation of tests of vision and hearing for school children. During the war, Dr. Johnston held the rank of lieutenant in the United States Naval Reserve. He was first attached to the Bureau of Naval Personnel as a psychologist but later spent eighteen months in the Pacific area as radar officer on the U.S.S. *Boston*.

Leon A. Alley, M.D., has returned from duty in the European Theater of Operations as a lieutenant colonel after having served five years in the Army Medical Corps. He will resume his position as superintendent of the Lakeville State Sanatorium in Middleboro.

Elizabeth E. Barry, R.N., B.N., has been appointed supervising instructor in public-health nursing (pediatrics), Bureau of Public Health Nursing for the Rheumatic Fever Program, which is soon to be established in the Massachusetts Department of Public Health. She is a graduate of Yale University School of Nursing and Massachusetts State College.

Jane Y. Harshberger, R.N., M.A., a graduate of Yale University School of Nursing and of the University of Pennsylvania, has recently joined the staff of the Bureau of Public Health Nursing as supervising instructor in public-health nursing. She is conducting an educational program in maternity nursing for public-health and hospital nurses.

Reinstated the following named physicians, who have been deprived of membership for the nonpayment of dues, provided their arrears in dues at the time of deprivation both to the Massachusetts Medical Society and to their district societies, plus current year dues both to the Massachusetts Medical Society and to their district societies be sent to the Treasurer of the Society, in accordance with Chapter I, Section 10, of the by-laws:

Bennett, Max (Bristol North), 176 County Street, Attleboro
 Gilbert, Meyer M. (Worcester), 30-A Boynton Street, Worcester
 McDonald, J. F. (Worcester North), Main Street, Ashburnham
 O'Brien, John Francis (Middlesex North), 77 Payson Road, Brookline
 Tynan, J. P. (Suffolk), 801 Broadway, South Boston

Allowed the following named fellows, who have been ill for a number of years and totally disabled or who have been totally disabled through military service, to have their dues to the Massachusetts Medical Society remitted in the future as long as they are permanently disabled and unable to carry on medical practice and duties under the provisions of Chapter I, Section 6, of the by-laws:

Champ, Anthony M. (Plymouth), 109 Manomet Street, Brockton
 Hendry, John J. (Suffolk), 681 Mountain Avenue, Revere
 Krieger, William L. (Norfolk South), 15 Lincoln Avenue, Wollaston
 Sawyer, Alpha R. (Norfolk), 79 Poplar Street, Roslindale
 Sweeney, William J. (Middlesex East), 4 Avon Street, Wakefield

Allowed the following named fellow, who was deprived of membership in the Massachusetts Medical Society in 1942 on recommendation of the Committee on Membership to the Executive Committee, to be restored to active membership in good standing under the provisions of Chapter I, Section 10 of the by-laws. Former deprivation of fellowship was recommended because of nonpayment of dues. No information was obtained that he was in active military service:

Quigley, Thomas J. (Suffolk), 1633 Tremont Street, Boston

The personnel of the Committee on Membership is as follows: Harlan F. Newton, *chairman*, Roy V. Baketel, William A. R. Chapin, Peirce H. Leavitt, and Samuel N. Vose. The representatives of the supervising censors were as follows: William H. Allen, H. Quimby Gallupe, and Albert E. Parkhurst.

MICHAEL A. TIGHE, M.D., *Secretary*
 Executive Committee

DEATHS

JACK — Lewis H. Jack, M.D., of West Newton, died May 3. He was in his seventy-fourth year.

Dr. Jack received his degree from Harvard Medical School in 1899. At various times during his medical career he was associated with the Boston City, Boston Lying-in, Long Island, Waltham, Winchester and Cambridge hospitals. He

MISCELLANY

DEDICATION AT McLEAN HOSPITAL

On May 17, the Scientific Research Laboratory of the McLean Hospital at Waverley, a unit of the Massachusetts General Hospital, was dedicated. The morning program included talks by Dr C K Drinker and Dr Jordi Folch. Following luncheon and inspection of the laboratory, addresses were given by Dr Stanley Cobb, Dr Herbert S Gasser, of New York City, and Dr Wilder Penfield, of Montreal. At the reception and dinner, held at the Harvard Club that evening, Dr E A Strecker, of Philadelphia, was the principal speaker.

BOOKS—WAR VICTIMS

During the war, the libraries of half the world were destroyed in the fires of battle and in the fires of hate and fanaticism. Where they were spared physical damage, they were impoverished by isolation. There is an urgent need—now—for the printed materials that are basic to the reconstruction of devastated areas and that can help to remove the intellectual blackout of Europe and the Orient.

There is need for a pooling of resources and for co-ordinated action in order that the devastated libraries of the world may be restocked, so far as possible, with needed American publications. The American Book Center for War Devastated Libraries, Incorporated, has come into being to meet this need. It is a program that is born of the combined interests of library and educational organizations, of governmental agencies and of many other official and nonofficial bodies in the United States.

The American Book Center is collecting and is shipping abroad scholarly books and periodicals that will be useful in research and necessary in the physical, economic, social and industrial rehabilitation and reconstruction of Europe and the Far East.

The Center cannot purchase books and periodicals, it must depend on gifts from individuals, institutions and organizations. Each state will be organized to participate in the program through the leadership of a state chairman. Other chairmen will organize interest in the principal subject fields.

Co-operation with these leaders or direct individual contributions are welcomed.

What is needed—Shipping facilities are precious and demand that all materials be carefully selected. Emphasis is placed on publications issued during the past decade, on scholarly books that are important contributions to their fields, on periodicals (even incomplete volumes) of significance and on fiction and nonfiction of distinction. All subjects—history, the social sciences, music, fine arts, literature and especially the sciences and technologies—are wanted.

What is not needed—Textbooks, out-dated monographs, recreational reading, books for children and young people, light fiction, materials of purely local interest, popular magazines, such as *Time*, *Life*, *National Geographic* and so forth, and popular nonfiction of little enduring significance, such as Gunther's *Inside Europe*, Haliburton's *Royal Road to Romance* and so forth, should not be sent. Only carefully selected federal and local documents are needed, and donors are requested to write directly to the Center with regard to specific documents.

How to ship—All shipments should be sent prepaid via the cheapest means of transportation to The American Book Center, c/o The Library of Congress, Washington 25, D C. Although the Center hopes that donors will assume the costs of transportation of their materials to Washington, when this is not possible, reimbursements will be made on notification by card or letter of the amount due. The Center cannot accept material that is sent collect. Reimbursement cannot be made for packing or other charges beyond actual transportation. When possible, periodicals should be tied together by volume. It will be helpful if missing issues are noted on incomplete volumes.

CORRESPONDENCE

SCARLET FEVER OR STREPTOCOCCAL INFECTION?

To the Editor: Sing a dirge for scarlet fever—it will soon be as extinct (statistically) as the Dodo bird and the heath hen!

To be sure the quarantine period for the disease has been cut from six to three weeks in most places, but this three weeks out of a family's life, when a case of "streptococcus throat" (caused by the same strain of the same "bug") is not quarantined at all, is a useless sacrifice so far as controlling the spread of the disease is concerned. So why quarantine?

Despite the fact that recent advances have proved that we can, with the first few injections of penicillin, render the throat free from streptococci and practically prevent complications, the Blue Cross will only pay for hospitalization of its policyholders when they have complications! It will, however, pay without question for hospitalization of "hemolytic streptococcus throats with a toxic rash" (If there is one disease in which hospitalization is advisable to save life and prevent permanent crippling, it is scarlet fever—all patients should be able to get injections of penicillin every three hours for at least six days.)

Henceforth, I see no cases of scarlet fever. All my patients will have streptococcus throats with toxic rashes. No more quarantine penalties, no more "gypping" by the Blue Cross of my patients! How about yours? Statuistics will prove, I am sure, that in a few years there is no such thing as scarlet fever!

It is another version of the old story of diphtheria. With the advent of antitoxin in England, antivivisectionists pointed out, quite correctly, that there was a sharp increase in the number of cases of diphtheria. They failed to mention, however, that there were no cases of laryngeal croup. The profession had been educated to call diphtheria "diphtheria." Why not let us call streptococcal infections "streptococcal infections"?

REPORT OF MEETING

MEDICAL LIBRARY ASSOCIATION

The Medical Library Association held its forty-fifth annual meeting in New Haven, Connecticut, on March 25, 26 and 27. Headquarters were at the Hotel Taft and sessions met in the Historical Library, Sterling Hall of Medicine, Yale University. The program featured reports on the Army Medical Library, a symposium entitled "International Co-operation" and addresses on the subjects "Training for Medical Librarianship" and "British Medical Libraries in Wartime."

The following officers were elected: president, Dr Walton B McDaniel, 2d, of the College of Physicians, Philadelphia, vice-president, Dr C Abbott Beling, of Newark, New Jersey, secretary, Miss Heath Babcock, of the New York State Medical Library, Albany, New York, and treasurer, Mr Jurgen G Raymond, of the New York Academy of Medicine, New York City.

It was voted to hold the 1947 convention in Cleveland, Ohio, the exact date to be determined later.

EASTERN ASSOCIATION OF ELECTROENCEPHALOGRAPHERS

The second regular meeting of the Eastern Association of Electroencephalographers was held on Friday, April 12, at the Postgraduate Club of the Institute of Living at Hartford, Connecticut, with thirty-six members present. A constitution and by-laws were adopted, creating a new office of vice-chairman, to which post Dr Herbert H. Jasper, of the Neurological Institute of Montreal, was elected.

As chairman of the Liaison Committee, Dr Hallowell Davis reported that the American Physiological Society had appointed Dr Herbert H. Jasper and Dr Frederick A. Gihhs to represent their society on the joint committee to review the problems of clinical electroencephalography and to consider appropriate action to promote a high standard of electroencephalography. The Council on Physical Medicine of the American Medical Association has also replied favorably to the memorandum of the Eastern Association of Electroencephalographers, with the American Neurological Association and the American Psychiatric Association both informally expressing favorable interest.

Dr Milton H. Kihhe, of Springfield, Massachusetts, presented a paper describing experiences and findings in electroencephalography in an Army general hospital, with Dr Charles E. Henry following with a corresponding paper based on Navy experience.

At the meeting on Friday, March 1, at the Institute of Living at Hartford, Connecticut, when the Eastern Association of Electroencephalographers was organized, Dr Robert S. Schwab was elected chairman and Dr Charles W. Stephenson was elected recorder.

NOTICES

ANNOUNCEMENTS

Dr Louis Hermanson announces the removal of his office to 171 Bay State Road, Boston.

Dr John A. Murphy announces the opening of an office at 47 Bay State Road, Boston, for the practice of gynecology and obstetrics.

Dr Frederick P. Nadel, on termination of military service, is resuming the practice of medicine and surgery at 269 Harvard Street, Cambridge 39.

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, June 6, at 7 15 p.m., in the classroom of the Nurses' Residence. Dr Edwin B. Astwood will speak on the subject "Thiouracil in the Treatment of Hyperthyroidism." Dr Merry Pittman will be chairman.

GRANTS AND FELLOWSHIPS IN CANCER RESEARCH

The Committee on Growth of the National Research Council, acting for the American Cancer Society, announces that it will entertain applications for grants in cancer research to become effective July 1, 1947. Applications will be received until September 15, 1946. Applications for fellowships and senior fellowships in cancer research of the American Cancer Society for the ensuing year will be received until December 1, 1946.

To date the Committee on Growth has recommended to the American Cancer Society a total of seventy-five research grants and fourteen fellowships. The committee will continue to recommend support of research in the basic sciences

and in clinical investigative medicine broadly pertaining to problems of growth. It will also continue to rely heavily for counsel on its advisory divisions of chemistry, biology, physics and clinical investigation and their subjacent panels in specialized areas of research.

Applications for research grants for the current year will no longer be entertained. Communications should be addressed to the Committee on Growth, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D. C.

NEW ENGLAND HEART ASSOCIATION

The annual meeting of the New England Heart Association will be held on Monday, June 3, in the Dowling Amphitheater of the Boston City Hospital at 8 15 p.m. The scientific program will be preceded by a short business meeting, including the election of officers for the ensuing year.

PROGRAM

Indications for Removal of Foreign Bodies from the Heart, and the Technic of Cardiomy Dr Dwight E. Harken

Electrocardiographic Variations in Heart Trauma Dr Paul Zoll

Discussion

Interested physicians and medical students are invited to attend.

ETHER INHALERS IN EARLY USE

WILLIAM W FORD, M.D.*

BALTIMORE, MARYLAND

ON A brick building at 17-19 Tremont Street, Boston, an inconspicuous bronze tablet commemorates the first of two events that served to introduce ether anesthesia and thereby changed the history of surgery. The tablet is inscribed as follows "On Sept 30, 1846, in a room in this building, Dr William Thomas Green Morton first demonstrated the value of ether as an anaesthetic in a dental operation." A little more than two weeks from this date, on October 16, 1846, Morton, a successful dentist of twenty-seven who was also an enrolled student of medicine at Harvard, gave his epochal demonstration of ether as a pain-relieving agent in an operation for a vascular tumor of the neck, performed by Dr John Collins Warren.

Following this discovery ether inhalers were produced in great variety and number. They included intricate and costly pieces of machinery, as well as mere bladders equipped with an inhaling tube and mouthpiece. The earliest of these inhalers, after Morton's, were brought out in this country, although Morton's instrument remained the only one in general use here. Many of the earliest, if not the most elaborate, ether inhalers in Europe were those produced in England, where the foundations of our modern scientific knowledge of anesthesia were laid through the work of John Snow.

In the dental operation of September 30, 1846, Morton administered ether by means of a saturated handkerchief given to the patient, Eben H Frost, to inhale when he asked to be mesmerized before the extraction of an ulcerated tooth. During the interval, however, between this highly successful experiment and the operation at the hospital, Morton having applied to Dr Warren on October 5 for permission to demonstrate his compound, a search was made for a suitable inhaling apparatus. Morton apparently had previously been interested in methods of inhaling, this interest, according to his own statements, dating back to the summer of 1844. At that time, when he was a medical student under Dr Charles T Jackson prior to his admission to Harvard, and as a result of Jackson's suggesting

ether when he was filling a tooth for a patient, he pored over the ether literature he found in Jackson's library and began his self-experiments with the drug, hoping to prove it an alleviator of pain in dentistry.

Aside from Pereira's *Materia Medica*, there are no specific references concerning Morton's reading at this period, but he might easily have come across such references to ether inhalation as those of Richard Pearson, Thornton and Nyvsten among others. During the 1830's and early 1840's, moreover, there was a good deal published, including the writings of Scudamore and Corrigan, on the inhalation treatment of diseases of the respiratory tract. Frequently there was some mention, if not a description, of apparatus for the inhalation of iodine, chlorine and other vapors. Above all, any early ideas he may have entertained on the subject of anesthesia in dentistry were greatly strengthened in January, 1845, by his witnessing the demonstration (technically a failure) of nitrous oxide gas by Horace Wells, his former dental instructor and partner.

Late in the summer of 1846, after various experiments, which Morton claimed included some on his dental assistants as well as on animals, had failed to produce any conclusive results and he was "much discouraged," he determined to procure a satisfactory form of apparatus. To this end he had several conferences with Joseph Wightman, maker of philosophical instruments on Cornhill. Morton¹ stated

While examining his bags for inhaling nitrous oxide gas, the thought struck me that I could put the ether into one of these, and by making an opening to be closed by a valve, for the admission of atmospheric air, could convert it into an inhaling apparatus. Upon second thought I had an impression that ether would dissolve India rubber, and put the question to Mr Wightman. He thought it would. I then put the same question as to oil silk.

Wightman, it is said, advised him to get the opinion of a chemist, suggesting that he consult his former preceptor, Dr Jackson, who was a chemist and geologist of note as well as a physician. This Morton did, and the interview, which was based on certain inquiries concerning ether, provided Jackson with what he regarded as a conclusive argument in favor

*The late William W Ford, M.D., D.P.H., was emeritus professor of toxicology, School of Hygiene and Public Health, Johns Hopkins University.

of his own later claim to priority of discovery. At about that time Morton also conferred with N B Chamberlain, an instrument maker of School Street, in regard to inhalers.

Dr Jackson, perhaps recalling Faraday's² statement, "A convenient mode of ascertaining the effects is obtained by introducing a tube into the upper part of a bottle containing ether, and breathing through it," had first suggested a simple flask with a glass tube inserted in it. Morton reported that he attempted to employ this device in a self-experiment shortly before his operation on Frost but completed the experiment by inhaling the ether from his handkerchief. Jackson later advised the use of a flask

the apparatus, was not yet satisfied. His anxiety, in fact, became so great that on the evening before his demonstration at the hospital he consulted Dr Augustus A Gould, a member of the Massachusetts Medical Society and one of his most sympathetic and helpful advisers. Dr Gould suggested the employment of valves to control the flow of air, and together with Morton and Wightman spent the better part of the night making sketches of new apparatus. At daybreak of October 16, Morton took the final design to N B Chamberlain and persuaded him to set to work on it. A little before ten o'clock — the hour of his appointment at the hospital — he left Chamberlain's shop carrying a new

FIGURE 1 Morton Ether Inhaler (1846)

This model is the one generally considered to have been used by Dr Morton at his first public demonstration of ether anesthesia at the Massachusetts General Hospital on October 16, 1846 (Courtesy of the Massachusetts General Hospital)

with a bent glass tube 3 feet long, but this proved unsatisfactory and Morton obtained from Wightman a tubulated globe receiver employed in distillation. A piece of sponge moistened with ether was put in the larger end of the globe, and a wooden tube for a mouthpiece was added, the patient's nostrils being compressed between the thumb and finger of the operator or dental assistant.

After this apparatus had been employed for several tooth extractions, with varying degrees of success, Wightman introduced a cork in the tubulure, through which a dropping tube was inserted, notches having been cut in the cork for admission of air and for pouring the ether. But Morton, always speculating on the possibility of asphyxia from

inhaler, the description of which he³ later published with the following detail

The apparatus [Fig 1] consisted of a glass vessel, about six inches square, with rounded corners, one opening, two inches in diameter, was left on the top through which a sponge was inserted and the ether poured, and another, an inch and a half in diameter, on one side for the admission of external air. On the side opposite the last-named opening was a glass tube, two inches in diameter, and an inch in length, terminating in a metal mouth piece three inches long, and of the same calibre as the glass tube. This mouth-piece was provided with two valves, one covering a circular opening, three quarters of an inch in diameter, on the top, and the other extending across it. These valves were so arranged that, when the patient filled his lungs, the upper valve shut down, closing the aperture in the top of the mouth-piece, while the one across the mouth-piece opened and allowed the ethereal vapor, mixed with atmospheric air, to pass into the lungs, and when he emptied his

lungs the pressure of the expired air closed the valve across the tube, while the same pressure opened the upper valve, and allowed the vapor, which had once been breathed, to pass into the room, instead of returning into the reservoir

Miller⁴ has stated that the principle of Morton's inhaler has been but slightly improved in all the succeeding years. With some modifications the instrument was employed by Morton for the first six months after the discovery of anesthesia, he then turned to the use of the sponge

Accompanied by Eben H. Frost, as a former patient who had successfully inhaled ether on September 30, 1846, Morton, out of breath and a quarter of an hour late, on the historic morning of October 16 reached the surgical amphitheater in the Bulfinch Building of the Massachusetts General Hospital, where the assembled surgeons, medical students and the patient, Gilbert Abbott, a frail youth of twenty in a plush upholstered reclining chair, awaited his coming. After Morton had given Dr. Warren — who was on the point of operating without further delay — the reason for his tardiness, he filled the new inhaler with ether mixed with "French essence" to disguise its odor and anesthetized Abbott, with the success attested to by Dr. Warren's never-to-be-forgotten remark, "Gentlemen, this is no humbug."

Following the demonstration Morton was invited by the surgeons to administer ether for an operation on October 17, but before doing so he acted on a suggestion of Dr. Gould's concerning a still better valvular system for his inhaler, with the result that the second operation (the removal of a fatty tumor from a woman's arm) was even more successful than that of the preceding day. After these trials the use of the anesthetic was discontinued at the hospital until November 7.* In the meantime, Morton devoted himself to giving ether in his dental practice and soon had a record of one hundred and sixty dental operations to his credit. Within a few weeks he found it necessary to enlarge his office and take all the space available at 19 Tremont Row.

On November 7, 1846, came the supreme test of Morton's remedy — an amputation of the thigh. "Everybody awaited this test by amputation, and then only was the accumulated evidence deemed conclusive," wrote Henry J. Bigelow.⁶ Dr. Bigelow, who was present at the operation of October 16 and witnessed several dental operations in Morton's office, announced the great discovery in a paper read before the Boston Society for Medical Improvement on November 9. But previous to that date, on November 3, he had read an abstract of the paper at a meeting of the American Academy of Arts and Sciences, and the paper in its entirety was pub-

lished in the *Boston Medical and Surgical Journal* of November 18, 1846.⁷ Less than a month before, this journal⁸ had printed the brief notice later to be so frequently quoted: "Strange stories are related in the papers of a wonderful preparation, in this city, by administering which, a patient is affected just long enough, and just powerfully enough, to undergo a surgical operation without pain." This was the first notice of anesthesia to appear in any medical publication.

Morton, endeavoring to keep his compound a secret one, had been informed, prior to the amputation of November 7, that the surgeons must be told the nature of the substance used before its further employment at the hospital, and in a letter to Dr. Warren — whom he had already informed — he had made the announcement that he was employing sulfuric ether. The mention of sulfuric ether also occurred in the patent for the discovery, applied for jointly by Morton and Dr. Jackson on October 27, 1846, and granted on November 12 of that year. Morton, however, still lacked a specific name for his compound, and a meeting was held at Dr. Gould's house on November 20 for the purpose of selecting one. "Letheon" (derived from a Greek word *lêthê* meaning oblivion, the name of one of the rivers of hell, of which the souls of the dead were supposed to drink, inducing forgetfulness of the past, after they had been for a certain time confined in Tartarus, a region of Hades) was on a list of names submitted and was immediately chosen by Morton. The term "anaesthesia," likewise of Greek origin, did not seem to interest him when it was proposed on the following day by Dr. Oliver Wendell Holmes, who had been present at the meeting.

Letheon served both as a name for ether and as a designation for the unique series of advertisements, circulars and pamphlets relating to the discovery, that Morton published from the latter part of November, 1846, to May, 1847, some of the earliest of these notices appearing in the advertising pages of the *Boston Medical and Surgical Journal* and the *Boston Evening Transcript*. The first description of the Letheon publications, some of which have become excessively rare, was given by Benjamin Perley Poore⁹ in *Historical Materials for the Biography of W. T. G. Morton*, published in 1856. In 1858 practically the same account appeared in Nathan P. Rice's *Trials of a Public Benefactor*.^{10†}

Terms derived from Letheon also served to designate the ether inhaler and the method of administering the drug, namely "letheonic apparatus" and "letheonising." These terms were used, perhaps for the first time, in the communications of James A. Dorr, an American residing in London and one of the special agents employed by Morton while he was attempting to enforce his patent here and

*According to Hodges,⁵ Morton never gave ether for more than five or six operations at the Massachusetts General Hospital, although he consented to administer it to some extent for operations performed by the hospital surgeons and others in private practice. Dr. Henry J. Bigelow, having conducted extensive experiments and become thoroughly familiar with the use of ether anesthetized the majority of patients undergoing operations at the hospital during the year following the introduction of anesthesia.

†A bibliographical description of these publications listing them for the first time in the order of their appearance, has been given by Dr. John F. Fulton under the title, *The Morton and Warren Tracts on Ether (Letheon)*, which was published as an appendix in *The History of Surgical Anesthetics* by Thomas E. Keys (New York: Schuman's, 1943).

abroad and to control the use of ether by the sale of licenses and inhalers for its administration in surgery. By virtue of his identification with the Letheon pamphlets, the most prominent of these agents was Edward Warren,* who represented Morton's interests in Washington and Paris and edited three editions, running into five issues, of the pamphlets under the title, *Some Account of the Letheon*.

Despite strong medical opposition to anesthesia, exemplified in a much-quoted editorial, with its charges of quackery, in the *Philadelphia Medical Examiner* for December, 1846, as well as similar pronouncements in such publications as the *Annalist*,¹²⁻¹⁴ a New York journal, and the *New Orleans Medical and Surgical Journal*,¹⁵ — to say nothing of attacks by the dentists, headed by Dr J F Flagg, of Boston, — Morton's inhaler was widely distributed. Through his own efforts or those of his agents, it appears to have come into fairly extensive use in this country within four or five months after his initial demonstration of ether. The use of the instrument, together with ether, was offered free to all charitable institutions.

The drug was employed at an early date for several operations, including an arm amputation, by Dr Abel L Peirson, the leading surgeon of Salem and Essex County, whose report of his cases¹⁶ — all successful — was the first account of private surgical operations under anesthesia to be published. Dr Peirson's use of Morton's inhaler is implied by the statement that the anesthetic was administered by a dentist, Dr Fisk.

Among the first surgeons of prominence outside of New England to make use of the instrument was Valentine Mott, of New York City, who tested it with success in operations for tumor and anal fistula in December, 1846, the earliest of these being performed on December 8. Other operations were performed in New York City by Dr A L Cox,¹⁷ an early and enthusiastic advocate of Letheon. All the first experiments there were supervised by Dr Horace Kimball, a dentist, who acted as Morton's agent and used the apparatus in his own practice. About the middle of January, 1847, ether analgesia by means of the inhaler was tried at the New York Hospital. But the existence of the patent and the concealed nature of the remedy — for even when it was known to be sulfuric ether a certain aura of mystery surrounded its preparation for a time — rendered Letheon unpopular in New York and hampered the immediate adoption of anesthesia in that city.

With the spread of anesthesia in the South and West during the winter of 1847, Morton's inhaler was introduced in such cities as New Orleans, St Louis and Cincinnati, the instrument, strangely enough, figuring in a fatal case of chloroform in-

halation† occurring in Cincinnati a year later. The early tests of ether in these cities were apparently highly successful, and in New Orleans the editors of the *New Orleans Medical and Surgical Journal*, who had witnessed the first operation under ether there — a thigh amputation performed at the Charity Hospital on February 25, 1847 — promptly reversed their unfavorable judgments concerning the discovery.

In Georgia, where Dr Crawford W Long performed the first surgical operation under ether anesthesia in March, 1842, using a saturated towel and from time to time performed other operations under the drug but did not publish his findings until 1849,²¹ successful experiments, with a handkerchief the favored means of administering ether were conducted at the University of Georgia and the Georgia Medical College following the announcement of Morton's discovery. Paul Fitzsumner Eve, professor of surgery at the Georgia Medical College, co-editor with Dr I P Garvin of the *Southern Medical and Surgical Journal* and one of the vice-presidents of the National Medical Association, appears to have been the first of the Georgia physicians to investigate the discovery at this time, making inquiries concerning it as early as November, 1846.²²

Some tests of ether took place in Baltimore in the late autumn of 1846, although the first Maryland physician to adopt the use of anesthesia was a young surgeon in Frederick, Samuel M Tyler.²³ The early Baltimore experiments were not so successful, perhaps owing to impurities in the ether. A handkerchief or sponge in preference to the inhaler was employed there, as in Philadelphia, where the first surgical operation under the drug — a finger amputation performed by Dr William Gibson — did not occur before May, 1847. According to Parrish,²⁴ however, a number of reputable Philadelphia dentists had employed ether regularly in their practice for several months previous to that date.

As stated earlier, a number of inhalers made their appearance in this country shortly after Morton's late in December, 1846, — a time when ether was often referred to as the "new gas," — the *Boston Medical and Surgical Journal* published²⁵ the following

In the face of the patent instruments used in administering the gas, made principally of glass, with metallic fixtures, such as a mouth piece, valves, etc., are manufactured in this city to a great extent. One person assured us that the demand far exceeded his ability to manufacture the article. Several individuals not only advertise that they prepare the *air of forgetfulness*, but that they have the apparatus also — and from what is bruited about the town, a thriving business is conducted by those who stand in no fear of patents. Some of the artists consider that the administration, only, was secured by the

*Warren's own dislike for the term "agent" as applied to his association with Morton was expressed in a contemporary issue of the *Boston Medical and Surgical Journal*.¹¹

†That of Mrs Martha G Simmons, thirty-five years of age, and apparently in good health, who died within ten minutes after inhaling chloroform for a dental operation. The anesthetic was inhaled from a saturated sponge placed in Morton's apparatus and filling about a third of the glass globe. This fatality, which occurred on February 23, 1848, and was reported in full in the *Western Lancet*¹⁸ and the *St Louis Medical and Surgical Journal*, attracted wide attention.

patent, and not the instrument, others are of the opinion that such a gas-holder as they produce, is no infringement of a right secured to others, inasmuch as their work is an invention of their own

It appears that not a few inhalers reached the Massachusetts General Hospital "After its acceptance of the discovery," wrote Hodges,²⁶ "the hospital was overwhelmed with inhaling apparatuses of

ber 13 of that year, however, he and Dr Augustus A Gould took out a patent for an apparatus* "to be used for the purpose of administering to persons or introducing into their lungs the vapors of ether or various other chemical matters" Features of this inhaler included an evaporating vessel with a special system of induction and eduction valves, a

FIGURE 2 Morton and Gould Ether Inhaler (Photograph from United States National Museum)

This was protected by U S patent 5365, issued on November 13, 1847 The model is entirely made of tinned metal, with the exception of the cork used as a stopper in the metal reservoir (which could also be made of glass or other suitable material) and the sponge The mouthpiece, with a supporting flange or lip, is shown on the left, attached to the evaporating vessel, which contained the sponge

every device and size — most of them cumbersome and expensive — sent them by the makers It is to be regretted that these contrivances were not preserved, as they would now be interesting curiosities"

Morton himself, at first sufficiently persuaded that the inhaler was the best means of administering ether, if not indispensable to the success of his discovery, contracted for hundreds of sets of apparatus, as well as globes, retorts and other glassware for each modification of his instrument All these were to be left valueless on his hands with the adoption of the conical sea sponge, employed at the Massachusetts General Hospital by J Mason Warren²⁷ in March, 1847, and introduced in England at about the same time Morton bowed to the inevitable and substituted the sponge for his inhaler, warmly praising this new medium in a letter to the *Lancet*, published July 17, 1847 On Novem-

ber 13 of that year, however, he and Dr Augustus A Gould took out a patent for an apparatus* "to be used for the purpose of administering to persons or introducing into their lungs the vapors of ether or various other chemical matters" Features of this inhaler included an evaporating vessel with a special system of induction and eduction valves, a

* * *

Meanwhile the instrument makers in Europe had not been idle The news of the discovery had reached London in the middle of December, 1846 On November 28, Dr Jacob Bigelow, the father of Dr Henry J Bigelow, sent a letter giving an enthusiastic account of the ether demonstration and subsequent operations at the Massachusetts General Hospital to Dr Francis Boott, of London, a physician with many Boston affiliations and Bigelow's personal friend He likewise dispatched a copy of the *Boston Daily Advertiser*, which contained an

*A model of this apparatus in tinned metal is now in the Smithsonian Institution, United States National Museum A complete account of it has been given by Dr George B Roth²⁸ It is here reproduced (Fig. 2) through the courtesy of Mr J E Graf assistant secretary and Dr Charles Whitebread associate curator of medicine, Smithsonian Institution

article by Dr Henry J Bigelow announcing the discovery, first published in the *Boston Medical and Surgical Journal* of November 18. Receiving these communications on December 17, Dr Boott lost no time in informing his associates, including the Gower Street dentist, James Robinson. Private letters from Dr John C Warren and Dr John Ware sent to the *British and Foreign Medical Review* reporting the discovery were also received about that time, and the inhalation of ether became the "all-engrossing subject."

On December 19, Robinson gave ether to Miss Lonsdale, a relative of Dr Boott's, and painlessly extracted a molar tooth. The inhaler used on this occasion consisted of the lower part of Nooth's apparatus (used for making soda water) with a flexible tube, to which was attached a ball-and-socket valve and a mouthpiece resembling those generally employed for inhalation. It was later referred to by Robinson²⁹ as "a very imperfect apparatus, hastily got up, and which was condemned from its ill success in cases on the 20th." Another form of the inhaler was promptly devised by Dr Boott and Robinson and made by William Hooper, a chemist and instrument maker in Pall Mall.

Employed in many of the earliest experiments carried out in London and undergoing various modifications, the inhaler in its general form consisted of two stoppered glass vessels, taken from the popular Nooth's apparatus. The vessels contained pieces of ether-saturated sponge, cut into triangular shapes and arranged in such a manner as to present as large a surface as possible for the rapid evaporation of the ether. The vapor was conveyed through an elastic inhaling tube, with a pad to be held over the mouth to prevent the breathing of free "atmospheric air," a point stressed by the designers. The pad was kept in place by the operator or his assistant. A stopcock attached to the mouthpiece regulated the volume of the ether vapor, and a nose spring, which practically all European inhalers featured in one form or another, compressed the nostrils when necessary.

This instrument was well publicized during the first months of ether inhalation in Europe, reproductions or references to it appearing in the *Illustrated London News* of January 9, 1847, the *Lancet* of January 16, the *London Medical Gazette* of January 29, the *Gazette des Hôpitaux* of February 13 and other journals. A cut of the inhaler in its improved form was also reproduced in Robinson's *Treatise*, published in the spring of 1847.

On the day of the first tooth extraction — Saturday, December 19 — Robert Liston, informed of the discovery by Dr Boott, called on his friend Peter Squire, a well known London chemist, with the unusual request to have an inhaling apparatus made ready for a surgical operation — an amputation of the thigh — to be performed under ether narcosis on the following Monday. It was then past mid-

day, but Squire met the emergency. Like Robinson, he employed a Nooth's apparatus. The upper detachable cylinder was packed with pieces of sponge, and a flexible tube with an ordinary bronchial inhaler mouthpiece was fastened to the exit, the patient's nostrils being held by the fingers. Saturating the sponges with ether, Squire, after some preliminary difficulty, completely anesthetized his nephew, William Squire, later Dr William Squire, F R C P, who had volunteered his services as a subject for inhalation.

On December 21, 1846, the first successful surgical operation under anesthesia in Europe, so graphically described by F William Cock,³⁰ took place at the University College Hospital in London. Liston, then at the height of his distinguished career but to die before another year was out from an aortic aneurysm, amputated the limb with his accustomed skill and rapidity after the patient had been placed under the influence of ether by William Squire, using the elder Squire's inhaler. Among the students thronging the amphitheater on this occasion and hearing Liston — wildly enthusiastic — predict that in six months no operation would be performed without ether was Joseph Lister.

Within the next few days James A. Dorr informed the medical profession and the public of Morton's patent rights by means of a letter addressed to the *Lancet* stating, "that the process for procuring insensibility to pain by the administration of the vapour of ether is patented for England and the Colonies, and that no person can use that process, or any similar one, without infringing upon the rights legally secured to others." This statement was published with other early notices of anesthesia that appeared in the *Lancet*.³¹

The patent at once became the cause of a great deal of unfavorable comment and misunderstanding in Europe, as it had in this country, and efforts to have it recognized met with little success, as may be judged from the following notice of Dorr's,³² issued on January 30, 1847, and printed in the *Pharmaceutical Journal and Transactions* under the heading "Letheonic Apparatus."

I feel it to be a duty to inform the Medical and Surgical Profession, and the Public in general, that in order to insure the safe use of the Letheon, certain conditions rigorously are necessary in the apparatus employed. It is possible to strangle instead of letheonising, and I would therefore urgently advise every operator, whether licensee or infringer, to be careful that all the air-passages of the apparatus used be of large diameter. This diameter should not be in any part less than three-eighths of an inch bore, and particular attention should be given that there is no obstruction to the free circulation of air or vapour through the valves. I regard the practice of compressing the nostrils of a patient, by means of a spring or other instrument, as highly dangerous and improper. The nostrils should be closed by the fingers of a prudent and experienced person. *Asphyxia and etherisation are two very different things.* It is trusted that no one will be so ungenerous or so unwise as to construe this information, which is communicated from motives of humanity, into an abandonment of any lawful claim.

his was signed by Dorr as agent for the proprietors of the *Letheon*

Other notices and letters of Dorr's in defense of his patent and Morton's claims to priority of discovery, several of which were published in the *Lancet*, continued to be issued during the winter of 1847. He also prepared, according to Rice,³³ a number of sets of expensive apparatus with full instructions for their proper use. These, in accordance with the custom prevailing in monarchical countries, he forwarded in Morton's name to the principal European rulers, as well as to many surgeons of prominence.

Following Liston's trial of anesthesia, Peter Squire reconstructed his inhaler, employing special patented valves (Read's valves), so arranged as to prevent the expired air from returning into the apparatus, a ferrule near the mouthpiece for regulating the quantity of air admitted and a spring for closing the nostrils. The inhaler, a glass urn, was supplied with ether at the top by means of a metal funnel that formed part of the stopper of the urn. The ether fell through a nozzle and was distributed in a shower on the sponge. Too rapid evaporation of the anesthetic was prevented by the patented valve in this part, which admitted air at each inspiration and then closed instantly. The mouthpiece, made at first of wood and later of glass or metal, was constructed to fit the mouth and entirely enclose it.

With all its carefully executed detail, this apparatus was one of the more elaborate, if not the most costly, of the many inhalers exhibited and discussed at a meeting of the Pharmaceutical Society held in London on January 13, 1847, — when interest concerning the successful administration of ether by an instrument was at its height. The meeting was well attended, the lecture room of the society being crowded with members and medical men who had gathered to hear Squire read a paper³⁴ that presented a general discussion of the subject of inhalation and gave an account of his own instrument (Fig 3), which became one of the principal English inhalers of the period.

Dividing the honors with Squire's apparatus was the inhaler of Boott and Robinson, also exhibited on this occasion and discussed by Hooper, who had introduced several modifications and offered it as an instrument employed in a large number of cases without failure. An elaborate system of valves and an improved nasal spring had been added to Nouth's glass apparatus. A special feature was the reconstructed pad for the mouth, this pad, later described by Robinson³⁵ in his treatise, was so flexible that by pressing its edges the operator could fit it to a mouth of any size without difficulty. It was made of thin sheet copper, covered with soft leather on the inside, which was thickly stuffed and padded with wool. An opening in the center of the pad provided for an ivory or amber mouthpiece to be screwed on and kept in the mouth during inhalation.

An instrument with similar features continued for some time to be manufactured by Hooper and bore his name.

Other forms of apparatus shown at the meeting, a number of which were subsequently reproduced in the *Pharmaceutical Journal*, included a wide variety of urns, jars, cylinders and funnels, with fittings of amber, ivory, brass, ebony, pressed steel, tin and vulcanized rubber. Bladders were also in favor and

FIGURE 3 Squire's Ether Inhaler (1847)

were recommended for the use of dentists on account of their simplicity. They possessed the additional advantage of not being protected by patents or caveats. Ivory mouthpieces were popular, and silver was also used in some instances. A mouthpiece of glass was advocated by Jacob Bell, editor of the *Pharmaceutical Journal*, who³⁶ expressed the opinion that some persons might object to apply to their mouths a pad or wooden tube saturated with moisture from the patient who had used it last. The glass mouthpiece could be removed and as easily washed as a cup or wineglass.

Interested in obtaining a simple apparatus that would serve its purpose economically, since many instruments had been designed without thought of the expense, Bell had constructed an inhaler from an ordinary green quart bottle. This had a bung with two openings, through one of which a glass tube for conveying the ether vapor passed nearly to the bottom of the bottle, the other opening being

fitted with an inhaling tube and valves. The glass mouthpiece, similar in form to an eyeglass or cup, although somewhat larger, was to be added to the inhaling tube. In place of a sponge a little water was introduced into the bottle with the ether, through which the bubbles of air passed from the lower end of the glass tube, thus becoming saturated with the vapor. This apparatus, as exhibited at the meeting, was recommended as one easily put together by a surgeon in the country who could not command the facilities of a London hospital. A modified and more elaborate form of this apparatus (Fig. 4) was later brought out by Gilbertson, a London designer who had assisted Bell in the production of the first instrument. In the illustration two types of glass mouthpiece are seen.

Bell believed that skill and practice were prerequisites to the really successful inhalation of ether, so that failure in some cases should not always be

FIGURE 4 Gilbertson's Ether Inhaler (1847)
Two types of glass mouthpiece are to be seen on the left

attributed to the instrument employed, an opinion that Squire had also expressed and one that was shared by others at that time.

Still another form of simple apparatus with an element of novelty was an adaptation of the German pipe, offered by Tracy, of St. Bartholomew's Hospital, who during the course of some seventy or eighty tooth extractions had first tried many of the usual types of inhalers. The general efficacy of these instruments when properly employed he considered as being on a high level, for when failures had occurred he believed, with Squire and Bell, that the patient was perhaps at fault. But he regarded the size of most of the inhalers as an objection, especially in the extraction of teeth, a procedure in which the operator should be able to administer the vapor without the aid of assistants and easily dispose of the instrument when the patient was once under the influence. Therefore, with the hookah first in mind, Tracy had adopted the German pipe as meeting

the desired requirements. This pipe (Fig. 5) was made of glass, mounted at the top with a brass cap and stopcock, into which was screwed a sixteen-inch elastic tube. The tube was surmounted by a double-valve mouthpiece, and a padded steel compress

FIGURE 5 Tracy's Ether Inhaler (1847)
This is constructed on the lines of a German pipe

served for securing the nostrils. As much ether was poured into the pipe as would fill the well and saturate the sponges. The mouthpiece was placed between the patient's teeth, the stopper removed, the stopcock turned on, and the patient directed to inhale in the natural way. In subsequent accounts of the instrument, Tracy³⁷ stated that he had used it for a large number of operations and had found it better than any other apparatus he had employed.

The inhaler had been constructed by Ferguson, the instrument maker to St. Bartholomew's Hospital, who had supplied all previously used by Tracy and was among the designers having three or more varieties of inhalers on display at the meeting. Reporting on this meeting, the *Lancet*³⁸ published the following comment in regard to the number of instruments shown, "they were really so numerous, that it would appear that the whole scientific portion of the members of the Society, as well as that of many others, had been employed in inventing and contriving means for administering the vapour of ether." Nevertheless, still more inhalers were to be introduced, including John Snow's water-heated apparatus, of which there will be further mention.

Such instruments as Startin's "Pneumatic Inhaler," with a brass nose spring and a special fumigating device, which could be substituted for the

ether chamber or reservoir of the inhaler, some other substance than ether being employed, came into popular use for a time, as did two inexpensive tin inhalers, one of them portable (Fig. 6), devised by Alfred Smee, F.R.S. The portable inhaler — one of the earliest — was severely simple, consisting of

FIGURE 6 Smee's Portable Ether Inhaler (1847)

little more than a metal mouthpiece to which was attached a small pouchlike receptacle of the same material for holding the ether and sponge. In the first form of this instrument, however, no provision

FIGURE 7 Salt's Portable Ether Inhaler (1847)

The top was pulled out and the ether was poured on the sponges in the metal cylinder, the top then being replaced. With the air holes either partially or entirely exposed, the inhaler was then ready for use.

had been made to prevent the possibility of the ether from running into the mouth during inhalation. Hedley's wooden inhaler, although not classified as portable, was another compact instrument. It was a cylinder about nine inches in length, shaped

at one end to form a mouthpiece and made of box-wood, lignum vitae or cherry, with valves of the same material. The latter were placed near the mouthpiece, the ether being received from a sponge introduced into the body of the instrument. More elaborate, but advocated as of convenient size and form for the pocket, was Salt's portable inhaler (Fig. 7), produced at Birmingham. By means of a revolving plate with corresponding openings, fitted into one end of the cylinder or body of the apparatus, and through the alternate admission of air and ether, the volume of the vapor could be regulated without removing the instrument from the mouth. The other end of the cylinder was fitted with a revolving tube, which also had corresponding apertures for controlling the quantity of air admitted. To prevent evaporation, both ends of the apparatus could be closed when it was not in use.

Gallard's portable instrument (Fig. 8) was a cylindrical tin box, the lid of which contained an

FIGURE 8 Gallard's Portable Ether Inhaler (1847)

a is the cylindrical tin box, b, a tube of sufficient caliber to permit a two-ounce bottle of ether to be packed in it, thus forming a case, c, the mouthpiece and valves, d, one of the caps to tin tube used as a bottle case, and e, the brass clip for closing the nostrils.

adjustable hole for the admission of air in almost direct communication with the tube. The box itself also had an adjustable hole for admitting air in closer connection with the ether. The tin inner lining of the box, which was conical in shape, allowed two or three ounces of ether to remain in it without spilling, whereas a small inside tube provided for the ether to be poured back if not wanted. A mouthpiece, valves and a brass nose clip, not unlike a pair of sugar tongs, completed the apparatus. All parts of it, with the exception of the tube, were made to fit into the box. When opened, the larger hole supplied the ether vapor in diluted form, and the smaller one a much more concentrated vapor. The holes could be closed during each expiration.

but were supposed to be opened by the anesthetist before each inspiration

A variety of portable inhalers — some as small as four and a half by two inches — were soon being made. They were regarded as especially appropriate for women and, fitted into morocco or other suitable cases, proved popular at gatherings where ether was inhaled for exhilarating purposes only. Portable models that had the basic features of their principal inhalers were brought out by Squire, Hooper and later by John Snow. Hooper likewise designed what was perhaps the first inhaler for horses. This instrument was formed of a specially constructed muzzle with inhaling tube and valves, with a vulcanized rubber bag attached for holding the ether and sponge. The whole was adjusted to the animal by means of a headpiece, similar to a bridle, and a tightly fitting rubber band placed over it near the top.

Squire's large inhaler was apparently the first to come into use in Edinburgh. The instrument had been dispatched by Liston to his friend James Miller, who performed the initial operation under anesthesia in Edinburgh at the Royal Infirmary.³⁹ This took place about the middle of January, 1847. The discovery excited great interest among the Scots and various forms of inhaling apparatus were soon being tested — although not always successfully — in surgical procedures. In Edinburgh, as in Dublin,* a simple form — the glass jar or flask variety, with or without valves, seemed to be the preferred type of inhaler and was chosen by such men as James Y. Simpson and James Syme.

Simpson, who introduced the use of ether in obstetrics on January 19, 1847,⁴¹ employed a portable glass flask without valves, which contained ether, poured on a piece of flannel or other absorbent material. The flask had a mouthpiece and an aperture in the side to admit air. He continued to make use of this device or a concave sponge in administering ether until his introduction of chloroform anesthesia in November, 1847,⁴² when he gave the anesthetic on a handkerchief. (In his original patent of 1846, Morton, it may be said, had listed both the sponge and the common glass flask as among the effective methods of giving ether.)

Syme, prompt in his employment of anesthesia as he was in his later adoption of asepsis, following the precepts of his son-in-law and greatest pupil, Joseph Lister, used practically the same ether apparatus as did Simpson. But he had previously experimented with other apparatus, which gave such poor results that he⁴³ states, "in common with many members of the profession, who had experienced similar discouragement, I resolved to abandon the use of ether, at all events until better results could be obtained." After the advent of John Snow in the field of anesthesia and his success, Syme was suf-

ficiently encouraged to recommence his own employment of ether, which he did successfully, although, one of the first besides Pirogoff to adopt anesthesia in Europe, he maintained a somewhat conservative attitude in regard to its uses for a time.

James Kemp, a philosophical instrument maker of Edinburgh, constructed a portable inhaler that was included among five principal inhalers listed by the *Edinburgh Medical and Surgical Journal*⁴⁴ in the following order: Squire's ("the one most commonly employed in the Metropolitan hospitals and in London generally"), Snow's, Startin's, Robinson and Boott's, and Kemp's.

Kemp's inhaler, fitted into a case ten inches by four, was similar to the German pipe of Tracy's apparatus and consisted of three parts — a strong bent syphonlike tube for holding the ether, a stopcock for preventing evaporation when the instrument was not in use, a flexible tube with the usual inspiratory and expiratory valves and a mouthpiece. The tube could be made of glass, block tin, brass or any other suitable material, and was large enough at the base to hold the pieces of sponge. Especially recommended was the inhaling tube, of the same size as the trachea, which allowed the patient to breathe through it freely and became "a continuation of the windpipe," as the different parts of the apparatus such as the stopcock, valves and mouthpiece, were all of the same dimension. The mouthpiece was of ebony but could be constructed of glass or earthenware. The all but inevitable nose spring, made of steel, completed the instrument. A second form of the inhaler was brought out as a table model. The bent tube for holding the ether, of the first design, was replaced by a glass urn mounted on a mahogany pedestal; but the essential parts of both models, including the mouthpiece, were the same. Both were reproduced in the April, 1847, number of the *Edinburgh Medical and Surgical Journal*, together with the inhalers of Squire and Startin.

Although Squire's inhaler was undoubtedly in demand, the administration of ether in London, as previously indicated, was largely in Robinson's hands during the first four or five weeks following the announcement of the discovery. This included both private and hospital practice, as well as a certain number of veterinary operations. Beginning with such painful procedures as the removal of decayed roots of previously extracted teeth, Robinson, using his modified inhaler, was soon giving ether for general surgery at the Metropolitan, King's College, St. Thomas's, Guy's and other hospitals. He apparently met with a considerable measure of success, although, as Sir Benjamin Ward Richardson⁴⁵ stated, the first inhalations of ether in England were "not so successful as to astonish all the surgeons, or to recommend etherization as a common practice." Here we have the echoes of Syme's pronouncements. Richardson's statement

*The first surgical operation under ether in Ireland was performed by J. MacDonnell on January 1, 1847 at the Richmond Hospital in Dublin.⁴⁰

might well have included some of the early trials of anesthesia in France and other parts of the Continent

In England distrust arose from the way in which the anesthetic was administered. It did not always take effect, and fatalities directly or indirectly attributable to the drug were reported. Liston himself was said to have lost much of his early enthusiasm for anesthesia. To offset these failures the administration of oxygen to resuscitate etherized patients began to be advocated. In accordance with this, Hooper equipped his large inhaler with a gas bag,⁴⁶ and by the end of March, 1847, Robinson was giving oxygen, following the administration of ether, as a routine procedure. John Snow at first took an active part in opposing the practice, to be revived later on.

Snow, who was the first physician to specialize in giving anesthetics and the author of the initial textbook on the subject, was six years Morton's senior. He served a long apprenticeship in his profession and was always a serious worker. He had received from the University of London the degree of Bachelor of Medicine in 1843 and that of Doctor of Medicine in 1844. He had engaged in various experimental studies on respiration and asphyxia, the results of which he had published, but he had failed to achieve any prominence. The ether discovery proved to be the turning point in his career.

Soon after the news of the discovery, and without any immediate thought of specialization, Snow carried out experiments on animals and on himself for which his previous work had prepared him. Richardson⁴⁷ records that the deciding factor in Snow's resolve to take up anesthesia was his chance meeting with a druggist of his acquaintance, who, carrying a large apparatus under his arm, informed him that he was getting into quite an ether practice, giving the drug "here, there and everywhere."

By January 23 Snow had perfected an inhaler. This instrument, as he acknowledged, was based on the principles of an inhaler brought out in 1842 by Julius Jeffrey, F.R.S., as an apparatus for the inhalation of "aqueous vapor." A contemporary description of Snow's inhaler, published in the *Pharmaceutical Journal*,⁴⁸ is as follows:

A round tin box, two inches deep, and four or five inches in diameter, with a tube of flexible white metal, half an inch in diameter, and about a foot and a half long, coiled round and soldered to it. There is an opening in the top of the vessel, at its centre, for putting in the ether and attaching the flexible tube belonging to the mouth piece. In the interior is a spiral plate of tin soldered to the top, and reaching almost to touch the bottom. When used, the inhaler is to be put in a hand basin of water, mixed to a particular temperature, corresponding to the proportion of vapour that the operator may desire to give, and the caps being removed, and the mouth piece attached, when the patient begins to inhale, the air gains the desired temperature in passing through the metal pipe, it then comes upon the surface of the ether, where it winds round three or four times before entering the tube going to the mouth piece, thus ensuring its full saturation, and preserving it at the desired temperature. [Snow usually maintained the temperature between 60 and 65° F.] There is no valve or

any obstruction to the air till it reaches the mouth piece, which is of the kind used in other inhalers and contains the valves necessary to prevent the return of the expired air into the apparatus.

With this instrument Snow asked to be allowed to administer ether at St. George's Hospital. He received permission to give it to out patients for tooth extractions, but when the success of his method had been observed for a day or two he was invited to administer ether for a surgical operation. This occurred on January 28, 1847, and shortly thereafter he was administering the drug regularly on operating days. He gave ether with almost unvarying success and soon made his appearance at University College Hospital, where Liston, struck by his quiet authority, took him by the hand. From that time he became the principal anesthetist in London.

Having chosen this field, Snow devoted himself to cultivating it, and the results of his painstaking investigations soon began to be published in a series of papers, appearing chiefly in the *Lancet* and the *Westminster Medical Gazette*, the majority of them having previously been read before the Westminster Medical Society, of which he had long been a member.

Snow's ether inhaler was reproduced in the *Lancet*, the *Pharmaceutical Journal* and other journals, first being shown in the *Lancet* of January 30, 1847. Although remaining basically the same, it underwent several alterations until it reached the form (Fig. 9) that is best known. A complete description of it occurs in Snow's first book.⁴⁹ "The round tin box" of the original design became one of "japanned tin or plated copper, of the size and form of a thick octavo volume." This box served as a water bath when the apparatus was in use, and at other times contained the elastic inhaling tube and facepiece. Snow's improved facepiece, enclosing both the nostrils and the mouth and permitting respiration as the patient might desire, dispensed with the rather formidable nose spring, which he termed "rude." The central part of the facepiece containing the valves was constructed of brass, tinned iron or plated copper, the rest was of thin sheet lead sufficiently pliable, like the mouthpiece of Robinson's inhaler, as to be easily adapted to the features. The lead was covered with silk or glove leather on its outer surface and lined with oil silk where it touched the face. The valves, of vulcanized rubber, were light and so constructed as to rise with the least pressure and close again of themselves, regardless of the position in which the patient was placed. The apparatus was made by Ferguson and later by Matthews, of Lincoln's Inn, and other instrument makers.

A strong advocate of the inhaling apparatus and the control that its use permitted, Snow had not altered his opinion when he published his book in September, 1847, the sponge having then been in use for six months. "The simple sponge is prefer-

able, for all cases, to many of the apparatuses which were in use," Snow⁵⁰ wrote, "but I cannot admit that it is equal to a good apparatus." He considered it an expensive method, since "not one half of the ether which is dissipated enters either the mouth or nostrils of the patient." He spoke of using five fluid ounces of ether in keeping an elderly patient insensible for more than two hours, but he ordinarily employed two or two and a half ounces in his in-

of a child and the administration of anesthesia obstetrics — long a controversial question — thereby firmly established

* * *

Although bladders, either ox, sheep or pig, were frequently in use on the Continent and were advocated by Schuh, of Vienna, and others, the production of inhaling instruments quickly followed

FIGURE 9 John Snow's Ether Apparatus (1847)

A is a box of japanned tin or plated copper, B, the spiral ether chamber of thin tinned brass or silver-plated copper, C, the opening in same for putting in and pouring out ether, D, a brass tube, five eighths of an inch in internal diameter, by which the air entered, which the patient inhaled, E, another opening in the ether chamber, F, an elastic tube about three feet long, G, the facepiece, H, the inspiratory orifice, I, the same facepiece compressed to fit a small face, and S, a section of the spiral ether chamber

haler, which was approximately the amount used in most of the early instruments, although this varied somewhat with the age of the patient, children usually requiring less. While conceding that the sponge was the more suitable means in giving ether to infants, Snow used his inhaler with a small facepiece for children of two years and older. He conveyed the impression of not being especially in favor of rectal anesthesia, approved by Roux and first adopted by Pirogoff.⁵¹

With the introduction of chloroform Snow found his book, which had been well received, cast in the shade and turned to his studies of this new agent that he was later to administer, by handkerchief, to Queen Victoria on the important occasion (April 7, 1853) when she first accepted chloroform for the birth

the spread of anesthesia. Any attempt to catalogue them, however, would exceed the limits of this paper. The inhaler first employed by Velpeau, which had been designed by Joseph Charrière, of Paris, well known as an instrument maker, and the apparatus of Dieffenbach's, later reproduced in his monograph *Der Aether gegen den Schmerz*,⁵² may be mentioned as perhaps two of the most important of these instruments.

Largely owing to the efforts of F. Willis Fisher, a Boston physician living in Paris, ether experiments in the French capital antedated those in London by several days, the initial demonstration in a Paris hospital going back to December 15, 1846, when Fisher was invited to administer the drug for an operation at the Hôpital Saint Louis, performed by

Jobert de Lamballe But the attempts to anesthetize the patient failed on this occasion, and other early experiments, including those carried out by Joseph Roux at the Hôtel Dieu and by Joseph-François Malgaigne at the Hôpital Saint Louis, which he reported at the French Academy of Medi-

with the anesthetic given by means of Charrière's inhaler and was regarded as a complete success⁵⁴

Charrière's instrument — at once acclaimed in Parisian journals — was brought out in several forms, including a portable one His principal model at that time was a decanter-shaped glass bottle with

FIGURE 10 Luer's Inhaler (courtesy of the Massachusetts General Hospital)

The glass, cork-stoppered vessel is six inches in diameter with a depth of five and a half inches. In place of a sponge there is a four-and-a-half-inch cotton filter. The silk elastic inhaling tube is fifteen inches in length, with a circumference of three inches. The metal fittings and the mouthpiece, which is three inches long, with a depth of approximately one and a half inches, are apparently of lacquered brass.

cine on January 12, were only partially successful. This was apparently due to defective apparatus as well as a poor quality of ether.

The arrival of one of Morton's instruments, otherwise known as the Boston inhaler, about the middle of January did much to overcome the difficulties. Fisher,⁵⁵ to whom it had been sent, stated not only that he employed it in successfully administering ether but that it served as a model for all the Parisian instrument makers.*

Velpeau, deterred by the previous failures, did not operate under ether until January 22, 1847. This operation, for tumor, took place at the Charité

an unusually wide base containing the ether saturated sponge cut and distributed in sections (Fig 11). He employed valves and the long flexible inhaling tubes so popular with the Europeans (Snow advocated one about three feet in length), as well as cork-padded nose pieces that were possibly a little lighter in their general form than the English variety. Early reproductions of Charrière's inhaler appeared in the January 26, 1847, issue of the *Gazette des Hôpitaux* and in the January 30 issue of the *Paris Gazette Medicale*. References to the instrument and its modifications continued to appear from time to time during 1847, principally in the *Gazette des Hôpitaux*. Charrière's inhaler also attracted favorable attention outside of France and was mentioned by Snow and Dieffenbach among others.

*In the present collection of the Massachusetts General Hospital there are two interesting models of a glass inhaler (Fig 10) by Luer of Paris to record an additional apparatus which bears a certain resemblance to Morton's. Undated, they may belong to a later period but the construction of the flexible inhaling tubes and metal mouthpieces seems to relate them to the early inhalers.

In *Aether gegen den Schmerz*, published about seven months after Heyfelder⁵⁵ had performed the first surgical operation (January 24 1847) in which ether was employed in Germany, Dieffenbach gives evidence of his interest in apparatus. He mentions almost a dozen inhalers, including, in addition to Charrière's, Morton's, which he describes at some length, Robinson's and Smee's. His own instrument with its sponge-filled glass globe, was much like

FIGURE 11 Charrière's Ether Inhaler (1847)

Air was introduced by the tube AE, which connected with the inhaling tube BD, terminating in a metal mouthpiece. C indicates the valves, and G, the nose spring.

Morton's inhaler, the chief difference being the long inhaling tube and the mouthpiece, formed like a shell and made of rubber or horn.

Written from the viewpoint of the practical surgeon, Dieffenbach's monograph as a work on inhalation anesthesia was probably the most elaborate of its kind to appear at that time. His death occurred in November, 1847, when interest was beginning to shift to chloroform as an analgesic and when new and simpler apparatus for administering it were soon to be devised by Snow, Squire, Hooper, Smee, Charrière and many others. The ether inhalers that had not already been replaced by the sponge were for the most part set aside at about that date, to be revived, nevertheless, in the years ahead.

HEALTH BILLS PENDING IN CONGRESS*

Part Three

FRANZ GOLDMANN, M D †

NEW HAVEN, CONNECTICUT

IN ADDITION to the National Health Bill, many other proposals are pending in Congress. They deal with construction of essential medical-care facilities, organization of health-service programs and promotion of medical research and professional education. Some of these measures are complementary to the National Health Bill, and some are alternatives to it.

HOSPITAL SURVEY AND CONSTRUCTION BILL

Description

The Hill-Burton Bill, or Hospital Survey and Construction Bill (S 191), is designed to assist the states in surveying their needs for construction of necessary hospitals, developing programs to meet existing needs and building public and other non-profit hospitals in accordance with such programs.

To attain these objectives the adoption of a number of fundamental principles is proposed. A balanced program of hospitals and related facilities is to be developed throughout the country. It includes public-health centers, various types of hospitals — namely, general, tuberculosis, mental and chronic-disease hospitals and other types — and facilities such as laboratories, outpatient departments, nurses' homes and training facilities for nurses. Instead of calling for the building of federal hospitals, the bill proposes to assist the states in developing hospital programs, this assistance being confined to public and nonprofit hospitals and related facilities. The first step to be taken by the states would be a survey of all medical-care facilities within its boundaries. This inventory would be followed by the formulation of a state-wide building program. The project would have to be submitted to the federal authority in charge and, if approved, would be subsidized by federal grants-in-aid.

The number of beds to be provided under the terms of the bill is defined in detail. The total of general hospital beds for any state is not to exceed $4\frac{1}{2}$ per 1000 population, except that in states having less than 12 and more than 6 persons per square mile, the limit shall be 5 beds per 1000, and in states having 6 persons or less per square mile, $5\frac{1}{2}$ beds per 1000. The total number of beds for tuberculous patients is not to exceed two and a half times the

average annual deaths from tuberculosis in the state over the five-year period from 1940 to 1944, inclusive. The total number of beds for mental patients is not to exceed 5 per 1000 population and that for chronic-disease patients 2 per 1000. The number of public-health centers is not to exceed one per 30,000 population. It should be borne in mind that these figures refer to projects assisted by federal funds. To assure the building of qualitatively adequate hospitals the bill requires the formulation of general standards of construction and equipment for hospitals of different classes and in different types of location, the establishment by the states of minimum standards for the maintenance and operation of hospitals, state reports on the hospital situation, and approval of state plans. Of prime importance are the bill's requirements that adequate hospital facilities be available to all the persons residing in a state, without discrimination on account of race, creed or color, and that provisions be made for adequate hospital facilities for persons unable to pay for care.

Authority for the administration of the program is vested in the states and — what is most significant — in a single state agency as the sole agency responsible for both the survey and the administration of the hospital plan. At the federal level, the responsibility rests with the Surgeon General of the United States Public Health Service, whose administrative regulations and other functions are subject to the approval of the newly created Federal Hospital Council.

At the state as well as the federal levels advisory committees would be established. The state advisory councils are to include not only representatives of nongovernment organizations or groups and of state agencies but also of the general public. The Federal Hospital Council is to consist of the Surgeon General of the United States Public Health Service as chairman and eight members appointed by the Federal Security Administrator. Five of these members must be experts in hospital and health activities, and three will represent the consumers of hospital services. All appointed members of the council are to serve on a part-time basis. The council is authorized to appoint special advisory and technical committees.

The cost of both the survey and the construction program is to be shared by the federal government and the states. The bill includes an initial appropriation of \$5,000,000 for the surveys and a total of

*This is the third of a series of four lectures on medical sociology given at the Harvard Medical School during February and March, 1946. They were sponsored by the Department of Preventive Medicine and were primarily intended for third year students.

†Associate clinical professor of public health, Yale University School of Medicine.

\$375,000,000 for construction purposes, to be spent over a period of five years. This money will be allotted to the states according to definite schedules. The states are to receive 50 per cent of their own expenses—but not less than \$10,000—for surveys and planning, and from one third to three fourths of their total expenditures for construction. The provisions of the measure are to be incorporated in the Public Health Service Act and thus become an integral part of the law governing the development and administration of health services under public auspices. The Hill-Burton Bill, as described, has been passed by the Senate and is being considered by a committee of the House of Representatives.

Advantages and Disadvantages

For the first time in American history the development of a broad and balanced program of hospital and related facilities is under active consideration. If passed, the Hill-Burton Bill will put an end to the haphazard growth of facilities, with the resultant uneven distribution of all types of hospitals and the deplorable lack of certain special facilities. Due emphasis is placed on quantitative standards. The introduction of the approval system will serve not only to distribute the hospitals better but to improve their quality where indicated. The poorer states are to obtain relatively more financial aid than the wealthier ones. The administrative control is vested in the states, as it should be, and unification of the administration is proposed. The state advisory councils are composed of representatives of all groups concerned and are thus truly democratic. Enactment of the bill will influence the distribution of physicians and related groups, since it provides for the "workshops" so essential to the practice of modern medicine. The quality of medical care can be expected to improve in areas hitherto undersupplied with adequate hospitals.

The value of the bill in its present form is considerably impaired by several shortcomings. The measure does not contain provisions for the maintenance of hospitals and payment for professional services. It is satisfied with reasonable assurance on the part of states applying for grants that financial support will be available for maintenance and operation. To quote a hospital administrator who testified at the Senate committee hearing, "If people are too poor to build a hospital, they'll probably be too poor to run one." Adoption of the Hill-Burton Bill without the simultaneous passage of bills for the organization of payment for hospital and professional services will create serious problems in many areas. The danger of "ghost hospitals" must be avoided.

In vain does one look for a statement on the staffing of the hospitals. The nature of standards for the operation of hospitals is left to the states to determine. Is it not specified whether the hospitals

are to be open to all qualified physicians or to be restricted to some of them, whether they are to provide luxury services, or whether the physician will be permitted to charge unlimited fees. These are questions that require clear answers in the bill.

The proposals concerning the powers and functions of the Federal Hospital Council are contrary to the time-tested principles of sound public administration. Although composed of persons who devote nearly all their time to their private interests, the council has considerable authority, including the veto power, and important administrative functions. The Surgeon General of the United States Public Health Service and the Federal Security Administrator are made figureheads. Yet they are the very persons officially responsible to Congress and the public for the proper use of large sums of tax money. Such an administrative structure is utterly unsuitable. Councils composed of part-time members should exercise advisory functions only.

The bill fails to make reference to regional organization of hospitals. For years, experts in a civilized countries have been contending that the pattern of hospital organization that was satisfactory in the nineteenth century has become obsolete in this age of rapid transportation. The future hospitals should be developed to serve regions rather than political units, a main hospital functioning as the center of an integrated system of district hospitals, rural hospitals and health centers.

Finally, the amount of money to be appropriated appears small, considering the immediate needs for replacement of obsolete buildings and additions.

DENTAL-HEALTH BILL

Senators Aiken and Pepper have introduced a bill (S 1099) designed to amend the Public Health Service Act so as to provide assistance to states in developing and maintaining dental-health programs. The prevention, treatment and control of dental diseases are covered, as well as research in dental health care and pertinent educational projects. The program is to be financed jointly by the federal government and the states, along the lines followed in the past for health services assisted under the Social Security Act.

As it stands, the bill is too indefinite to warrant detailed discussion. Its main value lies in the fact that it directs attention to a sadly neglected field of health service, calls for the inclusion of preventive, therapeutic and educational services in one program, makes provision for research and professional education and proposes incorporation of organized dental-service plans in the Public Health Service Act.

MATERNAL AND CHILD WELFARE BILL

Description

The Maternal and Child Welfare Bill (S 1318) is sponsored by Senator Pepper, and other senators,

including Senator Murray. Its stated objective is to make more adequate provision for the health and welfare of mothers and children and for services to crippled children. The bill is organized in three parts, covering maternal and child health services, services for crippled children and child welfare services.

The maternal and child health services are made available to all mothers during the maternity period and to all children up to twenty-one years of age, regardless of income, race, creed, color, national origin and residence. The program provides for complete health service, which is defined as follows:

"medical, nursing, dental, hospital, and related services and facilities required for maternity care, preventive health work and diagnostic services for children, school health services, care of sick children, and correction of defects and conditions likely to interfere with the normal growth and development and the educational progress of children."

To promote quality of service, the state agencies are required to establish standards for professional personnel rendering medical, dental, nursing and related types of care or service and standards for hospital and other institutional care and services, to provide for adequate remuneration of professional persons and to furnish opportunities for postgraduate training.

The patients are to have free choice of physician, hospital, clinic or health-service agency. Payment to physicians participating in the program is to be on a per capita, salary, per case or per session basis or, in the case of consultations or emergency visits, on a fee-for-service basis. The last-named method would therefore be the exception rather than the rule. In line with principles established under the Social Security Act, approval of state plans is mandatory, and these plans must provide both for financial participation by the state and for a program effective in all parts of it.

The proposed service would be financed jointly by the federal government and the states. The bill makes an initial appropriation of \$50,000,000 for payments to states that have submitted approved plans for developing such programs and providing such care and service, and it defines in detail the schedule for the allotments to the states. The United States Children's Bureau is to have administrative responsibility at the federal level and is aided by federal advisory committees. State agencies are to be the heart and center of the proposed administrative organization, and they are to be assisted by general advisory councils, composed of representatives of the public as well as of the professions and agencies and by technical advisory committees.

The services for crippled children are to be expanded by adoption of the same basic policies as those proposed for the extension of maternal and child health services. The initial appropriation for grants to states is set at \$25,000,000.

The child-welfare services are designed to curb delinquency, and their extension is to be financed by an initial appropriation of \$20,000,000.

Advantages and Disadvantages

A bill dealing with maternal and child health service is certain to find a sympathetic response. As Sir George Newman once wrote, "The safeguarding and nurture of motherhood and child life must be a first requirement in the building of any nation." What, then, are the relative merits of the health provisions of the Maternal and Child Welfare Bill?

The measure would make service available to everyone without discrimination, provide for completeness of service and develop the program gradually over a ten-year period so as to stimulate the improvement of standards as well as of essential facilities and services. These are highly commendable features. But the bill also has many weak points.

The health provisions of the bill are a halfway measure, since one age group and one condition — maternity — are singled out. The family is divided, and this is contrary to the basic principle of serving the family as a unit. The demarcation by age is artificial and poses intricate administrative problems. The people to be served will wonder why a married woman gets medical care when she is pregnant but not when she is sick, and why persons older than twenty-one are excluded. It would be wiser to concentrate on the passage of a health bill designed for both children and adults and covering all health conditions.

There is little in the bill concerning the organization of professional services. No definition of professional personnel is given, in contrast to the National Health Bill, which clearly states that licensed physicians, dentists and nurses shall be qualified to render service. Does this omission imply that nonmedical practitioners can expect to be admitted? The term "group practice of medicine" does not appear in the bill. This is all the more regrettable because effective child-health service requires organized teamwork by specialists and general practitioners.

The funds for the support of the program are to be obtained by general taxation. This raises the old question of the relative merits of general taxation and insurance.¹ In deciding on the future policy utmost care should be taken to avoid the establishment of two systems of raising funds for the support of services for self-supporting people.

The sum to be appropriated is extremely modest, to say the least. The amount of \$50,000,000 for distribution to the states in the first year exceeds the allocations for the program for the wives and infants of enlisted men (EMIC) by only \$7,000,000. It is hard to see how a program for all the mothers and all the children in the country can be operated

with the funds suggested, even if the birth rate should decline in the years to come

THE NATIONAL MENTAL HEALTH BILL

The National Mental Health Bill (HR 4512), introduced by Representative Priest, supersedes an earlier bill, the National Neuropsychiatric Institute Act. Its objective is to amend the Public Health Service Act to provide for research relating to psychiatric disorders and to aid in the development of more effective methods of prevention, diagnosis and treatment of such disorders. The term "psychiatric disorders" includes diseases of the nervous system that affect mental health.

To carry out these purposes the bill proposes the authorization of four important policies. These are the allotment of grants-in-aid to universities, hospitals, laboratories and other public or private institutions and to individuals for such research projects as are recommended by the newly established National Advisory Mental Health Council, the construction and equipment of buildings and facilities to be known as the National Institute of Mental Health, which is to be part of the National Institute of Health, the admission and treatment at the institute of voluntary patients as well as patients of St. Elizabeth's Hospital, in Washington, D. C., and the development of training and instruction in matters relating to the diagnosis, prevention and treatment of psychiatric disorders. Although nongovernmental institutions would play a large role in education and research, the National Institute of Mental Health would serve as a focal point for research, experimentation and advanced or specialized training, and as a clearing house for the collection and dissemination of information concerning advances in the prevention, diagnosis and treatment of psychiatric disorders.²

This program is to be administered by the Surgeon General of the United States Public Health Service at the federal level and by state mental-health authorities at the state level. The National Advisory Mental Health Council, consisting of the Surgeon General and six members, is created and is charged with the review and recommendation of research projects, the collection and publication of information on studies in the field of mental health and the recommendation of grants for training of personnel.

The bill proposes an initial appropriation of up to \$4,500,000 for the building and equipment of the new institution and of a total of \$11,000,000 for the current expenses of the program during the first year.

In December, 1945, the House committee reported favorably on the bill with the amendments.

There can be no doubt that this legislative proposal is a step in the right direction. One can only express the hope that it will be enacted and soon be followed by a bill for the improvement of facilities and services for persons with mental deviations. In

many parts of the country such a service program lags behind the present knowledge of mental deviations and the methods for their proper treatment.

NATIONAL INSTITUTE OF DENTAL RESEARCH BILL

The National Institute of Dental Research Bill (S 190), introduced by Senator Murray, is designed to provide for, foster and aid in co-ordinating research relating to dental diseases and conditions and to establish the National Institute of Dental Research. It authorizes federal grants-in-aid to the states for research in the prevention and control of dental diseases and conditions, as well as the establishment of a federal institute as part of the National Institute of Health, which will serve as a central research and training institution and a co-ordinating agency. Closely following the lines of other health bills, the measure vests the Surgeon General of the United States Public Health Service with administrative responsibility and creates the National Advisory Dental Research Council to review research projects, collect and publish pertinent information and review applications for grants-in-aid.

The initial appropriations for this program include up to \$1,000,000 for the building and equipment of the institute and \$730,000 for each fiscal year to cover the current expenses of the program.

Everyone who has carefully studied the many earlier surveys of mouth conditions and the recent findings made in connection with the Selective Service examinations is aware of the magnitude of the dental-health problem and will lend support to any proposal for intensive research. This purpose, however, is not served by the offer of several dissimilar proposals in different bills. There appears to be need for agreement on the policy to be pursued, as well as for concentration of legislative effort.

NATIONAL SCIENCE FOUNDATION BILL

The National Science Foundation Bill (S 1720), introduced by Senator Kilgore, is a compromise bill succeeding the earlier Kilgore Bill (S 1297) and the Magnuson Bill (S 1285). One of its objectives is to advance the national health and welfare, and its general policy is clearly stated in the following words: "Full development and application of the Nation's scientific and technical resources is essential for the national health and welfare."

Use of tax funds for the support of research by both governmental agencies and nongovernmental organizations is the core of the proposal. Of the total funds not less than 15 per cent are to be expended for research and development in health and medical sciences. These allocations are to supplement rather than supplant the functions or activities of other governmental agencies authorized to engage in scientific research and development. They are to be made for projects approved by the administrator and undertaken on behalf of the

National Science Foundation Freedom of research and publication is assured by the provision that every effort is to be made to eliminate restraints on the free expression of scientific views and to ensure full freedom in the exercise of creative talents, in the development of new ideas and in the method of research. Any person engaged in such research and development activities is not precluded from discussing, writing or publishing his own findings and conclusions.

In addition to research, undergraduate and postgraduate education would be supported by tax funds. The bill contemplates an authorization to award scholarships and fellowships to persons for scientific study or scientific work at nonprofit institutions of higher education or other institutions, selected by the recipient of such aid, for such periods as the administrator may determine, in the United States or in foreign countries. With this the door to medical education is opened to many qualified students lacking the necessary financial resources.

To administer this program, the creation of a special central agency, the National Science Foundation, is proposed. This agency has a divisional structure and includes eight divisions, one of which is the Division of Health and Medical Sciences. The Interdepartmental Committee on Science is to correlate and appraise research activities of all federal agencies engaged in or concerned with this field.

Full-time administration of the foundation is the guiding principle of organization. A full-time administrator is to be appointed by the President by and with the advice and consent of the Senate. There is to be a full-time deputy administrator, appointed by the President, and full-time divisional directors and staff members, all appointed by the administrator. The National Science Board of nine members is established to advise the administrator on all matters of major policy or program or budget, and divisional scientific committees of not less than five and not more than fifteen members will serve the divisions in an advisory capacity. The members of the board, the divisional committees and the staff of the foundation are to be chosen without regard to their political affiliations and solely on the basis of their demonstrated capacity to carry out the purposes of the foundation and their fitness to perform the duties of their office.

The Kilgore Bill expresses the best scientific thinking, is drawn in conformity with the wishes of those interested in the promotion of unhampered research and deserves enactment. It has been passed by the two Senate committees concerned.

RESEARCH PROVISIONS OF THE NATIONAL HEALTH BILL

The National Health Bill, or Wagner-Murray-Dingell Bill, in Title I includes research and the performance of demonstrations in the definition of public-health work, declares demonstrations to be part of the maternal and child health program and

the services for crippled children, and requires the United States Children's Bureau to make and aid in the financing of such studies, demonstrations, investigations and research as will promote the efficient administration and operation of this part of the bill.

Title II, which deals with prepaid personal health service benefits, contains the following important section:

For the purposes of encouraging and aiding the advancement and dissemination of knowledge and skill in providing benefits under this Act and in preventing illness, disability and premature death, the Surgeon General is hereby authorized and directed to administer grants-in-aid to nonprofit institutions and agencies engaging in research or in undergraduate or postgraduate professional education.

It is indeed gratifying to find so much emphasis placed on research, but it is disturbing to notice the absence of an over-all plan to correlate the various provisions scattered in many bills.

* * *

This presentation, intentionally limited to some of the major bills introduced in 1945, shows that there is a wave of enthusiasm for health legislation. Porter R. Lee³ once wrote "The crystallizing of enthusiasm into programs is a wholesome development. It betokens an awakened community alert to its social obligations, and an awakened community is a bulwark of progress. Moreover, concepts, ideals and enthusiasm are of little effect until they do crystallize into programs." We find ourselves in a situation that resembles what Voltaire called the "*embarras de richesse*" (the embarrassment of riches).

In deciding on the various legislative proposals, we are faced not so much with the problem of rejecting obviously inadequate measures as with the hard choice between good and better plans. Let us keep in mind that long-term strategy, rather than stop-gap tactics, assures ultimate victory in the fight against disease, defect, human suffering and poverty. The question to be answered may be formulated as follows: Do we want piecemeal legislation, with its inevitable result of fragmentary and unequal development, or comprehensive health legislation, with its promise of substantial achievements throughout the country? The issue is well stated in a recent report of the United States Public Health Service: "The Nation cannot afford to be content with less than a comprehensive program — a program to apply throughout the length and breadth of the land, in every community, all the knowledge we have for prevention of disease, the relief of suffering and the promotion of health."⁴

MEDICAL PROGRESS

NORMAL GROWTH AND DEVELOPMENT DURING ADOLESCENCE (Concluded)*

HAROLD C. STUART, M.D.†

BOSTON

ADOLESCENT CHANGES IN PHYSIOLOGIC FUNCTIONS
Basal Metabolism

There is of course an increase in the number of basal calories consumed per hour by the body as it increases in size year by year, and this is greater during pubescence than previously because the body size is increasing more rapidly. There is, however, less clear evidence regarding any fundamental increase in the basal metabolic rate associated with pubescence that is not explained on the basis of increased amount of active protoplasmic tissue.

In a comprehensive study of basal metabolism in girls, Talbot, Wilson and Worcester⁴⁵ in 1937 investigated the effects of pubescence on these rates. They concluded from a review of all data that an elevation of the heat production of girls tends to start at about ten years of age and reaches its maximum at the menarche, but that this rise is not a constant finding and that puberty per se cannot be considered the causative factor. They believed that there was sufficient evidence that the increased rate of growth in height during this period was the primary factor. Nylin⁴⁶ expressed the same opinion in 1935. Shock⁴⁷ has presented a curve for the basal heat production of girls in relation to the menarche, expressed as calories per square meter of surface area per hour. This shows a slight rise in the two and a half to three years before the menarche, an absence of change to the menarche and a continuing decline during the first three years thereafter. This period of rapid fall is more closely associated with the menarche than with any particular age. Webster, Harrington and Wright⁴⁸ report thorough longitudinal studies of basal metabolism in a few boys and girls over these years and discuss the changes in relation to growth and development. Johnston⁴⁹ ⁵⁰ made closely repeated determinations of metabolic rates in girls during the year of the menarche. He found them markedly unstable at this time, with a tendency to high rates just before the menarche and lower rates shortly after it.

Lewis and his associates⁵¹ ⁵² have conducted extensive longitudinal studies of basal metabolism in children up to fifteen years of age and have provided valuable tables of norms for sex and age. They failed to establish any absolute increase during

pubescence in the mean basal metabolism expressed as calories per square meter per hour. They point out, however, that during the ages of eleven to fifteen years in boys and ten to twelve years in girls, the rate of fall is greatly diminished in comparison with that in the preceding years, being only one quarter of the earlier rate in boys and one half of it in girls. They interpret this as indicating a relatively increased metabolism during pubescence. Talbot and his associates⁴⁵ considered the possibility that the enlargement of the thyroid gland that often occurs at this time might be responsible for an increased metabolic rate, but they concluded that the evidence does not point to any such relation. They found no trend toward an elevated pulse rate at this period that could account for an increased metabolic rate, but Shock has since reported a rise of ten points in the average pulse rate in girls during the pubescent period.

There is general agreement that following the menarche in girls and maximum growth in boys the basal oxygen consumption falls sharply during the first year and to a lesser amount in the next two to five years. Talbot et al. state that between the menarche and the age of fifteen and a half years in girls the rate falls about 5 per cent below the average trend. Shock compared the curves of absolute oxygen consumption for early maturing girls and boys with those for late maturing groups. The boys had a higher average rate than the girls on an age basis, but the curves for both groups showed the same steady postpubescent decline. They became more uniform when plotted against the menarcheal age for girls and the maximum growth age for boys than when plotted against chronological age.

There appears to be some disagreement on the question whether the basal metabolic rate is most advantageously expressed in terms of surface area, height or weight. Talbot⁵³, ⁵⁴ recommends that it be expressed in terms of urinary excretion of creatinine. His reason is that this excretion is a function of the amount of muscle in the body and that muscle is the principal active protoplasmic tissue. Since it is peculiarly difficult to interpret basal metabolic rates during adolescence because of the great normal variability and the many factors concerned in determining any given rate, it seems especially desirable to use several methods of expression and to consider the values obtained by each method in respect to appropriate norms. So far as possible the develop-

mental age should be taken into account as well as the chronological age. The various tables of values published in the references cited are especially useful for this purpose.

Although the evidence concerning the nutritional requirements during the adolescent years is not reviewed in this report, it is of interest to call attention to the changes in the caloric values of the diets consumed by adolescents during the years in which the basal consumption is changing in the manner described.

If one considers the basal calories in relation to total caloric intake at the beginning and at the end of pubescence, a suggestion is given of the differences between boys and girls at these periods in muscle mass, which primarily determines normal basal calories, and in physical activity, which is one of the major variables that contribute to the differences between basal and total calories. The tables presented by Lewis⁴ show that for girls of ten to eleven years of age the average caloric consumption per hour is 493, or 1183 a day. Wait and Roberts⁵⁵ estimate that at ten years the average total caloric intake of girls is 2100. Lewis's tables give values for average basal calories for boys of twelve to thirteen years as 53.5 an hour or 1284 a day, and the best estimate of total caloric intake for boys at twelve years appears to be 2600 calories. Thus, at the age of onset of pubescence, when body size is much the same in both sexes, the basal caloric consumption of boys is about 10 per cent greater than that of girls, whereas the total calories taken are nearly 25 per cent greater. The same data for the end of pubescence are as follows. Between the ages of thirteen and fourteen the basal caloric consumption of girls is given as 56.5 an hour or 1356 a day, and the total calories consumed at thirteen years as approximately 2600. The corresponding figures for boys aged fifteen to sixteen are 64.0 an hour or 1536 a day, and the total calories at fifteen years in the neighborhood of 3500. Thus, at a comparable stage of late pubescence, but with boys on the average considerably larger than girls, the basal caloric consumption is nearly 15 per cent greater in boys than in girls and the total calories consumption is about 25 per cent greater.

Wait and Roberts found that the largest increase in the average total caloric intake occurred in the thirteenth year, during which the average girl is accomplishing her maximum growth. These authors call attention to the great variability both in the number of calories consumed by children of the same age and in the day-to-day intakes of the same children. When one considers that caloric needs are principally determined by basal needs, together with the amount of muscular activity, and that basal needs are largely influenced by size and particularly amount of muscle, these age and sex differences are quite understandable. They should all be taken into account both in interpreting basal metabolic

rates and in considering dietary needs during the adolescent years.

Calcium and Nitrogen Retention

Johnston⁵⁶ has published several studies of calcium and nitrogen retention during the adolescent years under various circumstances. In this connection he has brought out several interesting relations between glandular activity, appetite and growth. High retention of calcium and nitrogen tend to occur just before the menarche and a sharp fall takes place immediately thereafter. This rise and this fall, however, sometimes precede and sometimes follow the first period. Estrogenic substances administered to normal girls at puberty depress calcium balances and occasionally nitrogen balances as well. Johnston concluded from studies of normal and abnormal thyroid function and thyroid therapy during adolescence that optimum retentions of calcium and nitrogen occur when metabolic rates are elevated within the normal range but not excessively stimulated.

Other Physiologic Activities

Most of the physiologic processes that are unassociated with sexual development or with the basic endocrine activities related to sexuality have become well stabilized before adolescence, and relatively small changes take place in them during the latter years of growth.

Shock⁴⁷ has obtained physiologic data based on studies of 50 girls every six months from the ages of twelve to eighteen years, with the age at the menarche known, and has plotted them on a menarcheal-age basis. These include pulse rates, systolic and diastolic blood pressures and pulse pressures, and basal respiratory volumes. His studies show that on the average among girls the systolic blood pressure rises steadily during the three years preceding the menarche — from 97 to 107 mm — and remains at about the latter level during the ensuing five years. The diastolic pressure shows no constant change during either period. Hence, there is a net increase in pulse pressure during the premenstrual period, with little change thereafter. The average pulse rate shows a rise from 63 three years before the menarche to 73 one year before it and a slight drop to 70 at the menarche. The pulse falls further to 65 in the first three years and to 60 in the next two after the menarche. The basal respiratory volume expressed as liters per minute rises sharply in the two or three years before menarche — from 3.2 to 4.7 liters — and remains constant thereafter, but expressed as liters per square meter of body surface area per minute it presents an early rise followed by a gradual fall. Thus, in all these measurements except diastolic pressure there appears to be an increase during pubescence in girls.

In another publication, Shock⁵⁷ presents norms for 50 adolescent boys and 50 adolescent girls on a

MEDICAL PROGRESS

NORMAL GROWTH AND DEVELOPMENT DURING ADOLESCENCE (Concluded)*

HAROLD C. STUART, M.D.†

BOSTON

ADOLESCENT CHANGES IN PHYSIOLOGIC FUNCTIONS *Basal Metabolism*

There is of course an increase in the number of basal calories consumed per hour by the body as it increases in size year by year, and this is greater during pubescence than previously because the body size is increasing more rapidly. There is, however, less clear evidence regarding any fundamental increase in the basal metabolic rate associated with pubescence that is not explained on the basis of increased amount of active protoplasmic tissue.

In a comprehensive study of basal metabolism in girls, Talbot, Wilson and Worcester⁴⁵ in 1937 investigated the effects of pubescence on these rates. They concluded from a review of all data that an elevation of the heat production of girls tends to start at about ten years of age and reaches its maximum at the menarche, but that this rise is not a constant finding and that puberty per se cannot be considered the causative factor. They believed that there was sufficient evidence that the increased rate of growth in height during this period was the primary factor. Nylm⁴⁶ expressed the same opinion in 1935. Shock⁴⁷ has presented a curve for the basal heat production of girls in relation to the menarche, expressed as calories per square meter of surface area per hour. This shows a slight rise in the two and a half to three years before the menarche, an absence of change to the menarche and a continuing decline during the first three years thereafter. This period of rapid fall is more closely associated with the menarche than with any particular age. Webster, Harrington and Wright⁴⁸ report thorough longitudinal studies of basal metabolism in a few boys and girls over these years and discuss the changes in relation to growth and development. Johnston⁴⁹ ⁵⁰ made closely repeated determinations of metabolic rates in girls during the year of the menarche. He found them markedly unstable at this time, with a tendency to high rates just before the menarche and lower rates shortly after it.

Lewis and his associates⁵¹ ⁵² have conducted extensive longitudinal studies of basal metabolism in children up to fifteen years of age and have provided valuable tables of norms for sex and age. They failed to establish any absolute increase during

pubescence in the mean basal metabolism expressed as calories per square meter per hour. They point out, however, that during the ages of eleven to fifteen years in boys and ten to twelve years in girls, the rate of fall is greatly diminished in comparison with that in the preceding years, being only one quarter of the earlier rate in boys and one half of it in girls. They interpret this as indicating a relatively increased metabolism during pubescence. Talbot and his associates⁴⁵ considered the possibility that the enlargement of the thyroid gland that often occurs at this time might be responsible for an increased metabolic rate, but they concluded that the evidence does not point to any such relation. They found no trend toward an elevated pulse rate at this period that could account for an increased metabolic rate, but Shock has since reported a rise of ten points in the average pulse rate in girls during the pubescent period.

There is general agreement that following the menarche in girls and maximum growth in boys the basal oxygen consumption falls sharply during the first year and to a lesser amount in the next two to five years. Talbot et al. state that between the menarche and the age of fifteen and a half years in girls the rate falls about 5 per cent below the average trend. Shock compared the curves of absolute oxygen consumption for early maturing girls and boys with those for late maturing groups. The boys had a higher average rate than the girls on an age basis, but the curves for both groups showed the same steady postpubescent decline. They became more uniform when plotted against the menarcheal age for girls and the maximum growth age for boys than when plotted against chronological age.

There appears to be some disagreement on the question whether the basal metabolic rate is most advantageously expressed in terms of surface area, height or weight. Talbot⁵³ ⁵⁴ recommends that it be expressed in terms of urinary excretion of creatinine. His reason is that this excretion is a function of the amount of muscle in the body and that muscle is the principal active protoplasmic tissue. Since it is particularly difficult to interpret basal metabolic rates during adolescence because of the great normal variability and the many factors concerned in determining any given rate, it seems especially desirable to use several methods of expression and to consider the values obtained by each method in respect to appropriate norms. So far as possible the develop-

ence growth does not occur and that with excess excretion general uniform overgrowth takes place.

The initial stages of sexual differentiation, especially of the growth of the gonads, are believed to result from an increased production of the gonadotropic and adrenocorticotrophic hormones, the former probably acting directly and the latter indirectly by stimulating the androgenic zones of the adrenal glands. Lack of these hormones during the prepubescent period results in some degree or type of hypogonadal state. An excess of these hormones prior to puberty produces manifestations of precocious sexual development, with or without early reproductive capacity. Some of these deviations from the normal may also occur as a result of abnormal levels of secretion of the specific part of the adrenals referred to, owing to disease in these glands.

The gonadotropic hormone is excreted in the urine, and repeated quantitative determinations have been made throughout adolescence on twenty-four-hour specimens of urine in several groups of normal boys and girls. The reports of Nathanson, Towne and Aub⁶⁶ on studies at Harvard and of Dorfman, Greulich and Solomon⁶⁷ on studies at Yale are of particular interest. These indicate that the gonadotropic hormones — measured by Nathanson as the follicle-stimulating hormone (F S H) and by Dorfman as gonadotropin — do not appear in measurable quantities in girls until eleven years of age or in boys until thirteen years. Excretion of the hormones increases rapidly in amount after their first appearance, and this increase coincides with the dramatic increase in the hormones from the peripheral sex glands. Nathanson et al point out that the secretion of the follicle-stimulating hormones probably precedes that of the gonads, but that the methods available for their assay at the time of the study were not sufficiently precise for their presence to be recognized in their initial small concentrations.

Estrogens are the female sex hormones, which are probably produced both by the adrenal glands and by the ovaries, and androgens are the male sex hormones, measured as the 17-ketosteroids and produced both by the adrenal glands and by the testes. According to Nathanson, Towne and Aub, estrogens and androgens are both present in both sexes in fairly constant but negligible amounts between three and seven years of age. The amounts of these excreted in the urine increase moderately and to a like degree in girls and boys between seven and nine years, the 17-ketosteroids on the average being slightly higher in boys and the estrogens in girls. Between nine and eleven years the 17-ketosteroid excretion increases more rapidly in boys and the estrogen excretion in girls, but individual differences are extremely wide. During the twelfth year on the average, but sometimes earlier, a cyclic variation in output of estrogens by girls becomes obvious, with wide differences between the peaks and minimum

values in single cycles. The average values continue to rise in girls after eleven years, whereas the output of estrogens by boys remains relatively constant. During this same period boys excrete increasing quantities of the 17-ketosteroids, but the difference between the sexes in the excretion of androgens is not nearly so marked as that of estrogens becomes.

Nathanson and his co-workers conclude that there is a primary stimulation of the gonads and adrenal glands that causes a steady — noncyclic — increase in both androgens and estrogens in both sexes. The high values and cyclic excretions of estrogens occurring in girls result from a superimposed stimulation — presumably of the ovaries by the pituitary gland after the former have matured sufficiently to excrete quantitatively. Similarly, the high urinary values of the 17-ketosteroids occurring later in boys are thought to be the result of an added excretion from the maturing testes. Thus, the gonadotropic hormones of the pituitary apparently first stimulate the adrenal cortex to increased but steady excretion of 17-ketosteroids and estrogens. At the same time they stimulate the growth and maturation of the testes and ovaries and later stimulate these organs to hormonal activity. This causes a higher but relatively steady excretion of androgens by boys and a much higher and cyclic excretion of estrogens by girls, thereby leading to the ultimate marked differences between the sexes in the amounts of these hormones found in the urine.

Talbot et al⁶⁸ have also studied the excretion of 17-ketosteroids in relation to age and have emphasized that the amounts recoverable from the urine before ten years are negligible. They also found that little sex difference is discernible until fifteen years of age and that the output by boys increases up to eighteen years of age at least. It should be pointed out, however, that it has not been demonstrated that the gonads themselves secrete any hormones that affect the development of the sex organs or sex characteristics prior to the pubescent period. Moore⁶⁹ has reviewed the evidence relating to the gonads during embryonic and prepubescent life, and concludes that they do not secrete hormones that affect sex-organ development during these periods. In considering the relations between the levels of these excretions and the physical changes associated with adolescence, the following observations have been made. First, the simple linear elevations in these excretions have progressed for several years, probably three or four, before the first clinical signs of sexual differentiation appear. This covers the period that I have referred to as prepubescence. Second, the sudden sharp rise of estrogens in girls, which precedes by a short interval the development of cyclic variations, is closely associated with the early physical changes of pubescence and rapid growth of the ovaries and may be said to mark the beginning of the pubescent period. Cyclic variations in excretion of estrogens are apparently taking place

chronological-age basis from eleven and a half years to seventeen and a half years. The principal sex difference appears to be that after fourteen years of age the average systolic pressure and pulse pressure are considerably higher for boys than for girls. Graham⁵⁸ also presents figures for blood pressures based on repeated determinations in 3580 children, from which he secured modal values as well as variability values with age. Variability tended to increase with age but was more pronounced among girls between ten and thirteen years old than among boys of the same age range. The tables presented by Richey⁵⁹ giving blood-pressure values by age also serve as useful reference standards. Graham reviews the relations between blood-pressure levels, body size and physical maturation.

The changes in blood cytology have been studied by Osgood and Baker⁶⁰ up to thirteen years and by Mugrage and Andresen⁶¹ for the same period. These changes are not of sufficient magnitude to deserve description here, but the tables presented by these authors serve as valuable reference standards for the early years of adolescence. The values given for thirteen years appear to be near the adult values for women, although the hemoglobin and red-cell values are somewhat below those for men.

THE ENDOCRINE GLANDS

It has been recognized for many years that the processes of growth and maturation are influenced by, if not completely under the control of, hormones secreted by several of the endocrine glands. Extensive research during recent years, based largely on animal experimentation but supplemented by studies of grossly abnormal children and the clinical use of endocrine products, have done much to clarify understanding of the mechanisms involved. More recently the development of methods for determining the amounts of certain hormones excreted in the urine of normal as well as of abnormal children has especially helped to confirm certain hypotheses regarding the endocrine activities associated with growth and maturation during adolescence.

It is not within the scope of this report to review the extensive literature in this field. The reviews prepared by Aldrich⁶²⁻⁶⁴ several years ago are still useful for background. There is now in press a clinical review by Talbot and Sobel⁶⁵ that considers the more recent evidence concerning the endocrine factor, as well as other factors that determine growth. A few recent studies of the urinary excretions of certain hormones by normal children year by year during adolescence are so pertinent to the subject of this report that the findings will be reviewed.

The glands known to be involved in the developmental changes occurring during adolescence are the thyroid, the pituitary, the adrenals and the gonads. The thyroid gland is included because of its known relation to basal metabolism and to osseous development and because there is a tendency for

it to hypertrophy during adolescence. The participation of the thyroid in the complex glandular interrelations that constitute the mechanism controlling adolescent development does not, however, appear to be a major or direct one. It has been pointed out that the differences in basal oxygen consumption, which should reflect changes in thyroid activity, are primarily related to body size and muscle mass and that age differences in basal metabolic rates corrected on this basis are not consistently different to any significant degree. The determination of blood iodine levels as an index of thyroid activity appears to have value principally in dealing with diseased persons. In some series of reported cases considerable enlargement of the thyroid gland has been found to occur during pubescence in a large proportion of cases, but this does not appear to be uniformly true in all localities. Pryor⁶⁶ examined 74 girls in San Francisco at the time of onset of the menses and reported slight enlargement in 16, moderate enlargement in 47 and definite lateral enlargement of both lobes in 10, with only 1 girl showing no enlargement. I have, however, found enlargement in only a small proportion of the children studied in Boston, and in these cases it was of slight degree.

The relation of the thyroid gland to epiphyseal growth and the steps leading to union with diaphyses is well known. The rate of maturation in these locations is unquestionably influenced by the drug thyroid, and normal thyroid function is necessary for normal osseous development. The pituitary and possibly other glands play a part in regulating this process, and its continuance to the point of union of epiphyses with diaphyses ultimately leads to the cessation of growth. It does not, however, appear that any sudden change in thyroid activity is responsible for the termination of growth or for any of the specific changes associated with pubescence or post-pubescence.

The glands that are of special interest in this connection are the pituitary, the adrenals, the ovaries and the testes. The interactions of the hormones elaborated by these glands appear to be responsible, in large measure at least, for the progressive stages of adolescent development that have been described. The anterior lobe of the pituitary gland is known to elaborate several hormones, among which the growth hormone, the gonadotropic hormone—of which there are two or more fractions, follicle-stimulating and gonadotropic—and the adrenocorticotrophic hormone have been most thoroughly studied. It appears that an increased secretion of the growth hormone is primarily responsible for the general acceleration of the rate of growth of the body as a whole and that a decrease in this secretion, probably brought about by action of the gonads, accounts in part for the sudden deceleration in growth. This conclusion is based primarily on studies showing that in its ab-

some deviations in physical status or growth progress. A carefully taken family history often makes it appear that these are intrinsic in nature, but this conclusion cannot be accepted until a careful investigation of environmental factors has been carried out and a serious effort has been made to correct unfavorable influences. It is also unsafe to compare two racial groups of children and to conclude that any differences found to exist between them are racial in origin. Several recent studies offer strongly suggestive evidence that dietary habits or factors associated with socioeconomic circumstances may have more to do with the differences found to exist between racial groups than has the factor of race itself.

Some writers have stressed the differences in size and build and rate of maturation between groups of children living under different climatic conditions, but here again one must be cautious in accepting climatic factors as responsible unless racial differences on the one hand and socioeconomic differences on the other have been taken into account. Mills⁷⁴ has brought together considerable evidence in support of a climatic effect. This evidence deals not only with the average age of the menarche and with the rates of growth of children in different climates but also with these differences in animals reared in different atmospheric conditions. Mills states that in regions of depressing moist heat, both growth and the menarche are delayed and the final adult form is slender and small, whereas growth and pubescent development are most accelerated and the most robust body forms are seen in the stimulating, stormy temperate regions. He has obtained exactly similar differences in laboratory animals, where ease or difficulty in loss of body heat was the experimental variable.

Michelson⁷⁵ has attempted to determine whether differences in the age at the menarche between Whites and Negroes are attributable to race or socioeconomic circumstances. He studied twelve separate population groups and showed that Negro girls born and living in the West Indies reached the menarche on the average at 13.99 years, those in the southern part of the United States did so at 13.68 years, those in New York State at 12.94 years, and a small well-to-do group in New York State at 12.85 years. White girls born and living in New York State reached the menarche on the average at 12.86 years. Although the average age at the menarche for all Negroes is considerably later than that for Whites, this breakdown into groups makes it seem extremely doubtful that race per se is primarily responsible.

Other students have reported differences in menarcheal ages for different socioeconomic groups, with very late occurrence among girls in the less favored groups. Larger samples and better selected groups must be studied, however, before the influence of socioeconomic factors can be considered to have been established. The same may be said

of the recent reports from Europe to the effect that girls are now menstruating about one year later than was previously usual in countries subjected to severe dietary restrictions and other socioeconomic stresses during the recent war. The accumulating evidence suggests strongly, however, that prolonged undernutrition, especially in calories and protein, may retard maturation as well as physical growth. This is not surprising in view of the fact that chronic starvation leads to amenorrhea in women and to loss of the secondary sex characteristics in both men and women.

Meredith⁷⁶⁻⁷⁸ has reviewed the evidence concerning the effects of race, region and socioeconomic factors on the height and weight of children. Using the Harvard Growth Study data, he compared children born and living in Massachusetts of North European ancestry with those of Italian ancestry in respect to stature. The former exceeded the latter at all ages from seven to seventeen years in both sexes. The increments of gain year by year were not significantly different during this period, however, the racial difference having been established by seven years, the earliest age studied.

In another study based on more than 60 samples of boys between the ages of nine and fourteen years representing differences in race, class, time and region, Meredith found that boys in the United States of various ethnic groups, otherwise roughly comparable, differ in average height between groups up to a maximum of 5 cm, that white boys residing in different parts of the United States vary little in average height and weight, and that white boys of the professional and major managerial classes are taller and heavier than those of the unskilled and semiskilled classes, the differences not exceeding 3 per cent for stature and 6 per cent for weight.

Meredith's most interesting findings have to do with a striking secular trend over the last fifty years. His analysis of the measurements obtained in Toronto school children in 1892, 1923 and 1939 are of particular interest. The typical Toronto boy aged thirteen to fourteen years was taller in 1939 than was the boy of 1892 by nearly 9 cm, and the typical boy of 1923 was about midway between. The differences at all ages were in the same direction, although of less marked degree. Meredith also finds that boys in the United States today, both White and Negro, are 6 to 8 per cent taller and 12 to 15 per cent heavier than were boys half a century ago. In general, secular differences in the United States covering the last half-century are twice as large as any of the other differences considered, whereas geographical differences are the smallest of all. Several studies of the heights of college boys in recent years and of their fathers while in college, and similarly of college girls and their mothers a generation ago, have revealed a considerable increase indicative of a secular trend. The causes for these evidences of increasing size with time call for further

during much of the pubescent period in girls — that is, for a year or more prior to the menarche. It is therefore consistent with these occurrences to postulate that the ovarian follicular hormone is necessary before cyclic excretions can begin, and that under this stimulation uterine development must have progressed sufficiently before the menstrual cycle can be completed. The menarche thus follows a period of several years of gonadal endocrine development. Third, the first sharp increase in the excretion of 17-ketosteroids in boys is associated with rapid growth of the adrenal glands and precedes that of rapid growth of the testes. A further increase is associated with rapid growth of the testes and appearance of the secondary sex characteristics. This association of events lends support to the presumption that the former is primarily of adrenal origin and the second of testicular origin. Lastly, the shift from neuter configuration to greater differentiation in physical characteristics accompanies the changes in the levels of these hormonal excretions. Nathanson and his associates⁷⁰ have reported a correlation of 0.8 between excretion of 17-ketosteroids and that of urinary creatinine in both boys and girls. Since the latter is a function of muscle mass, androgenic excretions are presumably closely correlated with amount of muscle. The greater development of muscles in boys over girls actually occurs during the years when the excretion of androgens is becoming markedly greater in boys than in girls. Both Nathanson and Dorfman have found that the individual variability in the excretion levels of these hormones is to some extent correlated with the physical development of the subjects.

With several hormones being produced and interacting on each other, the variations in the timing, character and magnitude of adolescent growth and sexual differentiation are readily understandable. Furthermore, with the production of both male and female sex hormones by both sexes, and in different amounts between individuals, various degrees of femininity in boys and masculinity in girls are to be expected. In considering many of the variables in both sexes, as, for example, late development in girls with broad shoulders, narrow hips and considerable body hair as contrasted with early development in boys with broad hips, narrow shoulders and sparse body hair, differences in the balance of the sex hormones from the usual occurrence may be assumed. Nathanson and Aub cite an example of striking change from obvious feminine identification in 2 boys toward masculinity associated with a rise in the androgen-estrogen ratio from estrogen excess to androgen preponderance. Further studies are required to demonstrate the relations between individual variability in hormonal excretions and growth and maturation.

FACTORS CONTRIBUTING TO GROUP DIFFERENCES IN GROWTH AND DEVELOPMENT OF NORMAL ADOLESCENTS

A better understanding of the normal physical and physiologic changes of adolescence, and particularly of the variability in their manifestations, which is consistent with good health and satisfactory ultimate development, would undoubtedly lead to more rational management of many of the so-called "problems of adolescence." It is not suggested that these problems do not require attention, but rather that the recognition that they are in many cases essentially physiologic would result in more conservative therapy and in greater emphasis on hygienic living. Frank⁷¹ has called attention to some of the implications of what is known about growth and development during the adolescent years in respect to the policy and program of care for adolescent from a health standpoint. Shorr⁷² approaches such endocrine problems from this point of view and has discussed the management of the usual ones. He takes the position that most of these can best be handled by a sane program of physical and mental hygiene, planned from the point of view that they are in the main expressions of physiologic variations.

It is now fully established that hormones elaborated by the endocrine glands are primarily responsible for the events that have been shown to occur in connection with the progress of a child toward maturity. Nevertheless, it is of interest to consider what conditions may lead to variations in hormonal activities and hence to differences between individuals or groups during this period. Since this report is concerned with normal occurrences, the effects of congenital abnormalities, defects, accident and disease will not be considered.

Racial and familial traits have long been recognized as important predeterminers of group as well as of individual characteristics. The extensive literature bearing on these hereditary factors can not be reviewed here, but it is clear that any effect brought about by environmental factors can operate only within the limitations imposed by the genetically determined qualities and potentialities of the initial germ plasm. Boas⁷³ devotes much attention to the parts played by heredity and environment in bringing about family and racial differences. He has found that certain traits, such as the form of the head and face, are much more strongly influenced by race or family pattern than are others like height and weight. From statistical analyses of extensive studies, however, he concludes that even facial characteristics are modified by changes in environment. Hence, it is unwise to assume that any physical attribute is entirely determined by heredity or cannot be modified by environment. In clinical practice it is important to recognize individual characteristics that are constitutional in character and that may impose physical limitations or lead to ex-

CASE 32221

PRESENTATION OF CASE

A fifty-three-year-old Navy veteran entered the hospital because of dysphagia.

The patient was apparently well until three years before admission, when his ship was torpedoed. Hereafter he became quite "nervous." Four months before entry, he noted during luncheon the sudden onset of inability to swallow. He continued to have similar attacks several times a month, but they occurred only during periods of nervous excitement. During an attack a piece of solid food would "get caught in the neck", it was usually vomited immediately, but occasionally it was swallowed. Once the first solid food had passed, the remainder of the meal followed fairly readily. He had little trouble with liquid or soft foods. One month before entry, the patient vomited some bloody material while waiting in the Out Patient Department. He was immediately admitted to the Massachusetts Eye and Ear Infirmary, where a barium swallow showed a questionable lesion of the lower end of the esophagus. A chest film was normal. An esophagoscopy showed injection of the mucosa and engorged vessels near the cardia, and the operator gained the impression that a hard mass was pushing the esophagus forward, thus narrowing the lumen, no ulceration was seen. A biopsy specimen from this region showed slight chronic inflammation and edema. Examination of the blood showed a red-cell count of 2,530,000, with 8.6 gm of hemoglobin, and a white-cell count of 5800, with 57 per cent neutrophils. He was then discharged to the Out Patient Department.

He did well at home, eating everything, including hard biscuits, and gaining a few pounds in weight. Two weeks before entry he was again seen at the Eye and Ear Infirmary for a repeat esophagoscopy. The findings were identical with the previous ones. A No 22 bougie passed the lower third of the esophagus with difficulty. The biopsy specimen showed acanthosis, slight chronic inflammation and edema. A barium swallow was reported as indicating some esophageal obstruction. A gastro-

intestinal series revealed a constantly deformed duodenal cap, but no ulcer crater was demonstrated. Examination of the blood showed a red-cell count of 3,720,000, with 10.5 gm of hemoglobin, and a white-cell count of 6600.

Two days before entry, the patient was unable to swallow even milk "because of nervousness." Afterward he was able to eat a full meal. The patient stated that he lost 20 to 30 pounds in weight during the four months before admission. He gave no history of epigastric distress, intolerance to fatty foods, jaundice or melena.

Physical examination revealed a somewhat emaciated man who was in no acute distress. The heart was normal. A few crackling rales were heard at the bases of the lungs. The abdomen and extremities were negative.

The temperature, pulse, and respirations were normal. The blood pressure was 130 systolic, 78 diastolic.

Examination of the blood revealed a red-cell count of 4,000,000, with 70 per cent hemoglobin, and a white-cell count of 7900 with 57 per cent neutrophils. The total proteins were 6.3 gm per 100 cc, and the chloride 104 milliequiv per liter. The urine was normal. The stools were brown, and one of two specimens gave a positive guaiac test.

X-ray examination of the chest showed no abnormality. Another gastrointestinal series revealed no difficulty in the act of swallowing. The esophagus showed some tubulation of the lower 2 or 3 cm and an apparent soft-tissue thickening just about the cardia. Small soft-tissue masses seemed to project into the gas bubble, and barium was seen to "squirt" from the cardia across the gas bubble. Fluoroscopically the stomach appeared normal, with the exception of considerable thickening of the gastric rugae. On the film, however, there was questionable rigidity on the cardiac side of the fundus. The duodenal cap was again constantly irregular and deformed, it also showed an irregular fleck in the center of the cap measuring about 0.5 cm in diameter. The upper small intestine was not remarkable.

Two additional esophagoscopy biopsies showed acute and chronic inflammation. On the fifteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR EARLE M CHAPMAN: May we see the x-ray films?

DR JAMES R LINGLEY: These films of the lower esophagus show the rigidity and irregularity that was referred to in the summary and, in addition, a suggestion of a mass above the cardia pressing on the gas bubble of the fundus. The same thing is seen in this film, a soft-tissue mass projecting into the fundus of the stomach. In this view, taken in the upright position, the barium seems to swerve across the base instead of passing along the lesser curvature.

study, but they are doubtless related to differences in the incidence of illnesses in early life, to dietary habits, to habits of activity and to other more obscure factors generally referred to as socio-economic

The physician dealing with a child who is under-size or otherwise underdeveloped cannot determine to what extent these features are due to heredity and to what extent to faulty diet or hygiene or to disease. If one or both of the child's parents show similar characteristics, the physician may be tempted to accept a genetic explanation as fully satisfactory without appreciating that in all probability environmental factors have played some part and possibly a dominant one. His assumption in itself tends to block further study and to keep him from devoting attention to diet and hygiene. It appears to be a more rational approach, and certainly one more in accord with recent findings, to assume that both hereditary and environmental factors are operative to some extent in all cases. Hence, heredity should never be accepted as the sole or even the principal factor in a given case until a thorough investigation has failed to reveal other retarding influences, or until correction of faulty environmental influences has been accomplished to the fullest possible extent.

Medical supervision of the care of infants and young children has unquestionably contributed greatly toward better health and development during these early years. This has been made possible by intensive study of the normal course of events as well as of the special problems at these ages. Medical supervision during the adolescent years can undoubtedly contribute much toward better health and more generally satisfactory development during this period also, and hence toward a higher standard of physical fitness at maturity. This progress, however, is dependent on further research and a better understanding of the normal course of events and the special problems of these years.

specimens, and both of them were negative, but I ought from the whole picture that the patient had carcinoma of the cardiac orifice and that he should be explored by the transthoracic route, with a cooperative diagnosis of carcinoma

DR. LINGLEY I also disagree with Dr Chapman wonder what type of benign tumor can involve the esophagus and the stomach By x-ray there is definite involvement of the esophagus

DR. CHAPMAN I got the impression in reading the description that a mass was pushing the esophagus aside

DR. LINGLEY That was by esophagoscopy

DR. CLAUDE E. WELCH Two or three of our resected stomachs every year show evidence of duodenal ulcer when the primary lesion is a cancer of the stomach

CLINICAL DIAGNOSIS

Carcinoma of the stomach

DR. CHAPMAN'S DIAGNOSES

Cardiospasm

Polypoid adenoma of stomach.

Gastritis

Duodenal ulcer

ANATOMICAL DIAGNOSIS

Carcinoma of cardia of stomach, with periesophageal extension

PATHOLOGICAL DISCUSSION

DR. MALLORY This patient was explored by the transthoracic route A gastrectomy was performed, the resected specimen including the lower portion of the esophagus A scirrhus carcinoma of the cardia was found This had invaded upward in the outer wall of the esophagus, narrowing it from external pressure without growing out into the mucosa of the esophagus at any point So it is natural that Dr Benedict's biopsy specimens did not show tumor They had not gone deep enough, and should not have gone deep enough, to reach this tumor in the outer layers of the esophageal wall

DR. CHAPMAN Is that not a rare location for a scirrhus type of carcinoma?

DR. MALLORY They are much less frequent in that area than in other parts of the stomach

CASE 32222

PRESENTATION OF CASE

First admission A fifty-five-year-old liquor dealer entered the hospital because of weakness and tarry stools

The patient was in apparent good health until one year before entry, when he had an episode of pain and weakness in the left lower quadrant of the abdomen X-ray films taken at that time showed no abnormality He recovered completely Five months before entry, on his return home after a hard day in his store, he suddenly felt "sick at his stomach" and fainted following urination Afterward he felt very weak and passed some tarry stools A local doctor called the next day and found a marked anemia Another gastrointestinal series was negative The patient gradually regained full strength but continued to pass occasional tarry stools Ten days before entry the patient had another episode of weakness followed by tarry stools mixed with gross blood The patient had suffered from gout for many years

Physical examination revealed a well developed man in no acute distress showing marked pallor of the skin and mucous membranes The lungs were clear A soft systolic murmur was heard at the apex There was some tenderness to deep palpation in the left lower quadrant Proctoscopic examination was negative

The temperature, pulse and respirations were normal The blood pressure was 120 systolic, 80 diastolic

The examination of the urine was negative The blood showed a red-cell count of 2,150,000, with a hemoglobin of 6.6 gm and a hematocrit of 20 The white-cell count was 6400, with a normal differential The nonprotein nitrogen was 40 mg per 100 cc, the serum protein 6.5 gm, and the uric acid 6.6 mg The prothrombin time was 21 seconds (normal, 18 to 20 seconds), the bleeding time 2.5 minutes, and the clotting time 10 minutes The blood Hinton reaction was negative A stool specimen gave a negative guaiac test A gastrointestinal series with hourly films showed the esophagus, stomach and small bowel to be normal A barium enema was also negative

The patient was given three blood transfusions of 500 cc each On the tenth hospital day an exploratory laparotomy and appendectomy were performed No cause of the gastrointestinal bleeding could be found He recovered uneventfully and was discharged on the nineteenth hospital day

Second admission (two months later). Despite the occasional passage of occult blood in the stools, the patient felt well until six days before his second admission, when he returned from a two-day hunting trip feeling "all in" After the evening meal he became nauseated but had no pain The nausea and weakness persisted until the day of admission, when the local doctor found the blood pressure to be 80 systolic, with the diastolic pressure unobtainable An enema on the previous day was said to have produced a grossly bloody stool He had not vomited at any time during his illness

as it normally does. The film of the chest shows a normal heart and lungs, but it suggests a mass in the region demonstrated in the gastrointestinal film. I think that the observation of an ulcer crater in the duodenum must have been that of the fluoroscopist. The films show deformity but no definite crater that I can make out.

DR CHAPMAN: It seems obvious to me that we are dealing here with evidence of a tumor of the stomach, and so it comes down to a question of type. Was it a benign tumor or a malignant tumor? If we paraphrase the history, briefly, we have a man of fifty-three who suddenly had difficulty in swallowing, vomited blood, had an anemia, had lost a good deal of weight, had guaiac-positive stools and had a mass in the fundus of the stomach, it is a temptation to make a diagnosis of malignant tumor, which would be a sound clinical diagnosis.

On analysis of some of the clinical features in this case, however, I rather favor the possibility that this lesion was some benign condition. So we have to think of the benign lesions that can produce this syndrome in a man of fifty-three. To begin with, we have the fact that he had been nervous and emotionally upset. He then had what sounds like a typical description of cardiospasm, because although at times he could swallow solids and fluids, at other times, after being emotionally upset, he could not even swallow liquids. Another strong clinical point is the absence of pain. Carcinoma usually produces pain, but we do know that about 10 per cent of such patients may be without pain, and in Osler's¹ original series of 160 patients with extensive carcinoma of the stomach, 20 had no pain. Another clinical point is the improvement in the anemia, which is unexplained. When the patient first came in he had a red-cell count of 2,500,000, but later, just before operation and I judge without transfusion, the count was 4,000,000, with a hemoglobin of 70 per cent. That is another point against a malignant lesion. The third clinical point against a malignant lesion is that the rugae were thickened and that a duodenal ulcer was present, a combination that is most unusual in a person with carcinoma higher up. The association of duodenal ulcer and cancer of the stomach is quite rare.

If it was a malignant lesion, what type could it be? In this region it should be the medullary type, a large cauliflower-like growth that invades all layers of the stomach and produces villous-like projections into the stomach. It can produce the picture that Dr Lingley has described, but this man was operated on and apparently did not come to autopsy, and I have a hunch that he is still alive. If it was a medullary carcinoma, he might have had metastases in the lungs, and yet there is no evidence of metastases in the chest films.

If it was a benign lesion, what type could it be? There are several types of benign tumors of the stomach. One is a bezoar, sometimes found in

nervous people. I cannot believe that a bezoar would do this, nor can I believe that this was one of the rare types of tumor, such as myxoma, fibroma, or a cystic tumor. One tumor that falls midway between the extremely malignant and benign forms is lymphoma. It is too bad that we do not have a complete blood picture, although I do not believe that a differential count would have substantiated a diagnosis of lymphoma.

There is one other type of benign tumor that this might be, that is, a so-called "polypoid adenoma," which is seen in older people in the presence of gastritis. In Winternitz's² case there were multiple tumors not only in the stomach but throughout the intestine, and also multiple skin tumors of the hemangioendothelioma type. I looked carefully to see whether skin tumors were described on physical examination, but none were reported.

The biopsy diagnosis of acanthosis is a puzzling point.

DR MALLORY: Leukoplakia might have been a better word to use — and a more familiar term.

DR CHAPMAN: The word acanthosis made me think of a rare skin condition known as acanthosis nigricans, which is often associated with cancer of the stomach, but the clinical record gives no indication of skin pigmentation, so that acanthosis nigricans is unlikely.

Finally, because of these four clinical points — the absence of pain, the improvement in the anemia, the presence of a duodenal ulcer and the existence of cardiospasm without proof of carcinoma from four esophagoscopies — I am going to say that this patient had a polypoid adenoma of the stomach.

I have one other comment to make. Here is another case in which the endoscopist and the roentgenologist have not been able to make a positive diagnosis. I think that that is chiefly because of the mechanical difficulties consequent to the location high in the fundus, where examination is difficult.

DR TRACY B. MALLORY: Dr Benedict, you esophagoscoped this patient. Let us hear your views.

DR. BENEDICT: I do not agree with Dr Chapman in two respects. First, he says that cancer of the stomach is usually a painful process. There is no pain whatever in many cases of cancer of the stomach. Second, I think that the x-ray interpretation was of great help in this case. Dr Lingley has just described a rigid terminal portion of the esophagus, with, I think he said, a mass infiltrating the fundus of the stomach. To my mind, that is fairly typical of carcinoma arising in the stomach and infiltrating the lower esophagus. I had made up my mind to that before Dr Mallory showed me the record.

I did an esophagoscopy on this man twice, and both times I met complete obstruction at the cardiac orifice. I then tried to pass the gastroscope, but it also met complete obstruction. When the gastroscope meets complete obstruction at the cardiac orifice it usually means cancer. I did get biopsy

This also does not rule out gastritis because we do not know when the gastroscopy was performed — how long after the hemorrhage, which he had seven days after admission. Gastritis may heal rapidly and not be demonstrable after a bleeding episode. I do not believe, however, that gastritis is the diagnosis because it is unlikely without any other symptoms and a negative gastroscopy.

We might consider such a rare condition as telangiectasia, a hereditary condition, which does occur in the stomach, but since it is associated with cutaneous and mouth lesions, which this patient did not have, I think that it can be discarded.

We come now to the hiatus hernia. A hiatus hernia may bleed, but it is generally a slow oozing. Massive bleeding does rarely occur and is usually associated with gastritis or ulceration in the mucosa of the hernia. Since there was no evidence of that by gastroscopy or esophagoscopy and since he had no other symptoms, I do not believe that that was the cause of the bleeding.

Did he have a tumor of the small intestine, which might easily have been missed by x-ray examination, such as a leiomyoma, an adenoma or a neurogenic tumor? That is a possibility but I doubt that it was the cause.

Could he have had a tumor of the stomach that was missed by all these examinations? If he had a small carcinoma, it would be extremely unlikely that he had no other symptoms except bleeding. Massive hemorrhage from carcinoma is quite unusual, particularly in a person who has had repeated hemorrhages over a long period of time.

Did he have a benign tumor of the stomach, such as a polyp or leiomyoma? Either of these tumors may be small and may ulcerate and bleed, particularly a leiomyoma, and may be missed by x-ray examination.

In view of such completely negative findings I can do no more than guess, but I shall suggest a diagnosis that is most consistent with the symptomatology given, even though it is a rare condition. I think that the symptomatology of the patient fits in best with a leiomyoma of the stomach. This tumor is often associated with repeated massive hemorrhages without any other symptoms. It must have been a small one to have been missed by x-ray examination and exploration, but for the reasons given the other usual causes of bleeding are unlikely.

DR. TRACY B. MALLORY: Dr. Benedict, have you any comment?

DR. EDWARD B. BENEDICT: I thought that on a statistical basis this was fairly likely to be a duodenal ulcer in spite of the negative examination and the negative exploratory laparotomy. Even if one sees the stomach and duodenum at operation one cannot always see the lesion. I believed that he should have a resection on the basis that he was bleeding from the duodenum.

CLINICAL DIAGNOSIS

Gastrointestinal hemorrhage (ulcer?)

DR. HALSTED'S DIAGNOSES

Leiomyoma of stomach

Gout

ANATOMICAL DIAGNOSES

Gastric ulcer, acute

Gastritis, acute

PATHOLOGICAL DISCUSSION

DR. ARTHUR W. ALLEN: I explored this man two or three months before his ultimate operation. At that time I went over his entire gastrointestinal tract as carefully as I could, having in mind particularly that this might have been a small-bowel lesion. Early tumors of the small intestines are extremely difficult to pick up in the x-ray examination, even with the so-called "small-bowel enema." The exploration was absolutely negative. My own reaction about it was that if he had had a duodenal ulcer that had caused three bouts of hemorrhage we should have found some indication of scarring, even if we could not feel a crater. Since the duodenum never looks normal after there has been an ulcer that has bled massively, one always has some lead that the disease is in that region. But this duodenum was absolutely normal. There was nothing abnormal that I could palpate throughout the length of the small bowel. I was not so happy about palpation of the colon because the large bowel was not completely empty at the time of exploration. But even when the colon is empty, it is sometimes difficult to palpate a polyp. On the other hand, satisfactory barium enemas had been performed, and the roentgenologists can diagnose polyps by that method quite accurately. So I did nothing except the exploration and appendectomy, being still in doubt about the source of his bleeding.

We have a certain number of patients who bleed massively from the gastrointestinal tract in whom we cannot find the cause or source of hemorrhage. Of course the majority of them have a definite lesion that can be so demonstrated by our various examinations that we are quite sure of the diagnosis. Then there is a small group that have lesions that we suspect as being the source of bleeding, the chief one of these being diverticulosis, although we are never quite certain about that.

The reason that this man was operated on the second time is that we thought he was going to bleed to death if we did not do something about it. We had information for the first time after gastroscopy, which caused him to have blood in the vomitus, indicating that the source of the bleeding was high. Based on the experience of just one other case that we had here a few years ago, in which all examinations except that for gastritis

Physical examination revealed a pale, anemic and weak-appearing man with no acute complaints. There was minimal deep tenderness over the cecal region. Proctoscopy was again negative.

The temperature, pulse and respirations were negative. The blood pressure was 102 systolic, 80 diastolic.

Examination of the blood revealed a hemoglobin of 5.5 gm. The white-cell count was 5000, with 73 per cent neutrophils. The urine was negative. Three stool specimens gave strongly positive guaiac tests.

A gastrointestinal series and a barium enema were entirely negative except for a hiatus hernia of the stomach measuring 2.5 cm in diameter. On the morning of the seventh hospital day the patient vomited four times following the administration of 0.5 mg of colchicine. The vomitus had the appearance of coffee grounds.

The patient received two 500-cc blood transfusions. Gastroscopy and esophagoscopy were entirely negative. On the twentieth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. JAMES A. HALSTED The tenderness to deep palpation in the abdomen may be explained by the fact that this man had been operated on for appendicitis two months before admission and might be expected to have tenderness in that region.

Do you care to show the x-ray films, Dr. Lingley?

DR. JAMES R. LINGLEY They are negative.

DR. HALSTED He did have a small hiatus hernia, but I imagine that it was chiefly seen by fluoroscopy.

DR. LINGLEY That is correct, the films do not add anything.

DR. HALSTED This middle-aged man was in good health except for gout, until he suddenly had pain in the left lower quadrant and weakness. We do not know whether this was caused by a gastrointestinal hemorrhage, nor do we know what x-ray films were taken, but in view of the subsequent history we can assume that this was the first of four massive hemorrhages that he had during the course of a year. He was without any other gastrointestinal symptoms. He had four gastrointestinal x-ray examinations, all of which were negative except for a small hiatus demonstrated at the last. He also had a negative exploratory operation two months before the last admission, two negative proctoscopies and a negative gastroscopy and esophagoscopy. There is thus almost nothing to go on except symptomatology.

The physical and laboratory examinations reveal nothing other than signs of marked anemia and an elevated uric acid, which would be expected with gout. I do not know how to evaluate the pain in the left lower quadrant or the tenderness in this region noted at the first admission, but in view of the negative barium enema, negative proctoscopy

and negative laparotomy I am inclined to discount it as unimportant. One thinks of diverticulitis, but such a lesion does not bleed.

There is nothing to suggest that a primary blood disorder caused the hemorrhages. We can dismiss gout as playing a role in the picture except to comment on the fact that he probably had an acute attack, although the record does not state it, at the time of the second admission because he was given colchicine. This resulted in, or rather was followed by, vomiting of coffee-grounds material. One tablet of colchicine is unlikely to produce vomiting. Acute attacks of gout occur typically in a gouty person following such upsetting episodes as an operation, a trip, a hemorrhage and an infection. So I am not surprised that he had attacks after these hemorrhages.

The first problem is to try to place the location of the hemorrhages. The stools were described as tarry on several occasions but gross blood was noted on two occasions. Blood from the colon may be dark but is rarely dark enough to be termed "tarry." Tarry stools usually mean that the bleeding is coming from the stomach or small intestine. The fact that he had grossly bloody stools also does not necessarily suggest a large-bowel lesion, since bright red blood may appear in the stools after a hemorrhage from the stomach provided intestinal motility is fast enough. He only vomited once, and the vomitus was described as coffee-grounds in appearance, which is strong evidence that the blood came from the stomach or duodenum. The possibility of multiple lesions arises. Polyposis, both of the colon and stomach, is a rare entity. In the presence of negative proctoscopic, gastroscopic and x-ray examinations it may be excluded. All in all, the evidence points to the bleeding from the stomach or small intestine.

Could this have been due to an extragastric cause, such as cirrhosis or Banti's disease? The patient was a liquor dealer, but that does not mean that he drank excessively or at all. The two recorded white-cell counts show a slight leukopenia, but in the absence of esophageal varices, which ought to be demonstrable by x-ray examination or esophagoscopy, and of splenomegaly and in the presence of a negative laparotomy I think that we can exclude cirrhosis and Banti's disease.

Duodenal ulcer is the most frequent cause of hemorrhage. It may occur without other symptoms, but if one that bleeds four times in a year, it should produce digestive symptoms. X-ray examination may be negative, although again it is unlikely to be negative four times. I do not believe that he would have been subjected to operation twice for ulcer if it was not demonstrable.

Gastritis often causes severe hemorrhage. X-ray examination is a poor method of diagnosing gastritis, so that four negative examinations do not rule it out. There was one negative gastroscopy

This also does not rule out gastritis because we do not know when the gastroscopy was performed — how long after the hemorrhage, which he had seven days after admission. Gastritis may heal rapidly and not be demonstrable after a bleeding episode. I do not believe, however, that gastritis is the diagnosis because it is unlikely without any other symptoms and a negative gastroscopy.

We might consider such a rare condition as telangiectasia, a hereditary condition, which does occur in the stomach, but since it is associated with cutaneous and mouth lesions, which this patient did not have, I think that it can be discarded.

We come now to the hiatus hernia. A hiatus hernia may bleed, but it is generally a slow oozing. Massive bleeding does rarely occur and is usually associated with gastritis or ulceration in the mucosa of the hernia. Since there was no evidence of that by gastroscopy or esophagoscopy and since he had no other symptoms, I do not believe that that was the cause of the bleeding.

Did he have a tumor of the small intestine, which might easily have been missed by x-ray examination, such as a leiomyoma, an adenoma or a neurogenic tumor? That is a possibility but I doubt that it was the cause.

Could he have had a tumor of the stomach that was missed by all these examinations? If he had a small carcinoma, it would be extremely unlikely that he had no other symptoms except bleeding. Massive hemorrhage from carcinoma is quite unusual, particularly in a person who has had repeated hemorrhages over a long period of time.

Did he have a benign tumor of the stomach, such as a polyp or leiomyoma? Either of these tumors may be small and may ulcerate and bleed, particularly a leiomyoma, and may be missed by x-ray examination.

In view of such completely negative findings I can do no more than guess, but I shall suggest a diagnosis that is most consistent with the symptomatology given, even though it is a rare condition. I think that the symptomatology of the patient fits in best with a leiomyoma of the stomach. This tumor is often associated with repeated massive hemorrhages without any other symptoms. It must have been a small one to have been missed by x-ray examination and exploration, but for the reasons given the other usual causes of bleeding are unlikely.

DR. TRACY B. MALLORY: Dr. Benedict, have you any comment?

DR. EDWARD B. BENEDICT: I thought that on a statistical basis this was fairly likely to be a duodenal ulcer in spite of the negative examination and the negative exploratory laparotomy. Even if one sees the stomach and duodenum at operation one cannot always see the lesion. I believed that he should have a resection on the basis that he was bleeding from the duodenum.

CLINICAL DIAGNOSIS

Gastrointestinal hemorrhage (ulcer?)

DR. HALSTED'S DIAGNOSES

Leiomyoma of stomach
Gout

ANATOMICAL DIAGNOSES

Gastric ulcer, acute
Gastritis, acute

PATHOLOGICAL DISCUSSION

DR. ARTHUR W. ALLEN: I explored this man two or three months before his ultimate operation. At that time I went over his entire gastrointestinal tract as carefully as I could, having in mind particularly that this might have been a small-bowel lesion. Early tumors of the small intestines are extremely difficult to pick up in the x-ray examination, even with the so-called "small-bowel enema." The exploration was absolutely negative. My own reaction about it was that if he had had a duodenal ulcer that had caused three bouts of hemorrhage we should have found some indication of scarring, even if we could not feel a crater. Since the duodenum never looks normal after there has been an ulcer that has bled massively, one always has some lead that the disease is in that region. But this duodenum was absolutely normal. There was nothing abnormal that I could palpate throughout the length of the small bowel. I was not so happy about palpation of the colon because the large bowel was not completely empty at the time of exploration. But even when the colon is empty, it is sometimes difficult to palpate a polyp. On the other hand, satisfactory barium enemas had been performed, and the roentgenologists can diagnose polyps by that method quite accurately. So I did nothing except the exploration and appendectomy, being still in doubt about the source of his bleeding.

We have a certain number of patients who bleed massively from the gastrointestinal tract in whom we cannot find the cause or source of hemorrhage. Of course the majority of them have a definite lesion that can be so demonstrated by our various examinations that we are quite sure of the diagnosis. Then there is a small group that have lesions that we suspect as being the source of bleeding, the chief one of these being diverticulosis, although we are never quite certain about that.

The reason that this man was operated on the second time is that we thought he was going to bleed to death if we did not do something about it. We had information for the first time after gastroscopy, which caused him to have blood in the vomitus, indicating that the source of the bleeding was high. Based on the experience of just one other case that we had here a few years ago, in which all examinations except that for gastritis

Physical examination revealed a pale, anemic and weak-appearing man with no acute complaints. There was minimal deep tenderness over the cecal region. Proctoscopy was again negative.

The temperature, pulse and respirations were negative. The blood pressure was 102 systolic, 80 diastolic.

Examination of the blood revealed a hemoglobin of 5.5 gm. The white-cell count was 5000, with 73 per cent neutrophils. The urine was negative. Three stool specimens gave strongly positive guaiac tests.

A gastrointestinal series and a barium enema were entirely negative except for a hiatus hernia of the stomach measuring 2.5 cm in diameter. On the morning of the seventh hospital day the patient vomited four times following the administration of 0.5 mg of colchicine. The vomitus had the appearance of coffee grounds.

The patient received two 500-cc blood transfusions. Gastroscopy and esophagoscopy were entirely negative. On the twentieth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. JAMES A. HALSTED The tenderness to deep palpation in the abdomen may be explained by the fact that this man had been operated on for appendicitis two months before admission and might be expected to have tenderness in that region.

Do you care to show the x-ray films, Dr. Lingley?

DR. JAMES R. LINGLEY They are negative.

DR. HALSTED He did have a small hiatus hernia, but I imagine that it was chiefly seen by fluoroscopy.

DR. LINGLEY That is correct, the films do not add anything.

DR. HALSTED This middle-aged man was in good health except for gout, until he suddenly had pain in the left lower quadrant and weakness. We do not know whether this was caused by a gastrointestinal hemorrhage, nor do we know what x-ray films were taken, but in view of the subsequent history we can assume that this was the first of four massive hemorrhages that he had during the course of a year. He was without any other gastrointestinal symptoms. He had four gastrointestinal x-ray examinations, all of which were negative except for a small hiatus demonstrated at the last. He also had a negative exploratory operation two months before the last admission, two negative proctoscopies and a negative gastroscopy and esophagoscopy. There is thus almost nothing to go on except symptomatology.

The physical and laboratory examinations reveal nothing other than signs of marked anemia and an elevated uric acid, which would be expected with gout. I do not know how to evaluate the pain in the left lower quadrant or the tenderness in this region noted at the first admission, but in view of the negative barium enema, negative proctoscopy

and negative laparotomy I am inclined to discount it as unimportant. One thinks of diverticulitis, but such a lesion does not bleed.

There is nothing to suggest that a primary blood disorder caused the hemorrhages. We can dismiss gout as playing a role in the picture except to comment on the fact that he probably had an acute attack, although the record does not state it, at the time of the second admission because he was given colchicine. This resulted in, or rather was followed by, vomiting of coffee-grounds material. One tablet of colchicine is unlikely to produce vomiting. Acute attacks of gout occur typically in a gouty person following such upsetting episodes as an operation, a trip, a hemorrhage and an infection. So I am not surprised that he had attacks after these hemorrhages.

The first problem is to try to place the location of the hemorrhages. The stools were described as tarry on several occasions but gross blood was noted on two occasions. Blood from the colon may be dark but is rarely dark enough to be termed "tarry." Tarry stools usually mean that the bleeding is coming from the stomach or small intestine. The fact that he had grossly bloody stools also does not necessarily suggest a large-bowel lesion, since bright red blood may appear in the stools after a hemorrhage from the stomach provided intestinal motility is fast enough. He only vomited once, and the vomitus was described as coffee-grounds in appearance, which is strong evidence that the blood came from the stomach or duodenum. The possibility of multiple lesions arises. Polyposis, both of the colon and stomach, is a rare entity. In the presence of negative proctoscopic, gastroscopic and x-ray examinations it may be excluded. All in all, the evidence points to the bleeding from the stomach or small intestine.

Could this have been due to an extragastric cause, such as cirrhosis or Banti's disease? The patient was a liquor dealer, but that does not mean that he drank excessively or at all. The two recorded white-cell counts show a slight leukopenia, but in the absence of esophageal varices, which ought to be demonstrable by x-ray examination or esophagoscopy, and of splenomegaly and in the presence of a negative laparotomy I think that we can exclude cirrhosis and Banti's disease.

Duodenal ulcer is the most frequent cause of hemorrhage. It may occur without other symptoms, but if one that bleeds four times in a year, it should produce digestive symptoms. X-ray examination may be negative, although again it is unlikely to be negative four times. I do not believe that he would have been subjected to operation twice for ulcer if it was not demonstrable.

Gastritis often causes severe hemorrhage. X-ray examination is a poor method of diagnosing gastritis, so that four negative examinations do not rule it out. There was one negative gastroscopy

GAMMA GLOBULIN IN ACUTE HEPATITIS

IN THE October 4, 1945, issue of the *Journal*, the Massachusetts Department of Public Health announced the initiation of a program for the provision of blood and blood derivatives without cost to the citizens of Massachusetts. Among the blood derivatives that it hopes to provide is gamma globulin, which is prepared in such a manner as to contain in a concentrated form most of the antibodies that are normally found in human plasma. A number of studies by workers in different localities have been made in collaboration with Dr. Edwin J. Cohn and his associates in attempts to determine the prophylactic and curative value of gamma globulin in various infections. The results of several

such studies with respect to infectious hepatitis, formerly called "catarrhal jaundice," have already become available.

Stokes and Neefe¹ tested the prophylactic value of intramuscular injections of gamma globulin during an epidemic of infectious hepatitis in a summer camp for boys and girls. There were 331 children who had had no signs of disease when they began their study, and 53 of these were injected with gamma globulin, using an arbitrary dose of 0.15 cc per pound of body weight. Among those who received these injections, only 3 developed jaundice, but 8 additional children developed symptoms and laboratory evidence of hepatitis without overt jaundice. The icterus in the 3 cases was visible only in the scleras and not in the skin. Of the 278 children who did not receive globulin injections, 125 developed jaundice and 60 had evidence of hepatitis without jaundice. Thus, the total incidence of infection among the globulin recipients was 21 per cent, as compared with 67 per cent among the controls, a difference that is statistically significant. The average duration of icterus was about five days in the injected cases, and more than fourteen days in the control cases. Furthermore, the onset of hepatitis in the 11 patients who received gamma globulin occurred in every case during the first ten days following injection, whereas cases continued to appear among the controls for thirty-two days.

On the basis of this report, field studies on the prevention of hepatitis were conducted during an outbreak of this disease in a bombardment group based in the Mediterranean Theater of Operations during the fall and winter of 1944-1945.² The dose of gamma globulin chosen for this study was 10 cc, which was found to be the largest amount that could be injected without affecting the full-duty status of the men. Globulin was given to members of two squadrons and to a headquarters group, whereas those belonging to two other squadrons served as controls. Each of the squadrons had about 500 men, and all were quartered on the same field. Among the injected squadrons there occurred 3 cases of hepatitis with jaundice. Two of these cases occurred in persons who, for some reason or other, had not received the globulin injections. The third developed jaundice only of the scleras, and this began

were negative, we decided on subtotal gastrectomy. The first man, who was about the same age as the one under discussion today, had repeated hemorrhages and came back every three or four months exsanguinated. We finally did a subtotal gastrectomy on the basis of gastritis and found a lesion that was similar to the one discovered in today's case, which Dr. Mallory will describe.

DR. CLAUDE E. WELCH: The second operation was done after the decision had been made that we could not stand idly by, it was a matter of getting the patient into shape and doing, let us say, a blind subtotal gastric resection. The only important findings at operation were a few adhesions in the lesser omental sac, just behind the pylorus. Everything else was so negative that I thought Dr. Castleman should come to the operating room himself to be sure that we did not make any holes in the specimen.

DR. MALLORY: Dr. Castleman, will you tell us what you found?

DR. BENJAMIN CASTLEMAN: In the central portion of the stomach there was a small but definite superficial ulceration surrounded by a smaller and even more superficial erosion. There was no evidence at that time that the patient was still bleeding. As soon as I told Dr. Welch that I had found something he was delighted. He was afraid that the stomach would prove to be normal. The fact that we did find an erosion and a superficial ulceration satisfied him.

DR. MALLORY: The sections from the stomach showed a moderately severe gastritis well down in the pyloric area, where Dr. Benedict might not have been able to see it. In this area there was a very shallow erosion. One could just barely call it an ulcer, still it was quite active, with beginning healing at the margins. It is reasonable to say that that was the cause of the hemorrhage.

among battle casualties who had received transfusions of blood or plasma. Reference is also made to an experimental study that indicated that one preparation of gamma globulin had no neutralizing antibodies for one causative agent of serum hepatitis. The exact basis for the discrepancies has not yet been clarified. Thus, the prophylactic value of gamma globulin in the prevention of homologous serum jaundice remains uncertain.

Gamma globulin apparently has a definite place in the prophylaxis of infectious or epidemic hepatitis, that is, so-called "catarrhal jaundice." It is hoped that the Massachusetts program will receive enthusiastic support so that provision of gamma globulin for that purpose and for its use in other conditions in which it has proved effective will be possible. It should be borne in mind, however, that gamma globulin is not effective in modifying infectious hepatitis if given after symptoms have appeared and that at the present time its effectiveness in the prevention of homologous serum jaundice is not definitely proved.

MOTORCADE

THE most contumacious lover of living horseflesh must admit, after the passage of these fifty-odd years, that the automobile has come to stay. As the horse was to the cowboy, the circuit rider and the doctor of yesterday, so is the automobile today to the doctor, the salesman, the baker and the candlestick maker, multiplied a million times. The automobile is here in our outmoded town and city streets, we cannot ignore it, we cannot make it disappear by banning its parking or, if it is parked, by plastering it with tickets. It is to these millions a vital part of their bread-winning capacity, the very officer who makes the

stream of traffic halt at his command, succeeding where King Canute failed, or who occupies his time chalking the tires of potential overtime parkers, mounts his own chariot, his duty done, and drives away like Jehu the son of Jehoshaphat, or Mr Toad of Toad Hall. His hunting over he joins the exodus, immune, perhaps, from becoming one of the hunted.

It cannot be doubted that many of our citizens, commonly respected and accepted as decent members of society, legally married and the parents of small children, still have two sides to their characters — the Dr. Jekyll side, using their reputations as a sort of guarantee of irreproachable conduct, and the Mr. Hyde side, the latter manifesting itself when they are behind the wheels of moving automobiles. There is a hypnosis to swift vehicular travel that affects us all somewhat as it did the republican hero of *The Wind in the Willows*. It sets us on edge, it removes our sense of propriety and puts us in open conflict with all our fellows, even if it does not turn us into the scoundrels that the law, afoot or awheel, seems to consider all human beings awheel to be. All scoundrels, it is true, may at times drive motor cars, it does not follow that all drivers of motor vehicles are to be considered scoundrels until proved otherwise.

The physician, parenthetically, setting himself aside from other individuals and classes of men, although not above them, feels that there is a particular urgency about his use of the automobile, that to serve the public best he should be in a position to travel in his car with reasonable dispatch to minister to his patients, to visit his hospital or to reach his office, and to leave his car in legal, if not in physical, safety when he has arrived at any of these destinations.

Up to the present time the efforts of our traffic authorities, although zealous, appear to the conscientious driver to have been at times somewhat shortsighted. They have been designed primarily to speed up traffic flow with only secondary thought being given to the terminals and way stations at which that traffic must stop. Insufficient consideration is given to the facts that every driver is theoretically on some legitimate errand — the term "pleasure car" being now an outdated misnomer — and that to discharge his mission he must bring his

9 days after the injection. In the same period, 25 cases of hepatitis with jaundice occurred in the control squadrons. Previous to the time of the globulin injections, there had been 95 cases in the injected groups and 116 cases in the control groups.

A second study was undertaken in three groups of ground forces among which an epidemic of hepatitis had already started. Injections of 10 cc of gamma globulin were given to varying proportions of the strengths of these three groups — 40 per cent of one, 10 per cent of another and 25 per cent of the third. The groups consisted of 1089, 9101 and 1868 men, and they were followed for twelve, seven and five weeks, respectively, after the injections. A total of 9 cases of jaundice developed in the injected persons, an incidence of 0.5 per cent, as compared with 335 cases, or an incidence of 3.3 per cent, among the controls.

Havens and Paul³ also conducted a study on the prevention of infectious hepatitis during an epidemic in a Catholic home for children in New Haven, Connecticut. Doses ranging from 5 to 10 cc of gamma globulin were used, depending on the weight, the average being 0.08 cc per pound. Gamma globulin was given to 97 children, whereas 155 served as controls. Jaundice occurred in 2 of the inoculated children, and in 36 of the controls. There were 6 additional cases of hepatitis without jaundice in the protected group, and 17 among the controls. Thus, 8 per cent of the inoculated group came down with the disease, as compared with 34 per cent of the controls, and the incidence of cases of overt jaundice was more than ten times as frequent among the latter.

All these results indicate quite definitely that gamma globulin given to susceptible persons after exposure to or during the incubation period of infectious (epidemic) hepatitis usually prevents the disease, and that the disease is attenuated in most of those who become infected after inoculation. The passive immunity seems to last at least six or eight weeks.

Studies with gamma globulin in measles had suggested that it was of value in lessening the severity and in shortening the course of that disease if given soon after the onset of symptoms. In view of the long illness and convalescence in cases of infectious

hepatitis, it seemed worth while to determine whether gamma globulin had a similar attenuating effect in this disease. A study of this aspect was made during an outbreak of infectious hepatitis in the air forces in the Mediterranean Theater of Operations.⁴ Two hundred and seventy-eight patients admitted to the hospital with a tentative diagnosis of infectious hepatitis were studied. Gamma globulin was given intramuscularly in doses of 0.3 cc per pound of body weight to alternate patients. No significant difference in the severity or duration of jaundice or in the duration of the positive methylene blue test in the urine was observed in the two groups of cases. This study suggests that there is no attenuating effect of gamma globulin when given in these doses early in the course of infectious hepatitis.

Additional studies have been undertaken to determine whether gamma globulin also serves to prevent so-called "homologous serum jaundice." One such study was undertaken in a large general Army hospital in continental United States after 100 cases of jaundice had been observed among battle casualties who had received transfusions of whole blood or plasma.⁵ Casualties who had been wounded for less than four months and had received injections of various blood products but had not developed symptoms of hepatitis were chosen for this study. Alternate cases were given 10 cc of globulin on admission to the hospital, and this was repeated after one month. There were 384 cases in each group, and hepatitis with jaundice developed in 2.9 per cent of the globulin recipients, as compared with 11.5 per cent of the controls. In more than half the cases that occurred in the globulin recipients, the onset of symptoms of hepatitis occurred less than a week after globulin had been given. By contrast, more than three quarters of the cases that occurred among the controls began more than one week after admission. The results of this study suggest that the early administration of serum globulin was effective in preventing hepatitis in these cases. In an addendum to this report, however, mention is made of a similar study conducted at another large general Army hospital. In that study a single injection of globulin was used, and it seemed to have no effect on the incidence of homologous serum jaundice.

among battle casualties who had received transfusions of blood or plasma. Reference is also made to an experimental study that indicated that one preparation of gamma globulin had no neutralizing antibodies for one causative agent of serum hepatitis. The exact basis for the discrepancies has not yet been clarified. Thus, the prophylactic value of gamma globulin in the prevention of homologous serum jaundice remains uncertain.

Gamma globulin apparently has a definite place in the prophylaxis of infectious or epidemic hepatitis, that is, so-called "catarrhal jaundice." It is hoped that the Massachusetts program will receive enthusiastic support so that provision of gamma globulin for that purpose and for its use in other conditions in which it has proved effective will be possible. It should be borne in mind, however, that gamma globulin is not effective in modifying infectious hepatitis if given after symptoms have appeared and that at the present time its effectiveness in the prevention of homologous serum jaundice is not definitely proved.

MOTORCADE

THE most contumacious lover of living horseflesh must admit, after the passage of these fifty-odd years, that the automobile has come to stay. As the horse was to the cowboy, the circuit rider and the doctor of yesterday, so is the automobile today to the doctor, the salesman, the baker and the candlestick maker, multiplied a million times. The automobile is here in our outmoded town and city streets, we cannot ignore it, we cannot make it disappear by banning its parking or, if it is parked, by plastering it with tickets.

It is to these millions a vital part of their bread-winning capacity, the very officer who makes the

stream of traffic halt at his command, succeeding where King Canute failed, or who occupies his time chalking the tires of potential overtime parkers, mounts his own chariot, his duty done, and drives away like Jehu the son of Jehoshaphat, or Mr. Toad of Toad Hall. His hunting over he joins the exodus, immune, perhaps, from becoming one of the hunted.

It cannot be doubted that many of our citizens, commonly respected and accepted as decent members of society, legally married and the parents of small children, still have two sides to their characters — the Dr. Jekyll side, using their reputations as a sort of guarantee of irreproachable conduct, and the Mr. Hyde side, the latter manifesting itself when they are behind the wheels of moving automobiles. There is a hypnosis to swift vehicular travel that affects us all somewhat as it did the reptilian hero of *The Wind in the Willows*. It sets us on edge, it removes our sense of propriety and puts us in open conflict with all our fellows, even if it does not turn us into the scoundrels that the law, afoot or awheel, seems to consider all human beings awheel to be. All scoundrels, it is true, may at times drive motor cars, it does not follow that all drivers of motor vehicles are to be considered scoundrels until proved otherwise.

The physician, parenthetically, setting himself aside from other individuals and classes of men, although not above them, feels that there is a particular urgency about his use of the automobile, that to serve the public best he should be in a position to travel in his car with reasonable dispatch to minister to his patients, to visit his hospital or to reach his office, and to leave his car in legal, if not in physical, safety when he has arrived at any of these destinations.

Up to the present time the efforts of our traffic authorities, although zealous, appear to the conscientious driver to have been at times somewhat shortsighted. They have been designed primarily to speed up traffic flow with only secondary thought being given to the terminals and way stations at which that traffic must stop. Insufficient consideration is given to the facts that every driver is theoretically on some legitimate errand — the term "pleasure car" being now an outdated misnomer — and that to discharge his mission he must bring his

space-occupying transport somewhere to a halt, and there leave it for a period of time

To solve urban traffic problems — and for Boston the proposed garage under the Common would be only a partial answer — convenient scattered terminals must be furnished in a suitable ratio to the volume of traffic. Levees along a river to confine and hasten the flow of water do not constitute effective flood control. What must be provided are extra basins into which the flood waters can be diverted and allowed to settle. Similar areas for automobiles are more important for what appears to be our immediate mechanical future than are wide sidewalks, grassy malls or extra traffic officers with even louder whistles and more pieces of chalk

MASSACHUSETTS MEDICAL SOCIETY

RESOLUTION CONCERNING REVIEW LECTURE COURSE

The following resolution was unanimously adopted by those physicians attending the last session of the Review Lecture Course on May 15

RESOLVED that we, the physicians who have attended the Review Lecture Course for former medical officers and practitioners, presented by the Massachusetts Medical Society and the Department of Public Health, Commonwealth of Massachusetts, do hereby express our thanks and deep appreciation to the officers of the Massachusetts Medical Society, the officials of the Massachusetts Department of Public Health, the members of the various committees concerned, the chairmen, the lecturers and all others who so ably participated in planning and carrying through to a most successful conclusion the excellent program that was made available to us

This program not only met the requirements of those recently returned from active service but also those of the busy practitioners who have been unable to attend many medical meetings during the war years

DEATHS

ATWATER — James B. Atwater, M.D., of Westfield, died May 3. He was in his eighty-eighth year.

Dr. Atwater received his degree from the New York University Medical College in 1882. For thirty-seven years he was chief of staff at Noble Hospital, and since his retirement in 1934 chief-emeritus of that institution. He was a member of the American College of Surgeons, the American Academy of Medicine of New York, the New England Association of Railroad Surgeons and the Springfield Academy of Medicine, and a fellow of the American Medical Association.

Two sons, a sister, two grandsons and a granddaughter survive.

AYER — Thomas H. Ayer, M.D., of Westboro, died May 16. He was in his eighty-first year.

Dr. Ayer received his degree from the Bowdoin Medical School in 1893. He was a fellow of the American Medical Association. He retired in 1934.

EVANS — Miner H. A. Evans, M.D., of Wellesley Hills, died May 5. He was in his sixty-sixth year.

Dr. Evans received his degree from Harvard Medical School in 1902. He became assistant physician at the Danvers State Hospital and later became associated with the Adams Nervine Asylum. He established a private practice in Roxbury in 1906 and was also a member of the staffs of the neurologic services of the Boston Dispensary and the Carney Hospital. Later, he became associated with the Dorchester Free Dispensary, the Boston Psychopathic Hospital and the Boston City Hospital. At the time of his death, he was consulting physician in neurology and psychiatry at the Quincy City Hospital and visiting physician in neurology at the Boston City Hospital. He graduated in 1915 from the Boston University Law School and was later admitted to the Massachusetts and the United States bars, having been a consultant in many criminal trials. He was a member of the American Psychiatric Association, New England Society of Psychiatry and Neurology, Massachusetts Society of Psychiatry and Boston Society of Psychiatry and Neurology and a fellow of the American Medical Association.

His widow and two daughters survive.

CORRESPONDENCE

LOCAL INJECTION OF PENICILLIN

To the Editor: The following observations are offered in regard to the article "The Regional Injection of Penicillin in Local Infections," by Rose and Hurwitz in the February 28 issue of the *Journal*.

Injections of penicillin in saline are ordinarily painful. Given by the method described, in which the authors recommend "injecting slowly ahead of the needle, and progressing toward the center of infection," the injections may be severely painful, even if one avoids inserting the needle into the inflammatory area.

In my experience, this pain can be minimized by inserting the injection needle through a small skin wheal of 1 per cent procaine, thrusting the needle into the depth desired and then making the injection of penicillin as the needle is withdrawn. In our hands, this method has been effective in the treatment of large furuncles without incision. I have not added procaine to the penicillin solution itself. According to Hirsh and Dowling (*Am J M Sc* 210 435, 1945), however, small amounts of procaine would have no detrimental effect on the action of the penicillin.

HEALTH BILLS PENDING IN CONGRESS*

Part Four

FRANZ GOLDMANN, M D †

NEW HAVEN, CONNECTICUT

JULIAN HUXLEY once wrote, "To speculate without facts is to attempt to enter a house of which one has not the key." The desire to avoid speculation and obtain factual information on pending health legislation seems to be strong, judging from the fact that some of the bills are on the best-seller list of the Superintendent of Documents in Washington.

Important organizations, representing large groups of the population, have officially endorsed the major legislative proposals now in Congress. Many people from all walks of life favor government action in the whole field of health service, on the ground that protection of the right to health care is a fundamental function of any society aspiring to a genuine and rational economy of human resources and values.

ATTITUDE OF THE MEDICAL PROFESSION

In general, the medical profession supports the hospital survey and construction program embodied in the Hill-Burton Bill, the expansion and improvement of general public-health, maternal and child health services proposed in Title I of the National Health Bill, disability insurance as recommended in the Wagner-Murray-Dingell Bill of May, 1945, and federal aid for medical research and education as proposed in the National Science Foundation Bill, the Mental Health Bill, the National Health Bill and other pertinent measures.

But the physicians are not unanimous in their opinions on pending health legislation. A few insist that they are against any plan, and resent any encroachment on what they believe to be their own territory. Others prefer to pass responsibility to the economists by maintaining that if the standards of economic independence of the poor and the indigent are raised, the problem of medicine will take

care of itself. Still others doubt that any plan can be a success so long as certain evils are permitted to persist. A physician recently wrote to Senator Pepper, "As long as the United States is a place of easy divorce, quick-lunch counters and horn-tooting automobile drivers, and as long as the Smiths try to keep up with the Joneses, this will be a land of constipation, stomach ulcers, coronary thrombosis and emotional instability, and I don't think any 'plan' is going to help a great deal."¹

Many are willing to accept government participation in the organization of medical care, provided that it is confined to service for the control of communicable diseases, care of the mentally sick and defective and programs for the needy and special groups, such as the veterans. Here and there voices of doubt can be heard questioning the wisdom of supporting the legislative proposals officially endorsed by organized medicine. Some writers point out that the Hill-Burton Bill leaves the door ajar for serious federal interference in local affairs. Some physicians fear that the Kilgore Bill would restrict the traditional freedom of scientific research by bringing politics into science.

What is of paramount significance is the unqualified opposition of the American Medical Association to compulsory health insurance, as proposed in the National Health Bill, and to a system of tax-supported medical care, as recommended in the Maternal and Child Welfare Bill. This attitude on the part of physicians is not universal. Two organizations of physicians, composed of members of the American Medical Association, have repeatedly gone on record in favor of compulsory health insurance. Early in 1946, the Committee on Medicine and the Changing Order of the New York Academy of Medicine stated its belief thus: "It may be desirable to conduct careful experiments at state and local levels with compulsory government insurance, so that we may have in the near future comparative experience with the relative values of voluntary and compulsory procedure."²

*This is the last of a series of four lectures on medical sociology given at Harvard Medical School during February and March, 1946. They were sponsored by the Department of Preventive Medicine and were primarily intended for third-year students.

†Associate clinical professor of public health, Yale University School of Medicine.

Much of the opposition to legislative proposals dealing with medical care is due to misinformation concerning the contents of the bills, unfavorable personal experiences with some program, fear of a revolutionary change in the traditional pattern of practicing medicine and unfamiliarity of physicians with the history of organized care of the sick. As John Locke once wrote, "New opinions are always suspected and usually opposed, without any other reason but because they are not already common."

In the center of the debate at present is the method of compulsory health insurance. At the risk of laboring the obvious, it must be stated that health insurance by law is organized self-help financed by money that the self-supporting people are asked to save for the purpose of paying for their own care. What is changed by such legislation is the method of raising funds for the support of professional and institutional services. Instead of paying if and when service is received and in proportion to the amount of service rendered, people are required to pay in advance small average amounts, in return for which they are entitled to any or all of the services available under the program. What is not changed by such legislation is the institution of private practice of medicine, dentistry and related professions, the institution of voluntary hospitals and the institution of voluntary health agencies. Being, as it is, a method of organizing payment for medical care, compulsory health insurance is neither a cure-all for social evils nor the gateway to the millennium.

There is nothing new about compulsory health insurance. It was adopted in this country as early as 1798, when the Act for the Relief of Sick and Disabled Seamen was passed. At that time this method of raising money was considered the most equitable one, as Mr. Williamson stated in the House of Representatives. At present compulsory health-insurance programs are in operation in some thirty countries in Europe, Asia, South America and Australia, and in Mexico. The potentialities and limitations of this method are known to every student of the subject, and experience is more than ample. If Congress should pass the pertinent measure, it would be possible to avoid, rather than to repeat, the many mistakes made in sixty years of trial and error. With the knowledge now available a plan can be designed that provides not only for the organization of payment but also for the establishment and maintenance of high standards of service throughout the country.

The arguments advanced against the compulsory-health-insurance title of the Wagner-Murray-Dingell Bill and against the Maternal and Child Welfare Bill are many and varied. Those based on misinformation need no discussion here. Of the others, two deserve special consideration—the assertion that socialized medicine is just around the corner, and the assumption that so-called "political

medicine" is about to be imposed on the American people.

SOCIALIZED MEDICINE

The term "socialization," and with it the term "socialized medicine," have been used in a shifting sense. The latter term actually has two quite dissimilar meanings. It may denote a system of medical care organized on the basis of the political and economic theory of socialism. Such a program calls for public ownership of all facilities for medical care, with the abolition of nongovernmental ownership of institutions, for the employment of all professional personnel by public agencies, with the discarding of private practice, and for public administration of all health services, with elimination of nongovernment agencies. None of the bills under consideration propose the adoption of such a program.

The term "socialized medicine" may also mean a program of medical care organized for the purpose of adapting medicine to social needs and uses, with no regard to socialist doctrines and methods. In this sense, American medicine has been socialized for some time and to a considerable extent. At present, about three fourths of all beds in registered hospitals and probably about half of all clinics are in institutions built from tax funds and operated by local, state and federal agencies. Many and diverse socioeconomic groups are entitled to medical care at the taxpayers' expense. They include several million recipients of public assistance and many millions of self-supporting people, such as the veterans, merchant seamen, Indians and Eskimos, wives and infants of enlisted men, the medically needy and certain employees of the federal government. In the fiscal year 1943-1944, the total expenditures of tax funds for medical care of civilians amounted to at least \$900,000,000. The workmen's compensation acts, which are in force in all the states but one, require medical care to be furnished to those covered, and in 1943-1944 \$140,000,000 was spent for this purpose.

Taxation and insurance by law have been the two methods employed to finance medical-care programs in the past, and these are the very methods proposed for the organization of payment for medical care in the future.

The bugaboo of socialized medicine can frighten only those who mistake "social" for "socialistic." It is about time to stop fighting over terminology and to concentrate time and effort on the intricate task of working out the method of action that best promises to achieve the ends desired by all.

POLITICAL MEDICINE

The second argument, which expresses a fear of political interference, if not political control, derives from the fact that in the past the selection of patients, the appointment of personnel, etc.

methods of institutional administration were in some instances influenced by the desire to make friends, gain votes and reward favorite sons (and daughters) for faithful political activities. But the picture is not so black as some persons would have one believe. There are many examples of good government in the field of health administration. What is more significant, a growing number of agencies and communities have been making constant and determined efforts to clean their own houses and to eliminate the taint of political medicine.

The danger of political manipulation of a nationwide system of medical care cannot be lightly dismissed, but it can be averted. Let us now resolve to establish the tradition of good government in every community. If we fail in this task, we shall be admitting our unwillingness to exercise one of our precious constitutional rights and duties.

The major bills now under consideration have one element in common: they require all appointments to administrative positions to be made strictly on the basis of merit. Enactment of these measures will go a long way toward eliminating political interference in the administration of health services. It will afford a unique opportunity not only to deprive the last politicians of a happy hunting ground but also to generalize professional direction and supervision of professional matters.

VOLUNTARY HEALTH INSURANCE

Voluntary health insurance as an alternative to a compulsory program has been repeatedly recommended by the American Medical Association. In 1938, this organization announced its support of voluntary cash-indemnity insurance plans to cover, in whole or in part, the costs of emergency or prolonged illness. At the same time the Association recommended the expansion of workmen's compensation laws to provide for meeting the costs of illness sustained as a result of employment in industry, and thus endorsed the principle of required insurance for occupational diseases. In June, 1945, a so-called "Constructive Program for Medical Care" was adopted. One of its fourteen recommendations called for the development in or extension to all localities of voluntary sickness-insurance plans and provision for the extension of these plans to the needy under the principles already established by the American Medical Association. In December, 1945, the House of Delegates adopted a resolution calling for the nation-wide organization of locally administered prepayment medical plans sponsored by medical societies, which would, it was held, achieve all the objectives of the Wagner-Murray-Dingell Bill with far less expense to the people and would provide the highest type of medical care without regimentation. In February, 1946, the Board of Trustees issued a ten-point restatement of the Association's previously announced

fourteen-point program.⁴ Standards for the acceptance of prepayment plans were established. A detailed plan for the development of the voluntary health-insurance program was announced to be in process of being worked out by a subsidiary organization known as Associated Medical Care Plans, and a new unit, the Division of Prepayment Medical Care Plans, was created to administer the voluntary plans under American Medical Association auspices.

The question is justified whether past experience warrants the belief that the American Medical Association can accomplish its objectives.

In 1945, about 2,600,000 persons were enrolled in so-called "medical-society plans." They accounted for approximately half the total membership of voluntary prepayment plans covering physicians' services. At a time when purchasing power was at an all-time high point, only an insignificant fraction of the population had decided to take advantage of the services offered by medical societies. Although the plans had been in operation for several years, some of them had failed to attract substantial numbers of subscribers. A case in point is the Western New York Medical Plan in Buffalo. This plan, established in 1940 and serving six counties with large populations, reported 40,000 subscribers as of the middle of 1945. With the exception of the programs in Oregon and Washington, the great majority of the medical-society plans offer extremely limited service. In 1945, two thirds of the persons enrolled were eligible only for surgical service in hospitals, and in many instances this service was restricted by ceilings on eligibility, the period of care or the total amount of cost. Only one person in seventeen was eligible for physicians' care at the home, office and hospital. In short, the majority of the medical-society plans are distinguished by the fact that exclusions exceed inclusions.

The eligibility requirements often contain a clause barring from the prepaid service persons and families with incomes above the comfort level. In some instances this level is set as low as \$1500 for a single person and \$2500 for a family. By establishing income limits, the majority of the medical-society plans have insured the poorer risks and disregarded the more favorable ones, thus acting contrary to the basic principle of insurance, have made the proposition unattractive to large families, management and labor and have placed the participating physicians in the unenviable position of investigators who have to check the family income to detect the patients who earn more than the limit.

The total cost of medical-society plans varies too widely to allow generalizations. The most successful plan, the Michigan Medical Service, in the middle of 1945 charged monthly rates of \$0.70, \$1.60 and \$2.25 for single subscribers, a family of two and families including all unmarried children up to nineteen years of age, respectively. These prepayments covered surgical service in the hospital and some

ancillary services. The physicians were free to make additional charges to those whose average annual income exceeded \$2000 in the case of single persons and \$2500 in the case of families. The Michigan Hospital Service, an outstanding Blue Cross Plan, charged monthly rates of \$0.80, \$1.80 and \$2.00, respectively, for ward care and \$1.00, \$2.20 and \$2.40 for semi-private care. To qualify for fairly complete hospital care and surgical service in the hospital, a single person had to make monthly prepayments ranging from \$1.50 to \$1.70, and a family of three or more had to pay in advance from \$4.25 to \$4.65 a month. These amounts equaled 1.2 and 1.4 per cent, respectively, of the income of single persons earning \$1500 a year, and 2.5 per cent and 2.8 per cent, respectively, of the annual income of families earning \$2000. It must be borne in mind that in 1945 an annual income of \$2000 was barely sufficient to cover the ordinary living expenses of the average city family with three members. Substantially higher rates and larger proportions of the income would be needed to extend the scope of the services. High prepayment rates, however, defeat their own purpose, since only a small fraction of the population can afford to pay them.

Most of the medical-society plans in actual operation discourage preventive medicine by excluding health examinations, by using deterrents, such as the deductible clause, and by confining medical care to catastrophic illness instead of trying to reduce, if not prevent, the occurrence of serious conditions by providing for early diagnosis and early treatment of disease. Limited in scope as those plans are, they cannot foster psychosomatic medicine. In many cases a premium is placed on surgery, little effort being made to establish and enforce standards covering the competence of those rendering the service for which payment is claimed.

In summary, many medical-society plans are organized merely for the purpose of making financial arrangements for the payment of doctors' bills. Little attention can be paid to the improvement of the quality of service. Judging from the numerous articles appearing in medical journals, many of the physicians participating in these plans are dissatisfied and are looking for "something else." Not a few show keen interest in cash-indemnity plans, although the shortcomings of this method have been proved time and again. In California, the Alameda County Medical Society, in opposition to the state medical society, recommends such a plan, and other county societies are said to have voiced their approval. In Wisconsin, the state medical society has just made an agreement with commercial insurance companies, which are to underwrite a limited indemnity policy, and many physicians are beginning to wonder why the medical society should "sell out" to companies organized for profit.

The policies adopted by medical societies in the past were dictated by necessity. The physicians draw-

ing up the prepayment programs entertained no illusions about the impossibility of establishing at reasonable cost a voluntary health-insurance program providing for complete service, offering unlimited free choice of physicians and paying the participating physicians on a fee-for-service basis. Societies that tried it failed. In California and Michigan, the medical societies had to drop their original full coverage contracts because of heavy financial losses. Between the Scylla of excessively high prepayment rates covering complete service and full payment for professional services and the Charybdis of moderate prepayment rates for complete service with extremely low fees for the physicians, the medical societies chose the only safe way — the offer of inexpensive and limited service to the subscribers and the promise of full payment to the physicians.

These facts, stated and commented on in countless publications in medical journals, indicate that the American Medical Association has taken on a Sisyphean task. It seeks to develop a satisfactory national health-insurance program by voluntary action, although the natural limitations of the voluntary method are well known. It desires to achieve the goal of country-wide organization, although the rank and file of the physicians are divided concerning the basic principles to be applied. Stormy debates are going on over the advantages and disadvantages of cash-indemnity plans and service plans, of combination and separation of professional services and hospitalization, of complete coverage and partial coverage of service, of rigid and liberal eligibility requirements and of individual practice and group practice. The American Medical Association believes that it can make the enactment of a health-insurance law superfluous by promising something better in the future, although a broad and balanced health program is needed now.

* * *

Whatever the fate of the various health bills may be, the wide discussion of the proposals will set in motion many changes in community planning for health services in general and for more effective organization of hospital and professional services in particular.

The problems we are now facing are highly complicated. Their solution requires accurate analysis of facts, correct appraisal of existing medical-care programs, fearless use of reason, constructive criticism of any proposal for the improvement of health services and single-mindedness in carrying out what appears to be a sound policy and one that is in accord with democratic ideals.

As Franklin Delano Roosevelt said in his Jefferson Day Address, written shortly before his death: "The only limit to our realization of tomorrow will be our doubts of today. Let us move forward with strong and active faith."

INVOLVEMENT OF THE CENTRAL NERVOUS SYSTEM IN INFECTIOUS MONONUCLEOSIS*

A Report of Two Cases

CAPTAIN JOHN DER SLADE, M C, A U S

INFECTIOUS mononucleosis is generally regarded as a benign disease having a uniformly good prognosis. In the majority of cases this belief is substantiated, but in occasional cases this disease causes permanent damage and sometimes seriously threatens life.

The clinical features of infectious mononucleosis have been described in detail¹⁻⁶ and there are numerous articles on the hematological findings.^{1, 2, 5, 7-10} There have, however, been relatively few reports dealing with the abnormalities of the central nervous system sometimes encountered.

The first case of involvement of the central nervous system in infectious mononucleosis was reported by Johansen¹¹ in 1931. His patient presented meningismus, drowsiness, impaired memory, dysarthria and weakness, in addition to the usual anginous type of infectious mononucleosis. In the same year Epstein and Dameshek¹² reported a comparable case in which there was ptosis of the right eyelid, a positive Kernig sign, a transiently positive Babinski sign, blurred vision and delirium. Both these patients made complete recoveries within two months.

In 1935, Fledelius¹³ reported a case of infectious mononucleosis complicated by diplopia due to paresis of the left inferior rectus muscle, associated with stiff neck, headache, exaggerated knee jerks and questionable plantar reflexes. Improvement was gradual, with complete recovery in eighty days. In the following year, Sucher and Schwarz¹⁴ described 2 severe cases in which death seemed imminent. The first patient presented drowsiness, horizontal nystagmus, right oculomotor paralysis, ataxia, adiadokokinesis and positive Babinski, Oppenheim and Kernig signs. Improvement in the third week was followed by relapse in the fourth week, with convulsions, left hemiplegia, cyanosis and pulmonary edema. Recovery was effected after seventy-five days. In the second case there was coma, opisthotonus, severe convulsions, left hemiplegia and pulmonary edema, but recovery was rapid, being complete in three weeks.

The second American case was reported in 1937 by Davidsohn.¹⁵ This patient had coma and con-

vulsions. It is noteworthy that this was the first case of encephalitis due to infectious mononucleosis to be proved by the heterophil agglutination reaction, the diagnosis in the previous cases having been based on the combination of lymphadenopathy, lymphocytosis and the finding of the typical cells in blood smears.

In 1937, Gsell¹⁶ reported 5 cases showing involvement of the central nervous system. One patient developed an optic neuritis, the remnants of which were visible a month later. Transient facial paralysis was present in 2 cases. In one of these, a right facial paralysis was followed a week later by involvement of the left facial nerve. In the other case, a right facial palsy lasting a week occurred a month after apparent recovery from an otherwise typical infectious mononucleosis.

Cases of infectious mononucleosis with involvement of the central nervous system have been reported more frequently in recent years. Various parts of the nervous system are primarily involved in different patients, so that the clinical picture may be that of meningitis,¹⁷⁻¹⁹ encephalitis,²⁰⁻²² meningo-encephalitis,²³ encephaloneuronitis,²⁴ encephalomyelitis²⁵ or neuronitis.^{26, 27}

The time interval between the onset of infectious mononucleosis and the development of neurologic abnormality is quite variable. If one excludes headache as a significant symptom, it is seen that involvement of the central nervous system may be apparent as early as the first day of illness¹² or be delayed until the thirty-first day,¹⁶ but it usually occurs in the second week of illness. The signs and symptoms depend on what portion of the nervous system is attacked, and there therefore is considerable variation from one case to another. Table 1 lists the signs and symptoms recorded in the cases reviewed and gives the number of cases in which each finding occurred.

The cerebrospinal-fluid findings parallel the neurologic process, a pleocytosis accompanying meningitic signs and a normal or slight increase in cell count is found in neuronitis and in purely encephalic cases. The cells are predominantly

*From the American Air Force Regional and Air Debarkation Hospital, Hamilton Field, California.

†Headache was present in the majority of cases but is so frequent in apparently uncomplicated cases^{1,23} that it is of little diagnostic value unless it is unusually severe.

lymphocytes. The protein content is usually increased, and the Pandy test may be strongly positive,²⁴ although it is sometimes negative.¹² The mastic curve is variable.^{16, 24}

Little is known of the actual lesions in these cases, because there has been such a paucity of material for histologic study. Ziegler²⁹ has recently reported a case of infectious mononucleosis in which death resulted from rupture of the spleen. At autopsy, focal lesions were found in the liver and kidneys, with mononuclear infiltration, proliferation of retic-

*Prepared from the available data of 32 cases reviewed (including the author's cases)

ulocytes and necrosis suggesting an acute infectious granulomatous process. Ziegler states that the disease appears to be a generalized infection, with specific localization in one or more of the tissues or organs of the body.

In 1939, Thomsen and Vimtrup³⁰ reviewed 500 cases of infectious mononucleosis seen in Copenhagen and described 6 fatal cases. In 4 of these there was no associated disease, death being ascribed to infectious mononucleosis, in all 4 cases death was attributed to respiratory paralysis. In 1 case an autopsy was performed and the histologic study showed severe degeneration of the cells in the region of the respiratory center. With the notable exception of these cases, there have been no deaths from damage to the central nervous system by infectious mononucleosis.

Permanent residuums due to infectious mononucleosis are unusual, but they have been reported by Marchal³¹ (anosmia) and Saksena²⁷ (paralysis of serratus anterior).

The following case reports illustrate the encephalomyelitic and encephalomyelitic types of infectious mononucleosis. In both these patients there was evidence of permanent damage to the nerve tissue. The second case is also remarkable in that it represents one of the few reported cases of infectious mononucleosis in a Negro.^{32, 33}

CASE 1 A 31-year-old man was admitted to the hospital on August 25, 1944, complaining of headache, chills and fever. He had previously been well in all respects until 3

days prior to admission, when he developed swelling below the left ear, malaise and a fever while on a railroad journey. During the next 2 days these symptoms increased in severity, headache occurred, and the patient was seen by a medical officer, who prescribed sulfonamide tablets. The patient took a total of 4 tablets within a period of 12 hours, but the fever, headache and malaise increased and were accompanied by chills, so that as soon as the train reached its destination he was admitted to this hospital. The past history and family history were noncontributory.

Physical examination on admission showed an acutely ill, flushed patient perspiring freely. The temperature was 103°F, the pulse 100, and the respirations 35. The significant findings were diffuse injection of the conjunctivae, slight reddening of the throat, and moderate enlargement of the left postmandibular lymph node, which was nontender. The blood pressure was 105/80. The heart and lungs were normal. The neurologic findings were normal.

The laboratory data are given in Table 2. Blood Kahn reactions were repeatedly negative, as were x-ray studies of the chest and skull. Serum from blood samples taken on September 11 and October 4 were sent to the Army Medical School, where they were found to be negative for the viruses of Western equine encephalitis, St. Louis encephalitis and lymphocytic choriomeningitis.

The temperature spiked to 103°F on the 2nd and 3rd days and then dropped to normal, where it remained on September 1 and 2. It rose to 102°F on September 3, and there was a low grade fever until September 8, when the temperature became normal and remained so. The respiratory rate was normal after the 1st day, and the pulse was proportionate to the temperature.

On symptomatic treatment, the patient seemed to improve, but on August 30 considerable increase in the lymphadenopathy was noted, the cervical, supraclavicular, epitrochlear and popliteal nodes being palpable. On the night of September 2, the 11th day of the illness, the patient developed some difficulty in speech and chewing and stated that his right cheek felt as though it were asleep. These symptoms progressed and extended, coincident with the rise in temperature, and on September 4 examination showed slurred speech, inability to chew, complete bilateral facial paralysis and loss of the gag reflex. The eyes turned upward and slightly to the left when the patient attempted to close them, and there was paralysis of upward gaze without loss of convergence. The right abdominal reflex was sluggish, and the right cremasteric reflex was absent. The sensorium, deep reflexes and cerebellar functions were normal.

The chief complaint at that time was an overwhelming feeling of tiredness. The patient's condition was considered quite serious. Suction apparatus was required to keep the throat and air passages clear, and special nurses were assigned. An additional finding, the true significance of which was in question because of its close similarity to a hysterical tic, was the apparently involuntary sucking, smacking and mumping noises that the patient made with his mouth every few seconds. This phenomenon persisted for 1 week and then gradually disappeared. The gag reflex returned on September 6, and by the next day the lymphadenopathy was generally diminished and the marked fatigue had subsided.

During the next 3 days the patient complained of sharp pains at odd intervals in the posterior cervical and sternocleidomastoid muscles, weakness of which was demonstrated for 2 months. Between September 8 and 11, a small patch of diminished sensitivity to pain developed on the neck just below the ear, first on the right and later on the left. This persisted until September 21. The chewing and swallowing gradually improved, so that by September 15 the patient was eating soft foods without assistance. It was not until September 29 that he was able to eat toast, since his tongue, lips and masseters were so poorly co-ordinated that he frequently bit his lip, tongue or cheek. His speech improved considerably, although it remained explosive at times and vocalization was preceded by inspiratory stridor.

On October 19, the patient was transferred to a general hospital. The significant findings on October 21 were as follows: complete facial paralysis, loss of taste over the anterior two thirds of the tongue, hippus of both pupils, loss of pain and temperature sense over the distribution of the trigeminal nerves, generalized muscle weakness, cogwheel rigidity of the arms, marked weakness of trapezius and sternocleidomastoid

muscles, loss of the left superficial abdominal and cremasteric reflexes, with diminution on the right, and a hopping gait. In November, the patient was transferred to another general hospital. Examination on November 12, the 82nd day of the illness, showed numerous abnormalities. The left leg dragged on walking, and the patient tended to fall toward the left with his eyes open or closed. There was adiadochokinesis, paralysis of upward gaze, loss of pain, vibratory sense, temperature perception and light touch throughout

venereal disease. The only previous hospitalization was in September, 1944, and was due to scabies and pityriasis rosea. At that time peripheral arteriosclerosis was also diagnosed, being manifested by intermittent claudication and x-ray evidence of calcification in the femoral and popliteal arteries. Except for a mild degree of intermittent claudication which had been present for 2 or 3 years, the patient was in apparent good health until 2 weeks prior to admission, when he developed coryza, mild malaise and generalized aching, with

the face, complete bilateral facial paralysis, bilateral weakness of the trapezius muscle, generalized motor weakness throughout the body, slightly greater on the right side than on the left, generalized contraction of the visual fields, somewhat more marked on the left than on the right, and athetoid movements of the hands and fingers. Electroencephalograms were made on November 20 and December 1. These were interpreted as mildly abnormal tracings consistent with diffuse encephalopathy. Despite prolonged hospitalization, physiotherapy, abundant vitamin therapy and a nutritious diet, no additional improvement was obtained, and the patient was discharged from the Army on December 27. In March, 1945, about 200 days after the onset of his illness, the patient reported that his speech was somewhat better

some tingling in the hands, arms and face. This group of symptoms persisted without appreciable change until admission. Physical examination revealed a well developed and well nourished Negro in no apparent discomfort. The temperature was 98°F, the pulse 88 and the respirations 16. The blood pressure was 114/76. Numerous small oval patches of dark-brown pigmentation were scattered irregularly over the trunk and extremities. Peripheral vessels were compressible but easily rolled beneath the fingers. There was moderate enlargement of the anterior and posterior cervical and axillary lymph nodes bilaterally and slight enlargement of the inguinal nodes bilaterally, with no tenderness of any of the nodes. There was bilateral pes planus. No note was made of the reflexes. The laboratory findings are shown in Table 3.

and that he could smile slightly, but that he still had loss of taste, numbness of the face and inability to look upward and had developed a high-pitched whistle in the right ear. CASE 2. A 36-year-old Negro entered the hospital on November 28, 1944, complaining of frontal headache, malaise and generalized aching. The family history was not remarkable except that a maternal uncle had died of hypertensive heart disease. The past history included measles, chicken pox and whooping cough in childhood, without complications or sequelae, uncomplicated mumps in 1926, malaria in 1923, with several recurrences, the last being in 1927, and tonsillectomy in 1924. There was no history of head trauma or

The blood Kahn reaction was negative, as were x-ray studies of the skull, sinuses and chest. On bed rest the patient became more comfortable, but on December 1 the frontal headache became severe and he complained of numbness of the chin. On the same day he noticed some difficulty in chewing, could not control the movements of his tongue and developed weakness of the arms and legs. These symptoms continued, with accentuation of the headache at night, so that by December 4 the following physical findings were apparent: a completely expressionless face with inability to smile, whistle, frown or close the eyes completely, Bell's phenomenon, in which the eyes roll upward when the patient tries to close his eyes, slight ptosis of the eyelids, hyperesthesia over the temporomandibular region,

anesthesia of the chin from the mental foramen of one side to that on the opposite side, dysarthric, slurred speech, absence of the gag reflex, paresis of the masseters and pterygoids, diminished muscle reflexes in the upper extremities, absent knee jerks and ankle jerks, diminished superficial abdominal and cremasteric reflexes, a normal plantar reflex, and adiadokokinesis.

The temperature was normal except on December 1 and 2, when it reached 100 and 99.6°F, respectively. During the next few days the gag reflex returned, and enough strength returned to the masseters so that the patient could eat semisolid food. The frontal headache persisted, being mild during the day but severe at night. Considerable tenderness of the facial muscles was also noted during this phase. The generalized lymphadenopathy was considerably reduced by December 10 and became unnoticeable by December 14.

On December 15, the patient complained of increased aching of the muscles of all extremities. Examination at that time showed generalized muscle tenderness and weakness, with marked weakness of the biceps, triceps, thigh extensors and hamstring muscles, the paresis being somewhat more pronounced on the right than on the left. No further change was noted until December 26, by which time the headaches had ceased. By January 3, 1945, the patient had recovered sufficient strength in the right upper extremity to write a short letter. This was the first objective evidence of improvement.

On January 4, a right-sided foot drop was observed, this had probably been present previously but had not been noticed until the patient was allowed out of bed. On the following day some improvement in the muscle strength of the extremities was apparent, the muscle soreness becoming less as the tone improved. From this date onward the patient made gradual, albeit limited, improvement. By January 15 he had regained some use of the facial muscles, being able to smile slightly and raise his eyebrows. The chin anesthesia was also diminished by this time, and the speech was better, although still somewhat thick. The gait was of the waddling and shuffling type, with a right-sided foot drop. On January 18, the superficial abdominal reflexes were found to be brisk. The cremasteric reflexes were still abnormal, however, in that stimulation of the medial surface of the thigh resulted in lower abdominal reflex spasm but caused no contraction of the dartos muscle. Graduated physiotherapy was begun on January 19, and subsequent improvement was gratifying, the speech becoming practically normal by January 23, the facial expression returning in some measure and the foot drop becoming unnoticeable by January 27. Ophthalmologic examination was negative except for a slight contraction of both visual fields, which remained stationary. Further progress was slow and of limited extent. Except for the first few days of hospitalization, when the patient was drowsy and apathetic, he was mentally alert and cheerful throughout his illness.

General examination on March 17 showed some residual facial weakness, with inability to frown or whistle, and moderate weakness of the pterygoids and temporal muscles. The sternocleidomastoid muscles and those of the extremities were generally soft and flabby, with poor tone and strength, the reflexes in the upper extremities were hypoactive. Knee jerks and ankle jerks were absent, and there was a waddling gait. Finger-to-finger and heel-to-heel tests were well performed.

Physical examination on April 6 showed slight improvement in muscle strength of the extremities and sternocleidomastoids, but the thigh and calf muscles were still tender on deep pressure and squeezing. Stiffness of the upper lip was still apparent on talking and in drinking from a glass, and the gait was shuffling. There was a fine tremor of the fingers and some tremor of the arms and legs when placed on tension. The muscle reflexes of the upper extremities were quite hypoactive, the knee jerks and ankle jerks were absent, but the superficial abdominal and cremasteric reflexes had become active and normal. At that time, 5 months after the onset of illness, it was believed that complete recovery was unlikely and the patient was discharged from the Army on April 14.

DISCUSSION

At the time of admission of both these patients the clinical impression was that of infectious mononucleosis. When the paralytic symptoms appeared,

the differential diagnosis broadened. One of the diseases considered was poliomyelitis. No report on sheep-cell agglutination tests in the acute stages of this disease is to be found in the literature, but Hammon and Lawson²⁴ at the University of California performed Paul-Bunnell tests on serums from 13 patients with paralysis due to poliomyelitis and found that no titer was higher than 1:28.

Clinical observations of these cases support the concept of infectious mononucleosis as a generalized infection with specific localization in one or more of the tissues or organs of the body.²⁹ In the cases described above there was apparently diffuse and spotty involvement of the nervous system. The clinical picture is similar to that produced by viruses of other diseases and suggests that this too may be a virus infection.

The recognition of disease of the central nervous system due to infectious mononucleosis is a simple matter if one is acquainted with the knowledge that it occurs. The actual incidence of such complications is difficult to estimate and is probably quite low. The important thing, however, is the realization that infectious mononucleosis is not always a benign disease. Patients with this disease should not be dismissed lightly, but deserve careful medical observation and attention.

SUMMARY

A review of the literature indicates that infrequent cases of infectious mononucleosis causing disturbances in the central nervous system have been observed.

Cases of fatal respiratory paralysis due to this disease have been recorded.

Two cases are reported in which infectious mononucleosis resulted in such severe damage to the central nervous system that the patients were declared unfit for further military service.

It is emphasized that infectious mononucleosis is a potentially serious disease, worthy of respect as a generalized virus infection that may threaten life.

MEDICAL PROGRESS

FLUORINE AND DENTAL CARIES

VLADO A. GETTING, M.D., D.R.P.H.*

BOSTON

PREVALENCE OF DENTAL CARIES

DENTAL caries is perhaps the most widespread of all diseases of mankind and is one from which very few persons escape, especially in civilized races. It has been demonstrated that a positive correlation exists between the primitive (carnivorous) diets of Eskimos in Alaska and their relative freedom from dental decay.¹ A high prevalence of dental decay, however, is found among Eskimos who live in cities and consume a civilized diet. Practically every adult and almost every child over six years of age has suffered from dental defects.² These defects often induce a train of related maladies that could have been prevented by proper dental care. Dental diseases are not limited to any group and attack all persons, regardless of age, sex, geographical location or economic status.

Dental caries is the destroyer of most teeth that are lost by persons under thirty, thereafter pyorrhea assumes first rank as the cause of loss of teeth. Caries begins as soon as a child has teeth. Over ninety-five per cent of children ten years of age have one or more decayed permanent teeth. By the time the child reaches eighteen, nine permanent teeth, on an average, have become decayed and several extractions have had to be made. The loss of certain teeth upsets the proper alignment of others and brings about malocclusion and predisposes to pyorrhea, the prime cause of loss of teeth in later life. Moreover, diseased teeth and gums may cause disease, directly or indirectly, in adjacent as well as other parts of the body.

Once a defect is produced by decay, evidence of

its existence is never obliterated.³ It is therefore possible by direct examination to determine what has happened to teeth in the past. The permanent teeth with defects caused by present and past attacks of caries are classified in three groups—decayed teeth, those with open carious lesions requiring treatment by fillings, missing teeth, those already extracted or requiring immediate extraction because of extensive destruction of caries, and filled teeth, those previously carious but with evidence of treatment in the form of fillings.⁴ By common usage and for the purpose of brevity, teeth so affected are collectively designated by the symbol "DMF" (decayed, missing and filled).

Because of the characteristic accumulation of caries stigmas with increasing age, the increment in the number of DMF teeth or of DMF surfaces per year per person may be taken as a measure of the incidence of caries. The prevalence of caries may be measured in several ways—by the ratio of the number of persons per 100 population having one or more DMF teeth, the total DMF teeth per person, and the number of DMF surfaces per person, which gives a fuller comparison than either of the foregoing, since each tooth may be attacked on several surfaces.

EPIDEMIOLOGY OF DENTAL CARIES

Age

One of the most significant factors associated with increased dental caries is age. Studies made in 1940 by Klein and Palmer⁵ on 6200 children in Hagerstown, Maryland, and in the same year by Sloman and Sharp⁶ on 6300 high-school children in San Francisco yielded definite evidence of the accumulative destruction caused by dental caries. At six

*Commissioner, Massachusetts Department of Public Health and lecturer in public health practice, Harvard School of Public Health

years of age, 15.9 per cent of the Hagerstown children had one or more DMF teeth, the percentage increased each year until by eighteen years of age it was 96.6 per cent. The San Francisco high-school children showed an increase from 91.0 per cent at the age of thirteen to 97.2 per cent at eighteen. If the second method of analysis is used, the number of DMF teeth per child in the Hagerstown group increased from 0.29 at the age of six to 9.25 at nineteen, and that in the San Francisco children increased from 3.8 at the age of twelve to 8.3 at eighteen. When the same method of comparison was applied to an adult population in New York City in 1939 by Hollander and Dunning,⁷ it revealed a steady increment of tooth destruction with advancement in age, for example, at twenty to twenty-four years there were 15.82 DMF teeth per person, at forty to forty-four years, 21.61, at fifty to fifty-four years, 22.36, and at sixty to sixty-four years, 23.37. If the third method of comparison (DMF surfaces per person) is applied to the Hagerstown and New York City data, it is found that there was a constant increase of tooth decay with advancing age. At six years of age the Hagerstown children averaged 0.38 DMF surfaces per child, at ten years 4.87 and at fifteen years 13.35, whereas in adults in New York City the average increased from 31.52 at the age of twenty to twenty-four to 70.09 at the age of sixty-five and over.

Sex

Several observers⁸⁻¹¹ have noted a greater prevalence of dental caries among females than among males, but this is probably due to the earlier eruption of the permanent teeth rather than to a predisposition to the formation of caries. Females have a greater amount of dental decay than do males of the same age. In 1938, however, Klein and Palmer^{12, 13} demonstrated that this difference is also due to the fact that permanent teeth erupt earlier in girls than they do in boys. Actually, therefore, if a comparison of the age of the teeth is made for the two sexes, there is no significant difference in dental decay until the age of fifteen years. Thereafter there is a gradual increment of dental decay in females with advancing age.

Race

Only scattered data on the difference in the prevalence of caries observed in different races are available. They indicate that race is a significant factor. Negro children have lower rates of DMF teeth per person than do white children,³ the difference increasing with age. Thus, at ten years of age, in the white children of Hagerstown and Baltimore^{4, 6} the rate was 2.5, compared with 1.6 in Negro children of the same communities. In Indian children of the same age examined by Klein and Palmer¹⁴ the rate was 1.3, whereas in Navajo children of this age it was 0.5. At fifteen years of age the rate for

Hagerstown white children was 6.6, that for San Francisco white children was 6.5, that for Hagerstown Negro children was 4.1, and that for Navajo children was 3.1. In other words, the white children had about one and a half times as many decayed, missing or filled permanent teeth as did the Negro children and twice as many as did the Navajo children.

Familial Susceptibility

Several investigators¹⁵⁻²⁰ have studied familial susceptibility to dental caries. Although their findings indicate a significant difference between different families, it is not clear whether these observed differences are in reality due to inherited (Mendelian) factors or whether they are not more probably due to environmental factors, such as family eating habits, consumption of candy, poor economic status and other factors that are common to the members of the same household.

Klein and Palmer²¹ studied 4400 white elementary-school children in Hagerstown and found 117 with extreme susceptibility to caries and 184 with immunity to it. The susceptible children had 182 siblings, whereas the immune children had 306, all of whom had been examined. Studies of these records revealed that the tendency toward caries of the siblings of immune children was about half that of the siblings of susceptible children.

Economic Status

The literature tends to suggest that economic status does not markedly affect the prevalence of caries, although the amount of dental work is related directly to the income of the family.²²⁻²⁴ Klein and Palmer²⁵ studied the caries prevalence rate for 200,000 children in forty New Jersey communities. They concluded that the intrinsic tendency of children to experience attacks on the permanent teeth by caries does not depend on the economic status of the community in which they live. The volume of dental care in the form of fillings in the permanent teeth, however, markedly increased with improvement in the economic level of the community, the odontothanatotic rate (the number of permanent teeth extracted and indicated for extraction per 100 children) diminishes as the economic level rises.

Conclusions contrary to these reports were reached by Hyde,²⁶ who examined inhabitants of Massachusetts at the Boston Armed Forces Induction Station. The incidence of caries (DMF teeth) per person was highest in the most prosperous communities and lowest in the poorest communities. The English and Irish had the greatest amount of dental decay, whereas the Negroes and Chinese had the least. Three times as many selectees from Irish communities as from Portuguese or Russian (Jewish) communities were rejected for dental defects. The evaluation of the influence of economic factors on

dental caries must in the final analysis await a detailed study of other factors that are usually related to economic ones, such as diet and outdoor activity

Geographical Location

There appears to be a definite correlation between the prevalence of dental caries and several factors involved in geographical location. These factors pertain not only to certain locations within the United States but also to geologic formations and

believes that areas having high annual total hours of sunshine have less caries than do areas with fewer hours of sunshine. Nizel and Bibby²⁹ are convinced that geographic variations have a definite influence on the prevalence of dental caries, as was demonstrated on examination of 22,117 soldiers in Camp Edwards, Massachusetts. Many earlier observers — Lewis³⁰ in 1865, Britten and Perrott³¹ for draftees in World War I, Ferguson³² for naval recruits and Senn³³ for aviation cadets in World War II — have shown that New Englanders had a higher exemp-

*Owing to the small number of recruits from certain areas those from contiguous states were tabulated together and each state was given the same rate.

†Figure happened to be the same for these states.

‡States are arranged in the order of descending prevalence.

climatologic differences. Mills,²⁷ after studying the prevalence of caries in different latitudes, concluded that rates are highest in the northern and lowest in the southern areas of the country. In latitudes 25 to 26° the prevalence rates of DMF teeth were under 300 per 100 boys, whereas in latitudes 37 to 48° they were above 300. The rate increased by about 15 units for each degree farther north. East²⁸

believes that areas having high annual total hours of sunshine have less caries than do areas with fewer hours of sunshine. Nizel and Bibby believe that the consistent repetition of this phenomenon over a period of eighty years eliminates all possibility of chance and establishes geographic variation in the prevalence of dental decay. The geographic prevalence of caries in draftees and recruits is summarized in Table 1.

The role of the mineral composition of public water supplies in relation to dental caries has been extensively studied by many authors, especially Dean³⁴ and East³⁵. Both positive and negative relations between hardness of water and prevalence of caries have been reported by different investigators. East³⁶ offers evidence that users of hard water have less caries than do users of soft water. It has, however, been pointed out by Dean³⁷ and many others that this phenomenon is not the result of hard waters but rather the presence of fluorides in them. The role that fluorine plays in the prevention of caries is discussed in detail later in this paper. Nizel and Bibby, however, noted that caries is prevalent in regions with podzol and gray-brown podzolic soil and that wide variations in susceptibility to it occur in association with the red and yellow, chernozem and chestnut and prairie-soil regions of the south and the midwestern states. Finally, these authors urge more extensive investigation of soils in relation to dental caries, pointing out that there may be other rare elements besides fluorine that influence the incidence of dental decay.

Diet

McCollum,⁸ after examining the literature relating to the etiology of dental caries during recent years, concluded that there is an agreement among authors that carious lesions are caused by acid decomposition of the tooth enamel and subsequently the dentin, associated with proleolytic destruction of the organic substance of the tooth. There is unanimity of opinion that caries is restricted to persons and animals that have a liberal carbohydrate diet, whereas carnivorous men and animals do not suffer from this disease. Dental caries does not attack the surfaces of teeth indiscriminately but occurs only at sites that favor the lodgment of food particles or on surfaces of the enamel that harbor mucinous plaques. In these sites, acid is formed by fermentation of carbohydrates by micro-organisms and is protected by the plaques against being washed away by saliva or neutralized by salivary alkalinity.

Faulty structure in the enamel may cause the lodging of food particles in fissures and pits and thereby predispose to the formation of dental caries. The filling of these defects prior to decay is known as prophylactic odontotomy and has proved to be an effective means of prevention of caries. Such defects, however, may be the result of dietary deficiency. When, owing to vitamin A deficiency, the enamel-forming cells are injured, enamel prisms that are less dense than normal ones or are incomplete as to length and imperfectly fitted together form defective enamel. In severe cases vitamin A deficiency causes hypoplastic teeth, characterized by thin enamel deficient in hardness, in milder deficiency there may be pitting.

Vitamin D deficiency, with the disturbance of calcium and phosphate metabolism of rickets, may

cause defects in teeth, since the enamel-forming cells are unable to withdraw from the blood the materials required for the formation of normal cells. McBeath³⁸ and Erpf³⁹ found a seasonal variation in the incidence of dental caries, the highest incidence of new cavities occurred in late winter and spring, when the amount of sunshine was the lowest. It is thus apparent that the lack of sunshine may be to blame for a lowered production of vitamin D in the bodies of the children as a result of the reduced amount of ultraviolet light. This decrease was manifested in part by the increased amount of dental caries observed during the period of low vitamin D production.

The eating of sugar and candy has been believed by many authors to cause dental decay. Bunting and his associates⁴¹ were able to demonstrate that children classed as immune to caries who were allowed to eat about 3 pounds of candy a week soon became susceptible to dental decay. Thus, sugar seems to be a greater menace to the teeth than are starchy foods. This observation has been verified by studying the diets of starch-eating primitives, who usually have relatively small amounts of dental decay.

In conclusion, it may be said that if a person has an optimal diet during the developmental period of the teeth, they will be free from defects such as pits, fissures and hypoplastic enamel. Subsistence throughout life on a strictly carnivorous diet prevents caries. The presence of considerable carbohydrate, especially sugar, in the diet is likely to predispose to dental decay. The elimination of sugar from the diet, with the substitution of starch, affords a less favorable oral medium for the development of acid-forming organisms and so protects the teeth against acid decomposition. Vigorous chewing of raw fruits or raw vegetables, which also act as detergents, tends to prevent dental caries.

Mouth Bacteria

Bibby⁵ summarized as follows the reasons why bacteria are believed to be of fundamental importance in causing dental caries. Tooth destruction progresses from the outside of the teeth inward, the sites at which caries occur are the places at which foods accumulate, an association has been shown to exist between the acidogenic properties—carbohydrate content—of diets and their effects in producing caries, as yet acids are the only chemical and biologic agents that are known to have the power of destroying dental enamel and bringing about decalcification of dentin, and lastly, bacteria are the only agents existing in the mouth that are known to have the power of producing acid from foodstuffs.

Accumulated evidence indicates that acid is definitely concerned in tooth decay. Enright et al.⁴⁰ demonstrated that cavities like those of caries can be produced by the action of acids. Bunting⁴¹ and

Bibby⁴² were able to produce similar cavities by bacteria grown in the presence of carbohydrates. Oslick⁴³ found that the acidity of dental mucous plaques is increased when fermentable carbohydrates represent. Deakins⁴⁴ demonstrated that the chemical changes that occur during the formation of caries correspond to those caused by the action of acid. Miller⁴⁵ and Kanthak⁴⁶ found organic acids in carious dentin. Finally, Miller⁴⁷ and Hodge and Inn⁴⁸ were able to demonstrate that certain agents that prevent acid formation from carbohydrates prevent dental caries in animals, and Dean, Jay, Arnold, McClure and Elvove⁴⁹ and Day⁵⁰ were able to demonstrate the same fact for man.

Culture studies by various investigators have led them to postulate a causative relation between dental caries and certain bacteria, on this basis lactobacilli, streptococci, fusiform organisms, species of Cladothrix and Leptothrix and anaerobic bacteria have been named as etiologic agents of dental caries. Bunting et al⁵¹ have reported an extensive study of the association between increases in the number of lactobacilli and dental caries, lactobacilli were shown to decrease when cavities were filled or carious teeth were extracted. As yet no specific bacteria have been positively proved to be the prime cause of dental decay. It may therefore be concluded that several types of bacteria are associated with dental decay and that any organism that produces acid in the mouth is a potential cause of decalcification. Experiments conducted by Bibby,⁴² however, indicate that lactobacilli are present in a relatively small number and may be caused by conditions brought about through dental caries, whereas streptococci are present in relatively large numbers, grow more rapidly, are active in bringing about chemical changes and may in effect be the bacterial flora chiefly responsible for dental decay.

Cost of Dental Care

It is readily understood that the repair of the constant damage produced by dental caries is costing the Nation large sums of money annually. These costs are for repairing teeth that develop cavities, extracting those that are beyond repair and providing replacements for lost teeth that are required for the mastication of food. Detailed information regarding the prevalence of dental defects among the entire adult population of the United States is limited. Surgeon General Parran² in a statement before a congressional committee in a hearing on a bill to provide greater facilities for dental care gave an estimate, prepared by one of the dentists of the United States Public Health Service, of the accumulated dental needs of the population. In the same statement he gave a list of the average charges for various items in dental care. On the basis of these figures Table 2 has been prepared. It shows that it would cost over \$4,000,000,000 to repair the damage done by dental caries and pyorrhea to

the teeth of the American population, the share of Massachusetts being nearly \$134,000,000. This amount represents a per capita cost of \$31.00. Once the teeth were put in good repair, the constant inroads of dental caries would produce additional damage, the repair of which would cost further sums.

It is obvious that there are not sufficient dentists and dental assistants in the Nation to take care of this accumulated volume of dental work. The best

TABLE 2 Dental Needs for the United States

ITEMS	NO NEEDED	AVERAGE COST PER ITEM	TOTAL COST	COST FOR MASSACHUSETTS
Extractions	238,500,000	\$2.00	\$477,000,000	\$15,700,000
Fillings	632,000,000	3.50	2,212,000,000	72,600,000
Prophylaxes	125,000,000	2.00	250,000,000	8,200,000
Dental treatments	20,000,000	2.00	40,000,000	1,300,000
Crowns and bridges	39,500,000	15.00	592,500,000	19,500,000
Partial dentures	20,000,000	25.00	500,000,000	16,500,000
Totals			\$4,071,500,000	\$133,800,000

study available on the total annual expenditures for dental care in the United States is that made in 1929 by Leven and Beck,⁵² who estimated the gross annual income of dentists as \$446,000,000, about one ninth of the \$4,000,000,000 mentioned above. In other words, it would take the men now trained in dentistry approximately nine years to care for the accumulated needs of the American people.

On the premise that the destruction of teeth by dental caries and pyorrhea will continue at the present rate, Dollar⁵³ has estimated the annual cost of maintaining the teeth of this population in good repair as \$1,300,000,000. This is about three times as much as is being expended for dental service at the present time. The figure for Massachusetts would be almost \$43,000,000.

It is self-evident that if the inhabitants of this country are to have good teeth, either there must be provided a sufficient number of dentists and dental assistants who are adequately paid or ways must be found for halting the inroads of dental caries and pyorrhea. This is the reason why those interested in dental health^{54, 55} are looking so hopefully toward the use of fluorine and of other agents that give promise of reducing the annual damage by diseases of the teeth and gums. For this reason also, health departments should have a part in carrying on studies that will uncover other measures for stopping this annual drain on the health, energy and financial resources of the Nation.

(To be concluded)

CASE 32231

PRESENTATION OF CASE

A fifty-one-year-old housewife entered the hospital because of burning, tingling and pain in the fingers

The patient was allegedly well until six months before admission, when she began having a dull aching in her fingertips followed several weeks later by severe burning and tingling. At first these symptoms came in paroxysms, but they gradually became constant, lasting day and night and spreading to involve the entire hands. There was no definite story of weakness, but the paresthesias limited the use of her hands to such an extent that they became stiff and she was finally unable to feed herself. She saw her physician, who diagnosed anemia and treated her with liver and iron injections, as well as with many vitamin preparations. During this medication she developed anorexia, and three weeks before entry she began to vomit everything she ate. Concomitantly, she noticed swelling of the ankles, mild pain in the calves and some difficulty in walking. The pains in her arms were somewhat less when she sat on the edge of her bed, and she spent much time in that position.

In the past her health had been good except for an attack of gout in the great toe thirty years previously and a tubal pregnancy followed by a salpingo-oophorectomy seventeen years before entry. She had had two normal deliveries. The menopause had occurred four and a half years before entry.

Physical examination revealed a well developed but rather obese pale woman in no acute distress. The mucous membranes were pale. The skin was dry. The tongue had smooth edges, but it was not red and there was no cheilosis. An inconstant Grade I systolic murmur was heard over the apex. The lungs were clear. The abdomen was obese. The arms showed moderate weakness of all motions and marked weakness of the hands. There was considerable limitation of passive motion of the fingers, elbows and shoulders. The wrists and shoulders were somewhat tender. There was hyperesthesia to pain, and vibration and position senses were normal. The

thenar eminences were flattened. The legs showed no limitation of motion and no paresthesias. Vibration and position senses were moderately decreased. There was moderate calf tenderness.

The temperature, pulse and respirations were normal. The blood pressure was 150 systolic, 85 diastolic.

Examination of the blood showed a red-cell count of 3,100,000, with a hemoglobin of 9 gm. The smear was reported as normocytic and normochromic. The white-cell count was 23,500, with 90 per cent neutrophils and 9 per cent lymphocytes. The non-protein nitrogen was 92 mg per 100 cc, and the protein 5.7 gm. The Hinton and Wassermann tests were negative. The urine showed many white cells in clumps but no albumin or casts. The specific gravity was 1.010. Culture revealed a moderate number of colon bacilli.

X-ray films of the chest and a gastrointestinal series were reported normal.

Lumbar puncture showed an initial pressure equivalent to 170 mm of water and a final pressure of 140 mm, with free dynamics. There were no cells, and the ammonium sulfate ring-test was negative. The total protein was 21 mg per 100 cc. Gold-sol and Wassermann tests were negative.

The patient was extremely unco-operative and resisted efforts to mobilize her. She complained constantly of the pains in her joints and muscles. She was oriented during the day, but at night she had severe delirium with nightmares and hallucinations despite sodium amytal sedation.

On the fifth hospital day she was transfused with 500 cc of whole blood. On the ninth hospital day the white-cell count reached 30,000, with 82 per cent neutrophils and 18 per cent lymphocytes, some of which appeared atypical. Further urine studies showed a + test for albumin, failure to concentrate to a specific gravity of more than 1.014, and less than 5 per cent excretion of phenolsulfonephthalein at the end of two hours. The patient gradually became oliguric and passed into coma. On the nineteenth hospital day the nonprotein nitrogen reached 140 mg per 100 cc and the carbon dioxide 7.5 milliequiv per liter. She died on the twentieth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. MARLAN W. ROPES: I am sure that the one safe statement is that I am unable to make a diagnosis that will completely fit this picture. There are a few obvious facts: the patient was in uremia when she came to the hospital, she had an infection of the urinary tract, she had anemia, leukocytosis and neurologic and skeletal symptoms, and she died of renal failure. Several diagnoses are suggested by these symptoms, and the problem is to pick one that will correlate all the findings.

In any patient with renal disease, anemia and skeletal pain one thinks of multiple myeloma. There is no more than that to support this diagnosis, how-

in the urine. The strongest point in favor of pyelonephritis is the presence of urinary-tract infection at the time of admission. Unfortunately, we know nothing about the duration of the infection. Apparently there were no symptoms associated with the genitourinary tract before her present illness. In fact the only renal disease that I was able to think of that gives as few changes in the urine is amyloid disease, which frequently shows only albumin in the urine. I have never happened to hear of or see a patient with so little albumin in the urine at the time of death from amyloid disease of the kidney. That would not rule it out, however. We have seen patients who died of amyloid disease who had had nothing except albumin in the urine throughout the course of the disease.

It is of interest to compare this case with one reported by Lengh* in 1937. The patient was a forty-seven-year-old woman who six months before entry had pain in the joints, paresthesias and anemia and at the time of admission had some albumin in the urine. She died soon after her hospital admission and at autopsy was found to have pyelonephritis, with stones and atypical amyloid disease, masses of amyloid being present in the joint tissues. It also involved the tongue and many vessel walls—a few in the liver, spleen and heart and many in the kidneys. The explanation that Lengh gave in this case was that it was amyloid disease secondary to severe infection—a pyelonephritis of years' duration. The involvement of tissues in that case is much like that reported in atypical amyloid disease or so-called "paramyloidosis," in which the liver and spleen are not involved but amyloid is present in muscles, joints, bones, the tongue and thyroid gland and the vessel walls, often in the kidneys. Interestingly enough this particular atypical form is usually not secondary to any known cause. Infection is generally not found. In the secondary type of amyloidosis in which the liver and spleen are often involved the cause of the amyloid is usually an infection.

In trying to put together the diseases suggested by the neurologic and skeletal symptoms and the diseases suggested by the kidney disease, I find it difficult to offer an adequate explanation of the entire picture. I shall say first that she had an infection of the urinary tract. It is obvious that she had uremia, which was probably due, I shall say, to amyloid disease. Whether or not the amyloid disease was secondary either to one of the group of connective-tissue diseases that I have discussed or to the renal infection, or whether it represented the so-called "atypical amyloid," which would explain all the other symptoms, I cannot tell. The possibility of explaining it on the basis of atypical amyloidosis is intriguing.

DR BERNARD JACOBSON In addition to amyloid disease, would you not consider Bence-Jones proteinuria as a possibility?

DR ROPES I mentioned Bence-Jones proteinuria as a cause of the renal disease, but in the absence of other evidence I ruled it out. The renal evidence is satisfactory, but I cannot explain the rest of the picture on that basis.

DR CHESTER M JONES We did not know what the patient had. We thought of many of the things that Dr Ropes has outlined. As a matter of fact, chronic renal disease was not too seriously considered for several days because the first and second specimens of urine had no albumin, the third and fourth specimens gave only a + test for albumin and contained white cells but no other formed elements. My feeling was that she had chronic glomerulonephritis. She had a fixation of gravity at 1010, and practically no dye was excreted in the phenolsulfonephthalein test. The other findings were those of a person who had prolonged anorexia and vomiting, with malnutrition and deficiency disease, and possibly a thiamin lack, with a peripheral neuritis, for which she was also treated. Incidentally she had been treated with liver by her own doctor without any apparent improvement. Dermatomyositis was considered, but there was no evidence that that existed.

CLINICAL DIAGNOSES

Chronic glomerulonephritis
Uremia
Peripheral neuritis

DR ROPES'S DIAGNOSES

Chronic pyelonephritis
Uremia
Amyloid disease (? atypical form)

ANATOMICAL DIAGNOSES

Diffuse plasma-cell myeloma
Lower nephron nephrosis (Bence-Jones proteinuria type)
Atypical or "primary" amyloid disease, involving muscles, joints, heart and blood vessels
Chronic pyelonephritis, minimal

PATHOLOGICAL DISCUSSION

DR MALLORY Obviously this was a very difficult case for diagnosis, and Dr Ropes has come astoundingly close. Everything can be explained on the basis of one condition and its recognized complications. The patient did have extensive amyloid disease with the distribution of the so-called "atypical" or "primary" type, with marked involvement of the muscles, joints, heart and blood vessels. The liver, spleen and kidneys were entirely free from the disease. The kidneys showed massive plugging of all the lower nephrons with hyaline casts and severe interstitial nephritis, with a few foci of pyelonephritis, which were relatively unimportant.

*Lengh, F. Zur Kenntnis der Amyloidablagerung in den Gelenken. *Zentralblatt f. Path. u. path. Anat.* 69:1-5, 1937.

ever, unless we assume the unlikely possibility that the atypical lymphocytes might have been plasma cells. Such a diagnosis would not explain the degree of muscle involvement or paresthesias. Similarly, with paresthesias, anemia and smooth tongue edges, one thinks of pernicious anemia, but we are told that on at least one examination the blood was normocytic and normochromic. She had had some treatment that might have modified the picture, but there was no evidence in the blood examination that she had pernicious anemia. Furthermore, the neurologic examination was essentially normal. The vibration and position senses were normal, except for slight reduction in the legs. Also this diagnosis would not explain the renal involvement or the degree of muscle involvement. The neurologic findings suggest polyneuritis, but the course is against such a diagnosis. The relatively normal neurologic examination is against it, and particularly against it is the normal spinal fluid. If such a diagnosis were to be made it would be separate from the renal involvement. I think we can rule that diagnosis out. One can also rule out muscular dystrophy. In fact the degree of muscle change is so slight that I doubt that such a diagnosis could even be considered. There was weakness but relatively little, — more pain than weakness, — and the paresthesias were out of proportion for such a diagnosis. There is minimal evidence to suggest leukemia or lymphoma, and I think that they can be ruled out.

In any constitutional disease that has joint and muscle involvement, paresthesias and anemia, we have to think of connective-tissue diseases, such as rheumatoid arthritis, disseminated lupus erythematosus, periarteritis nodosa, dermatomyositis and scleroderma. The last can be easily ruled out because there was no skin involvement. Dermatomyositis is possible because of the degree of involvement of the muscles. Absence of real inflammation of the muscles and absence of weakness in the trunk or pharyngeal muscles would be unlikely in a severe case of dermatomyositis. Again, this would not explain the renal involvement. The other three conditions cannot be ruled out, although I find little evidence for any of them. The joint and muscle symptoms are consistent with rheumatoid arthritis. Unfortunately we have no x-ray films of the joints, and I judge that the other films were negative.

DR TRACY B. MALLORY: There is one shoulder joint showing in this chest film.

DR ROPES: In it there is nothing except the suggestion of some loss of calcium from the bones. There is no definite soft-tissue involvement of which I can be sure.

There is a story of a joint attack in the past that was called "gout." I think that this is of no significance so far as the present illness goes. Indeed, I doubt that she had gout. It is extremely rare in women, and an attack of acute arthritis involving

the great toe is often called gout without further evidence. My feeling is that she had another type of arthritis in the great toe. We cannot rule it out, but I think that she did not have gout with a progressive arteriosclerosis causing the renal failure.

If rheumatoid arthritis is to be considered as the cause of the recent condition, it would not explain the renal involvement unless the patient had amyloidosis. The development of amyloid in rheumatoid arthritis within a six-month period is unusual. It occurs after various changes in the blood have taken place, such as an increased globulin, but in our experience it does not occur until after at least six months and usually after a year of disease. The evidence we have is that her illness did not start until six months before admission. I doubt that she had amyloid due to rheumatoid arthritis.

Joint and muscle symptoms can occur in disseminated lupus, but here, as in rheumatoid arthritis, one would not expect such severe paresthesias or marked muscle changes. The diagnosis of lupus would, of course, explain the renal involvement and renal failure as the cause of death, but it is impossible to make the diagnosis of disseminated lupus in the absence of involvement of the skin and serous membranes. Furthermore, a leukocytosis of this degree would be extremely unusual, if not unknown, in lupus without obvious infection. In fact the majority of cases of disseminated lupus, even with infection, do not elevate the neutrophil count to this level.

Periarteritis nodosa is perhaps more difficult to rule out despite the fact that there is again no definite evidence for it. The degree of paresthesia is greater than one ordinarily sees with periarteritis nodosa, and the degree of muscle weakness and muscle change is much greater than one ordinarily sees. If the renal involvement were due to periarteritis nodosa one would expect more abnormalities in the urine than a + test for albumin with, on one occasion, many white cells. I am assuming that the other urinary specimens were essentially negative. So the group of diseases suggested by the skeletal and neurologic symptoms do not explain the entire picture.

I might turn to the renal involvement and consider the likely causes of renal failure that lead to death. There are few conditions that show an essentially negative urine at the time of renal failure. From the whole picture — the age, the lack of arteriosclerosis elsewhere and the relatively negative urinary findings — it is unlikely that the patient had nephritis on the basis of arteriosclerotic changes. Chronic glomerulonephritis cannot be ruled out. She went slowly into uremia, and at that time she was known to have an infection of the urinary tract, but again, one would surely expect more changes in the urine. Similarly pyelonephritis cannot be ruled out, although one would expect more changes

present a tumor of this size. It is usually a small tumor, whose only symptom is intermittent obstruction, and that does not fit the picture in this case, because this is a large tumor with extensive ulceration of the mucous membrane as shown by x-ray and by the occult blood in the stools.

The time is nearly up and I shall not discuss this any further. I shall say that the most probable

he would have been able to tell more accurately, but I should say that this was a lymphoblastoma or lymphosarcoma of the jejunum.

DR TRACY B. MALLORY: Dr Simeone, will you give the operative findings?

DR F. SIMEONE: At operation this patient had a large mass about 9 or 10 cm. in diameter, which was stony hard to palpation and, on the surface,

FIGURE 1 X-Ray Film Showing Displacement of the Proximal Transverse Colon by a Midabdominal Mass

diagnosis is tumor of the small bowel, not of the carcinomatous type, which would cause constriction and would be small. Because of its size the tumor had probably grown both within and outside the bowel, invading the mesentery. Myoma, fibroma and lipoma are possibilities but the more frequent variety is lymphoma, perhaps of the Hodgkin's type. We have no further evidence of that, however. Perhaps if an expert hematologist had seen a smear

appeared white. The mass was freely movable in the horizontal plane from right to left and back again, but could not be moved in the vertical plane. It could not be delivered into the wound. The mass had infiltrated the mesentery to a great extent. On tracing it down it was found to extend to the origin of the midcolic artery and for that reason we believed that it was certainly incurable, but we wanted to make every effort to remove the tumor.

One very peculiar and I think probably pathognomonic finding was that there were foreign-body giant cells around the casts within the tubules. I have never seen that except in Bence-Jones proteinuria. I was first shown the kidney in this case, and because of this finding asked to see the bone marrow, which proved to be diffusely invaded with plasma cells. So the primary diagnosis is diffuse plasma-cell myeloma, with Bence-Jones proteinuria, the so-called "myeloma kidney." Amyloid disease is a recognized sequel of myeloma and oddly enough nearly always shows the distribution of so-called "primary" amyloidosis rather than that of the usual secondary type.

DR JACOBSON: What was the serum protein value?

DR JONES: It was 5.7 gm per 100 cc. The service considered doing a bone-marrow biopsy, but the patient was so ill that it was not done.

DR MALLORY: I do not believe that the serum protein value was checked.

DR. ROPES: The low serum protein might be explained by the fact that she had lost albumin in the urine over a long period.

DR JACOBSON: It is interesting that this is one of the few cases autopsied here that has shown atypical amyloid distribution.

DR MALLORY: I can remember only one other

CASE 32232

PRESENTATION OF CASE

A fifty-three-year-old shoe cutter entered the hospital because of progressive weakness, and loss of weight.

The patient had been in apparent good health until ten months before entry, when he vomited four times in one night. He went to a local hospital, where x-ray films were taken, but was sent home with some pills. He did not vomit again, but became progressively weaker and lost about 15 pounds. Several weeks before entry he noticed increasing anorexia, constipation, flatulence and a feeling of abdominal fullness. The stools were darker than usual, but not black, and he noticed no blood. He also suffered from sour stomach, which was aggravated when he was lying down.

Physical examination showed a pale, lethargic man, with evidence of recent weight loss. The mouth was edentulous. The heart and lungs were normal. At the level of the umbilicus there was an irregular, hard, freely movable abdominal mass, about 12 cm in diameter, which could readily be shifted to either side of the umbilicus and caused marked local protuberance of the abdomen. Peristaltic sounds were rather high pitched. The liver could not be palpated. Rectal examination was negative except for moderate enlargement of the prostate.

The temperature, pulse and respirations were normal. The blood pressure was 120 systolic, 60 diastolic.

Examination of the blood revealed a hemoglobin of 8 gm. The white-cell count was 8200. The non-protein nitrogen was 31 mg and the total protein 6.8 gm per 100 cc, and the chloride 102 milliequivalents per liter. The prothrombin time was normal. The urine was normal. Repeated stool examinations were guaiac positive.

X-ray examination of the abdomen, including an intravenous pyelogram, showed normal kidneys. There were several diverticula of the urinary bladder, measuring up to 4 by 1.5 cm. A barium enema readily filled the entire colon and terminal ileum, showing them to be normal in form and function. The colon contained some fecal material, particularly in the ascending and proximal transverse portions. On the post-evacuation film the proximal transverse colon was displaced slightly upward by extrinsic pressure from the midabdominal mass, which was shifted upward as compared with its position on the pre-evacuation film (Fig 1). A small intestinal enema revealed an area of ulceration, measuring approximately 6 cm, in the upper jejunum, within the freely movable palpable mass (Fig 2). The bowel was slightly narrowed in the region of the ulceration, but most of the mass lay outside the bowel lumen, pushing aside the remainder of the intestinal loops in this area. Some of these loops seemed to be attached to the tumor mass.

An operation was performed on the ninth hospital day.

DIFFERENTIAL DIAGNOSIS

DR HORACE K. SOWLES: May we see the x-ray films?

DR RICHARD SCHATZKI: The mass is fairly well visualized in the post-evacuation film, where it displaces the colon (Fig 1). The films of the small intestine again outline the mass that displaces the loops of intestine, but one is seen going straight through the mass, where the ulceration described in the report (Fig 2) is visible. It can be seen even better on the spot films, which also show slight dilatation of the jejunum proximal to the narrow ulcerative region.

DR SOWLES: This patient had symptoms of intestinal obstruction, although he had only one real attack. On admission, he had a low hemoglobin, a history of loss of weight and weakness. One immediately thinks of neoplasm of the right colon, in which the only presenting symptoms are sometimes anemia and loss of weight and weakness. As we go along in the history we find that the colon apparently was normal by barium enema whereas the small bowel showed a definite tumor in the jejunum—a large tumor with ulcerations of the mucous membrane. I think we can rule out carcinoma, which is quite rare in the jejunum, and does not

THE MEDICAL CENTER FOR CHILDREN AT THE CHILDREN'S HOSPITAL

The *Journal* notes with interest the recent announcement of the proposed expansion of the Children's Hospital leading to its transformation into the Medical Center for Children.

During its seventy-seven years of service the Children's Hospital has earned world-wide recognition for the quality of its medical and surgical work, for its research and for its training of medical students, physicians, nurses, physiotherapists and other workers especially interested in the problems of early life. To its wards have been brought young patients from all over New England and indeed from distant places, both in this country and overseas.

Its graduates are active in the practice of their specialties throughout the world.

The increased demands on the resources of the hospital, particularly from the New England area, the obsolescence of many of its buildings, and the opportunity for expansion of existing services and the creation of new units afforded by the constant effort of the staff to improve its work have led to the development of the Medical Center for Children. The heart of the plan, of course, is the Children's Hospital, with new and expanded facilities for the care of all aspects of disease in early life. To bring to older children, whose problems have long been neglected, all the medical, surgical and psychiatric assistance that will be available to younger patients, a new division of the Children's Hospital, a unit for adolescents, will be added. A neurologic institute, embracing the fields of neurology, neurosurgery and psychiatry, a greatly expanded infectious-disease division, with additional provisions for the care of patients with poliomyelitis, a cancer center and a greatly enlarged and completely equipped division of pediatric research form parts of the new plan. To assist in the most economical and efficient manner the doctors of New England who deal with young patients, a series of diagnostic clinics will be established. Similar facilities will be available in the several laboratory divisions that are designed to act as centers for consultation in chemical, clinicopathological, bacteriological and pathological aspects of pediatrics. In the field of preventive medicine, a health unit founded to bring to the problems of the healthy child from birth through adolescence all the specialized talent available in such a medical center should do much to raise the level of mental and physical health in New England and, in the course of time, to reduce the burden of disease.

To enable the Medical Center for Children to render the greatest possible service to the New England community, plans are now under way for appropriate affiliation with physicians and pediatric wards of general hospitals throughout this area, in extension of the unique relation that has existed for so long between the doctors in this region and the Children's Hospital. This affiliation, it is planned, will include not only arrangements for the

because one of the symptoms was the big mass in the abdomen, which disturbed the patient. The resection carried us into the pancreas and to the mid-colic artery. We thought it was unwise to go farther, in spite of the fact that tumor tissue appeared to

DR. SOWLES'S DIAGNOSIS

Lymphosarcoma of jejunum

ANATOMICAL DIAGNOSIS

Adenocarcinoma of jejunum

FIGURE 2 X-Ray Film of the Upper Jejunum
The arrow points to the ulceration in the jejunum

extend beyond that point. Because of the amount of mesentery that had to be removed it was necessary to resect the entire jejunum and to mobilize the third portion of the duodenum from beneath the ligament of Treitz. An end-to-end anastomosis was done between the duodenum and the ileum.

CLINICAL DIAGNOSIS

Carcinoma of jejunum

PATHOLOGICAL DISCUSSION

DR. MALLORY: This clinic today is a good example of what poor judgment it would sometimes be to make the correct diagnosis. The last case* should have been a benign tumor but proved to be a malignant one. This case showed a typical ulcerative carcinoma, which had extended very deeply into the mesentery and had also become adherent to and invaded an adjacent loop of small bowel.

*Case records of the Massachusetts General Hospital (Case 32211).
New Eng. J. Med. 234:701-703, 1946.

clinical use are the sodium and calcium salts of penicillin G

These findings alone are of considerable general interest. Other features of the chemistry of penicillin, more important perhaps to the chemist and pharmacologist than to the clinician, are also published for the first time According to the information thus far revealed it seems highly doubtful that synthetic penicillin will be forthcoming in the immediate future Even should such synthesis be accomplished in the laboratory, it does not follow that the large-scale production of synthetic penicillin would be economically feasible It is well known that the commercial manufacture of such simple substances as acetic and citric acids and various simple alcohols is best accomplished by fermentation methods, and the same may prove to be the case with penicillin

COMMENT

Diseases reported at figures above the seven-year median included chicken pox, bacillary dysentery, German measles, pulmonary tuberculosis and undulant fever Measles was also reported above the seven-year median, reaching a peak since 1906 that is second only to the record year of 1934 Reported at figures below the seven-year median were mumps, scarlet fever and whooping cough Record low figures were reported for lobar pneumonia The first case of animal rabies since February, 1944, was reported from the central part of the Commonwealth The animal was a recent arrival from a nearby state

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from Deerfield, 1, Springfield, 1, total, 2 Diphtheria was reported from Andover, 1, Arlington, 1, Boston, 5, Chelsea, 1, Cushing General Hospital, 1, Falmouth, 2, Haverhill, 1, Malden, 1, Millville, 1, Taunton, 1, West Newbury, 1, total, 16 Dysentery, bacillary, was reported from Belmont, 1, Boston, 2, Cambridge, 3, Lowell, 1, Peabody, 1, Wrentham (State School), 2, total, 10 Encephalitis was reported from Chatham, 1, total, 1 Malaria was reported from Amherst, 1, Boston, 8, Cambridge, 1, Chelsea, 1, Fall River, 2, Gardner, 1, Haverhill, 1, Hingham, 1, Lawrence, 1, Lynn, 1, Nantucket, 1, New Bedford, 1, Peabody, 1, Salem, 1, Southbridge, 1, Stoughton, 1, Waltham Regional Hospital, 2, Warren, 2, West Springfield, 1, Woburn, 1, Worcester, 5, total, 35 Meningitis, meningococcal, was reported from Boston, 4, Fall River, 1, Lee, 1, Ludlow, 1, Malden, 1, Medford, 1, Millbury, 1, Quincy, 1, Salem, 1, Wayland, 1, Worcester, 1, total, 14

Meningitis, Pfeiffer bacillus, was reported from Cohasset, 1, Haverhill, 1, Saugus, 1, total, 3 Meningitis, pneumococcal, was reported from Abington, 1, Brockton, 1, Gloucester, 1, Natick, 1, Pittsfield, 1, total, 5 Meningitis, other forms, was reported from Boston, 2, total, 2 Meningitis, undetermined, was reported from Dalton, 1, Framingham, 1, North Adams, 1, Springfield, 1, total, 4 Salmonella infections were reported from Malden, 1, Northampton, 1, Springfield, 1, total, 3 Septic sore throat was reported from Arlington, 1, Belmont, 1, Boston, 4, Everett, 1, Greenfield, 1, Haverhill, 1, Newton, 2, Norfolk, 1, Westford, 2, Weston, 1, total, 15 Tetanus was reported from Pittsfield, 1, total, 1 Trichinosis was reported from Adams, 1, Boston, 4, total, 5 Typhoid fever was reported from Boston, 1, Chicopee, 1, Waltham, 1, total, 3 Undulant fever was reported from Belmont, 1, Boston, 1, Deerfield, 1, North Andover, 1, Oxford, 1, Quincy, 1, Southbridge, 1, Tewksbury, 1, Yarmouth, 1, total, 9

REPORT OF MEETING

NEW ENGLAND ROENTGEN RAY SOCIETY

The New England Roentgen Ray Society held its last meeting of the season on Friday, May 17, 1946 The following officers were elected for the ensuing year president Dr Samuel A. Robins, vice-president Dr Stanley A. Wilson, secretary Dr George Levene The second George W. Holmes Annual Lecture was delivered by Dr Arthur C. Christie, of Washington, D. C. Dr Christie's subject was "The First Fifty Years of Radiology The elements which have contributed to its growth as a great medical specialty" Dr George W. Holmes and Dr Christie were presented with the Society's silver colonial pitcher, which is emblematic of the occasion Dr Holmes received congratulatory telegrams from his former students in various parts of the country

care of specialized medical and surgical cases but also provision for the training and postgraduate education of practicing physicians, interns, nurses and other workers with special interest in pediatrics

The essence of the Medical Center for Children is the gathering under one roof, for a combined attack on the manifold problems of health and disease of the infant, the child and the adolescent, doctors and medical workers whose major interests concern these age groups, with the aid of all the technics and specialized knowledge available in the medical world today

The long history of distinguished contributions of the Children's Hospital to the various medical, surgical and laboratory aspects of disease of infancy and childhood is a guarantee of the success of this ambitious but wholly logical and practical plan. The *Journal* extends its best wishes to the Board of Trustees and to the Medical Staff of the Children's Hospital in their great undertaking

CHEMISTRY OF PENICILLIN

IN SHARP contrast to the many useful functions performed during the war by Government-supported research, there was at least one undesirable feature of that program, namely, the withholding of newly acquired information. The chief purpose of that secrecy—to keep from the enemy all information that may give him aid and comfort—is quite understandable. On the other hand, this policy has often served to channel information within a relatively small group of workers and away from others, perhaps of equal competence, who might have put that information to good use. The disadvantages and dangers of this sort of secrecy and the importance of the freedom to publish the results of scientific research are well recognized, and a vigorous attempt to preserve that freedom in any program of federally supported research is being made by a number of leading scientists

Now that the war is over, there is still a good deal of scientific information that is being considered as "secret" or "classified" and is not yet published or otherwise freely available. Although there may be some justification for this attitude in matters of

immediate national defense, such as those involved in the methods of manufacturing atomic bombs, many facts concerned with health are also included. Some of the latter information is gradually coming to light. Because of the vast amount of research and the colossal number of papers that are undoubtedly available for publication on certain subjects, the Committee on Medical Research and other similar bodies have wisely adopted the policy of summarizing the results of research in certain vital fields in advance of the publication of the detailed results

One of the first of these summaries concerns the chemistry of penicillin.* Many of the most outstanding among the research laboratories in the United States and Great Britain participated in the program. Although the exact structural formula of penicillin is still undetermined, and its synthesis has not yet been accomplished, some of the most significant aspects of its chemistry have been determined beyond reasonable doubt.

Previously published reports had indicated that several forms of penicillin exist, each of which may be derived from cultures of the same strain of *Penicillium*. The usual form is penicillin G, which is the chief active ingredient of the commercial preparations now available. In addition, penicillin X has been described, and limited experimental and clinical studies of its use have been made in this country. Another form, penicillin F, has also been recognized in this country and in Great Britain. According to the joint report by the Office of Scientific Research and Development and by the Medical Research Committee of Great Britain, the forms of penicillin known as F, G and X in this country and as I, II and III, respectively, in Great Britain, as well as a new form, K-penicillin, all have the empirical formula $C_{14}H_{18}O_4SN_2R$. The differences depend on the structure of R. In penicillins G and X, for example, the structures of R are quite closely related, being benzyl in the former and para-hydroxybenzyl in the latter. Each different form can, of course, be made into various metallic salts or esters. The varieties of penicillin in general

NUTRITION AND THE WAR*

JOHN B. YOUMAN, M.D.†

NASHVILLE, TENNESSEE

IT IS a distinct honor to be invited to give the Shattuck Lecture, with its long list of distinguished former lecturers and its tradition of excellence of the addresses. I therefore appreciate greatly this honor that has come to me and the opportunity to address the Massachusetts Medical Society on this occasion.

So far as the practice of medicine is concerned, the title of my lecture is somewhat of a misnomer, because the direct contribution of the war to clinical nutrition was not very great. Actual nutritional-deficiency disease was not common in the troops. Most of the actual work in nutrition was in the field of preventive medicine and was not concerned with nutritional disease in the individual patient. Even among prisoners of war and civilian populations, study and observation added little to our knowledge of the severer forms of these diseases. There were, as we shall see, examples of some unusual manifestations of deficiencies. The absence of certain anticipated deficiencies was noteworthy. In Europe particularly the preponderance of caloric and protein deficiency and the rarity of vitamin deficiencies in the civilian populations were striking. But aside from these observations little that is new was obtained from direct observation. The war did, however, intensify interest and speed up research in nutrition. As a result so much has been done that the end of hostilities provides a useful point at which to pause, survey what has been done and consider the place of some of this new knowledge of nutrition in the practice of medicine.

* * *

There are many aspects of nutrition, but those with which the physician is primarily interested are the prevention of nutritional-deficiency disease and its diagnosis and treatment. Ordinarily the physician's interest in the general prevention of nutritional-deficiency disease is rather academic un-

less he happens to be a public-health officer. The private practitioner does have, however, a very real personal interest in this aspect of nutrition, and if he is alert he will maintain a general acquaintance in this field. It is from the general population that his patients are drawn, and the background of nutrition of that population may influence very considerably the nature of the illnesses of his patients, their reaction to disease and their response to his treatment. To some extent this interest, indeed this self-interest, has been appreciated by pediatricians and by a few other physicians, but in general it has not received the attention it deserves. In contrast to general prevention, the prevention of nutritional-deficiency disease in individual patients is of much greater immediate importance to the practicing physician — a problem with which he must deal every day and in some degree or other with almost every patient.

Existing nutritional-deficiency disease is encountered by the doctor in two forms. One is an idiopathic or primary disease caused by a dietary inadequacy, often the result of socioeconomic factors over which the patient may or may not have some control. The other is a conditioned disease in which the deficiency is dependent on some other illness that causes a nutritional deficiency or permits it to develop. The illnesses or abnormalities that cause or induce the deficiency are of the most varied kinds, ranging from severe organic gastrointestinal disease to mild psychoneurosis. This is the kind of nutritional deficiency disease that will be encountered oftenest by the practicing physician and is of the greatest immediate importance to him. It is also the kind that he should be most alert and active to prevent, the more so because such deficiency disease may be the direct result of things he does or fails to do, things directly subject to his control. Often they are relatively simple things, and often failure to control them has a very significant effect on the patient.

There are certain differences between the idiopathic and conditioned type of disease in relation to prevention and treatment. Idiopathic deficiencies ordinarily exist before the patient goes to the doctor. Either they are the disease for which the

†Professor of Medicine, Vanderbilt University School of Medicine, Director, Postgraduate Training for Veterans, visiting physician to Vanderbilt University Hospital.

BOOK REVIEWS

Medical Gynecology By James C Janney, M D 8°, cloth, 389 pp, with 97 illustrations Philadelphia W B Saunders Company, 1945 \$5 00

There have been those who say, "There is no such thing as medical gynecology." It is therefore all the more gratifying that an author of Dr Janney's distinction should devote his new volume to medical office gynecology. It has developed largely from his experience in clinical teaching for the past quarter century, and aims to aid the student in correlating his didactic lectures with his experience in the gynecologic clinic and to provide refresher material for the general practitioner. It follows the standard pattern of other texts—history and examination, symptoms, physical findings, laboratory tests and special examinations, and gynecologic treatments of a medical nature. There are chapters dealing with certain controversial subjects, such as abortion, contraception, illegitimacy and sterilization. Finally, there is an admirable brief section on the alternatives of radiation or surgery in the treatment of gynecologic malignant tumors and of intractable uterine hemorrhage of nonmalignant origin. The book is illustrated with well-chosen cuts and has a classified select bibliography of forty-one titles.

Trauma in Internal Diseases With consideration of experimental pathology and medicolegal aspects By Rudolf A Stern, M D With a foreword by Francis C Wood, M D 8°, cloth, 575 pp New York Grune and Stratton, 1945 \$6 75

It is a generally accepted principle of modern society that the workman injured through no fault of his own during the performance of his labors is entitled to compensation. The application of this principle is easy when the trauma is obvious, as, for example, when a fracture is sustained, but can be extremely difficult in the so-called "internal diseases." The wisdom of Solomon often could not decide the degree of aggravation of a duodenal ulcer resulting from employment in a certain occupation. In such cases it is the duty of the physician to advise and enlighten the court.

Those members of the profession who find themselves even occasionally on the witness stand will find this book invaluable. The author has thoroughly reviewed diseases of the heart, lungs, kidneys, gastrointestinal tract, endocrine glands and blood with regard to the role of trauma in etiology or aggravation. Some two thousand sources are listed in the bibliography. Most of these are references to cases that have been decided in court, and it is quite possible that this book will prove to be as useful to the lawyer as to the doctor.

American Red Cross First Aid Textbook 12°, paper, 254 pp, with 264 illustrations Philadelphia The Blakiston Company, 1945 Sixty cents

This book has been completely revised, with new illustrations and a rewritten text. It was prepared with great care under the direction of the Committee of Surgery, Division of Medical Sciences, National Research Council. In addition to revision of the chapters on surgery, the medical director of the American Red Cross and his staff fully revised the sections on first aid, water safety and accident prevention. Special chapters were contributed by authorities on injuries to the eye and on snake and other animal bites. The revision is by far the most complete since the book was first published in 1909, and with its splendid illustrations, clear text and adequate index, this volume should become a valuable adjunct to the work of the American Red Cross. In addition, it should appeal to the medical profession and should be in the hands of every first-year medical student. It will find a fitting place in many homes and factories. Every police officer and other public official who has to deal with acute emergencies should be thoroughly familiar with the contents of this book.

Mass Radiography of the Chest By Herman E Hilleboe, M D, and Russell H Morgan, M D 12°, cloth, 288 pp, with 93 illustrations Chicago The Year Book Publishers, Incorporated, \$3 50

One of the chief medical dividends of the late war was the vast experience in mass radiography of the chest. This

monograph by two outstanding authorities on that subject is of timely interest and value, as the experiences and technique learned in the induction centers and service installations will undoubtedly be spread to large portions of the civilian population. This manual, as it may properly be called, was prepared for just such use, and it brings together the accumulated information on objectives, planning, equipment and technique, as well as valuable experiences in the procedures necessary to successful surveys of large numbers of people.

The authors lean over backward in the attempt to avoid the charge that such surveys may be interpreted as diagnostic examinations. Many of the common diseases and conditions involving the chest, heart and lungs can be identified quite accurately by the small-film technic. Quite correctly, however, they emphasize throughout the book the fact that their methods are primarily for screening purposes and that detailed clinical studies may be necessary in the positive and doubtful or borderline cases.

The chapter "Roentgen Diagnosis of the Chest" is particularly conservative and might well have been omitted, except that there is no similar primer for the uninitiated, it is to be hoped most sincerely, however, that the untrained will not attempt such an important public-health function.

This manual is of particular value to public-health officers, tuberculosis-control organizations, radiologists and all who are interested in the maximum efficiency and return from public-health expenditures.

NOTICES

ANNOUNCEMENTS

Dr Warren D Babb, having returned from military service, has resumed the practice of internal medicine at 40 Chestnut Street, Salem.

Dr Samuel Bolan announces his return from service with the United States Navy and the reopening of his office at 555 High Street, West Medford.

Mr William S Brines took over the position of administrator of the Malden Hospital, Malden, on June 1.

Dr Sidney C Dalrymple, having been released from active duty with the Navy, announces the opening of an office for the practice of medicine at Middle Dyke Farm, Georgetown, Maine.

Drs Channing Frothingham, George P Denny and Victor G Balboni announce the opening of offices for the practice of internal medicine at 101 Bay State Road, Boston.

Dr Luke Gillespie, having been released from military service, has returned to the practice of obstetrics and gynecology at 1180 Beacon Street, Brookline.

Dr Alfred M Glickman announces his return from service with the United States Navy and the reopening of his office at 95 State Street, Springfield, for the practice of surgery.

Dr Elwood O Horne, having recently returned from military service, announces the opening of his office for the practice of general surgery at 36 Pleasant Street, Worcester.

Dr Charles Schlosberg announces his return from military service and the resumption of pediatric practice at 483 Beacon Street, Boston.

Dr Leslie H Van Raalte announces the resumption of private practice limited to gynecology and obstetrics at 15 Lincoln Avenue, Wollaston.

(Notices continued on page xix)

is usually a negative calorie balance, which increases the deficiency of nitrogen (protein)

This phenomenon persists for a variable length of time and exists to a variable degree, depending on factors to be discussed later. If it is severe enough and of long enough duration, the body reserves of protein are exhausted and actual protein deficiency disease develops as I have described. This is responsible for the loss of weight, muscle atrophy, weakness and other effects of such an illness.

This phase, which is often spoken of as the catabolic phase of the reaction to injury or disease, may last for weeks, and is succeeded by an anabolic phase, during which the nitrogen balance becomes positive, nitrogen is retained and protein formed, tissues are restored, and weight is regained. It corresponds to the period of convalescence and recovery.

Besides fractures, this abnormality occurs in a wide variety of other injury and disease — in severe burns, after major surgical operations, especially those in which the peritoneum is opened, with infections such as osteomyelitis and abscesses and with some infectious diseases, such as typhoid fever and meningitis. The cause of this metabolic and nutritional disturbance is not clearly known. There is some evidence that it is linked to the adrenal glands and perhaps to other endocrines. It is a positive, independent reaction not related solely to deficiency intake, although intensified by the latter as we shall see. Usually the negative balance continues despite an increase in nitrogen intake, excretion increasing with intake, and in some cases, despite exceedingly large intakes of protein, this negative nitrogen balance cannot be overcome. Because of this and because of its essential nature it has been thought by some to represent a beneficial or protective reaction to injury and disease that should not be overcome.

This specific or essential negative nitrogen balance is exaggerated by a number of other factors that are very important in producing the clinical state of deficiency disease. Following the injury, or with the onset of the disease, there is usually a loss of appetite and a resultant decrease in the intake of food and hence of calories and protein. To this specific loss of appetite there are often added the factors of unappetizing meals, poorly prepared and served, weakness, difficulties brought about by recumbency or by complicated apparatus, nausea and vomiting and the mental changes of illness, all of which interfere with the intake of food. Unfortunately to these must often be added indifference on the part of the doctor and nurse to problems of nutrition, and even misconception and ignorance regarding proper diet and nutrient requirements. The importance of those factors is shown by the results of a survey of food consumption in Canadian military hospitals.² This revealed such disparities as a decrease in a diet from about 4000 calories and 156 gm of protein as planned to 2600 calories

and 75 gm of protein as actually served, with a further reduction to 1850 calories and 54 gm of protein actually eaten. Similar studies in one of our own military hospitals revealed high-carbohydrate, low-fat diets for convalescents containing as little as 1400 to 1600 calories and actual intakes as low as 800 calories.³

Besides these deficiencies of intake there are other secondary factors affecting nitrogen loss of even greater importance. Although in the primary reaction the nitrogen is lost mainly by urinary excretion, there is often a large added loss in exudates, drainage from wounds and from the surface of burns and even in the sputum and gastric contents and, in those cases with albuminuria, an added loss through the kidneys. Often these losses are tremendous. Thus the specific and primary defect is greatly exaggerated and the nutritional deficiency increased. In diseases not associated with this specific metabolic disorder a nitrogen and protein loss can, of course, occur as the result of simply a dietary deficiency, leading to the same protein-deficiency disease.

The effect of this negative calorie and protein balance depends on its severity and duration and on the nutritional state of the patient. If it is mild and of short duration in a well nourished person, little harm is done. The body has sufficient reserves of protein and body fat to tide him over. To say that in such cases nutritional deficiency disease exists would be incorrect. What has occurred is a metabolic disturbance or abnormality. However, if the reaction is severer and more prolonged, or if it occurs in patients with inadequate reserve of these nutrients, actual deficiency disease does occur. Curiously, if the patient is already much undernourished, the primary, specific negative nitrogen balance does not occur or is of slight degree, as though the body were incapable of responding to an injury or disease in the normal manner. However, reflection will show that under these circumstances the body is already in a state comparable to that reached in the latter stages of the catabolic phase of the reaction, and that nutritional disease already exists.

In addition to the initial reaction, similar, though usually less severe, reactions may occur as the result of complications during the course of the illness. Thus the changing of casts, secondary operations, the opening of abscesses and the occurrence of a secondary or complicating infection or infectious disease may all be accompanied by a return or exaggeration of the nitrogen deficit and of the nutritional-deficiency disease.

The outward manifestation of this deficiency disease is a loss of body weight. At first slight and representing mostly loss of fat, when more severe and continued there is loss of tissue protein, revealed externally by atrophy of muscles. There is, however, also a loss of native protein, from important parenchymatous organs and from the blood plasma.

patient seeks relief, or they are a substratum to which is added whatever other disease the patient may acquire. Conditioned deficiency diseases, on the other hand, are developed subsequent to some other illness. Although often present by the time the doctor first sees the patient, in many cases, especially those associated with acute illness and trauma, they do not occur until after the conditioning disease begins. This gives the doctor opportunity to prevent or minimize them. In conditioned deficiency, then, the opportunity for prevention is greater. In the idiopathic disease, diagnosis and treatment of an existing deficiency is the problem.

At the present time the principal nutritional deficiency diseases that can be diagnosed and are considered to be of clinical significance in man are caused by a lack of the necessary amounts of the following substances: calories, protein, vitamin A, thiamin, niacin, riboflavin, folic acid (*L. casei* factor), ascorbic acid or vitamin C, vitamin K, iron and calcium. There are others, notably those of water and sodium chloride, and perhaps some of the other electrolytes, that we can recognize clinically. Some would add vitamin E, certain of the so-called "trace elements" and perhaps others of the vitamin B complex. But these are not yet well enough established, if indeed they exist, as recognizable clinical disease to warrant inclusion here.

From these I have selected for discussion those that at present seem to be of considerable importance to clinical medicine, or about which there is new and interesting knowledge. However, before proceeding with that discussion I wish to clarify the use and meaning of certain terms. The term "nutritional deficiency" has two meanings depending on whether one is referring to a deficiency in the dietary, or the intake of food, or whether one is referring to the state of nutrition of the body. In health the body possesses a reserve of nutrients. Therefore, it is possible for a dietary nutritional deficiency to exist without a state of nutritional deficiency in the body. Only when a pathologic change in structure or function has occurred can we speak of nutritional-deficiency disease. Clear understanding and attention to this relation will prevent much confusion and misunderstanding.

* * *

Two nutritional factors that have assumed a new and important place in clinical medicine during the war are the energy principle (calories) and protein. In 1897, just about fifty years ago, Dr. Frederick C. Shattuck¹ wrote a paper, "Diet in Typhoid Fever," in which he advocated the use of relatively large amounts of food in this disease. Although he lacked a knowledge of all the underlying biochemical processes that demand such treatment, his practice was sound and represents for most practical purposes the recently developed concepts of nutrition in relation to injury and disease.

Simple, idiopathic calorie-and-protein-deficiency disease is not ordinarily seen by physicians. On the contrary, conditioned deficiency of these factors is one of the most frequent, perhaps the most frequent, of all the nutritional deficiencies seen in practice. Yet far too little attention has been paid to them despite the existence for many years of the example of typhoid fever. Here, a severe infectious disease, with a long, debilitating course, a relatively high mortality and a prolonged convalescence, was converted into a much less severe, less fatal illness during which patients often gained weight, maintained good general condition and recovered more quickly by the simple provision of an adequate calorie diet. Why the medical profession, with this experience before its eyes, has been willing to accept the severe weight losses and debility accompanying other infectious diseases and illnesses as a natural and inescapable concomitant of those diseases is rather incomprehensible.

Although it is customary to distinguish between calorie and protein deficiency, I should like to present the thesis that, so far as disease is concerned there is only a deficiency of protein and that for all practical purposes starvation, aside from lack of vitamins and minerals, is protein starvation. Under ordinary circumstances a healthy person possesses some slight reserve of carbohydrate (glycogen) and a considerable reserve of fat, amounting roughly to 10 per cent of the body weight, sometimes much more. When there is a dietary deficiency of calories this reserve is drawn on and used for energy (calories). Only when the fat is all or nearly all gone does the draft on tissue protein begin, and only when this exceeds a certain as yet indefinite point does actual nutritional deficiency disease begin. Under some conditions, as we shall see, there may be a direct loss of tissue protein without reference to calorie levels. When, however, calories are inadequate this loss is increased.

Recent studies, especially those conducted during the war, have provided much new knowledge about this deficiency and emphasized its importance as a frequent and serious complication of a variety of diseases, ranging from certain kinds of trauma and injury to infections and infectious diseases. The circumstances and nature of the deficiency are as follows. Many kinds of injury and disease are accompanied by a negative nitrogen balance. This means that more nitrogen is excreted than is taken into the body in the form of protein. Even so simple a restriction as confinement in bed may produce this effect. The most striking and uncomplicated examples are seen in fractures of the large bones in previously healthy and well nourished persons. Under these circumstances the negative nitrogen balance stands out as a sharply defined abnormality clearly related to the acute injury and without any background of other disease or apparent cause. Accompanying the negative nitrogen balance there

and calorie deficit can be anticipated. This should be met by nitrogen and calorie intakes to overcome or minimize these deficiencies. Standardized regimes are useful, but mainly to indicate the amount and kind of food and route of administration. They will not assure its consumption. Varco⁵ has recently published a number of excellent diets for this purpose in a variety of surgical conditions. In general, 3000 to 5000 calories and 120 to 150 gm of protein are necessary and advisable. As has already been said, experience has shown that in many cases it is not necessary or desirable to secure complete nitrogen equilibrium during the early and more marked stage of the catabolic reaction, the disadvantages and untoward results of attempting to supply huge amounts of protein outweighing the advantages. However, sufficient protein and calories should be administered to provide a high intake of nitrogen, overcome the calorie deficit and take full advantage of the beginning of the anabolic period, which will probably be hastened by this treatment.

When possible, this nourishment should be provided as ordinary food, supplemented when necessary by special feedings. Such supplemental feedings will be required in most cases. In general an attempt should be made to secure an intake of around 2500 calories and 90 to 100 gm of protein by ordinary meals. The need for care in preparation and serving of the food and for assistance to the patient in eating is very great, and on this depends much of the success of the procedure. Fortunately, after an adequate or satisfactory intake has been secured for a few days the appetite generally improves and many patients will voluntarily consume large quantities of food.

The additional requirements are met by supplements. These are most satisfactorily furnished as milk drinks, composed of milk with added skim-milk powder, or prepared casein, and glucose. A variety of satisfactory formulas have been devised. A typical one provides 28 gm of protein and 343 calories for each 240 cc. Therefore, three such feedings will add 84 gm of protein and 1029 calories a day, bringing the daily intake to over 3500 calories and 160-180 gm of protein if the regular meals are consumed. Special recipes for other high-protein foods developed by the Medical Dietetic Division of the Army's Medical Nutrition Laboratory⁶ are helpful in securing a high intake of protein.

The simplest guide in the management of these patients is loss of weight, which, except for the complication of edema, is quite a sensitive index of the state of protein nutrition. In general, it may be assumed that losses of more than 10 per cent below the ideal calculated weight are evidence of actual protein deficiency. However, in obese persons protein loss may occur before calorie deficiency and weight loss are apparent. Many patients are, of course, over their ideal weight and can tolerate larger losses of their actual weight so far as fat is

concerned. The metabolism of large amounts of fat, however, increases considerably the work of the liver, and in some circumstances, especially those in which there may be injury to the liver, this may not be desirable. This is particularly true in view of the recent evidence of the greater susceptibility of the liver to injury in conditions of protein deficiency.

Accurate nitrogen-balance studies are not often needed in these patients. A careful record of intake — calories and nitrogen — should be maintained in such patients, and it can be assumed that if intakes of around 3500 to 4000 calories and 120 to 150 gm of protein are secured the nitrogen deficit will be abolished or minimized in most cases. Losses beyond about 10 per cent of calculated ideal body weight should be avoided, and if losses exceed this figure a more careful determination of the nitrogen balance should be made. In burned patients, particularly, and in those with exudates, draining sinuses, dysentery and other causes of abnormal loss of protein, a careful check of the probable balance must be made to determine the necessary intake, which in some cases may be unusually large. For instance, it has been calculated that an average-sized man with a third-degree burn of 50 per cent of his body surface may lose as much as 199 gm of nitrogen in twenty-four hours from the burned surface, equivalent to 124 gm of protein. To replace this loss requires 600 gm of meat, or about 2000 cc of plasma, and the amount estimated to be necessary to put some patients in nitrogen equilibrium has been calculated to be as much as 2000 gm of meat, or 23 units of plasma.⁷

Particular attention must be paid to edema because of its nutritional significance and because it masks an actual loss of tissue. Retention of 10 pounds of water can occur without visible edema. Except in patients with complicating renal or cardiac disease, the edema is nearly always related to hypoproteinemia, which can be detected by determining the concentration of the plasma proteins. Ordinarily the determination of the total serum proteins by the simple specific-gravity methods suffices as a general guide, but the greater significance of the albumin and the possibility that albumin is depressed while total protein remains normal or near normal make it necessary to determine serum-protein fractions when such a condition is suspected.

With patients who are already in a state of nutritional-deficiency disease, more strenuous treatment is necessary because the problem is one of replacement rather than prevention — the replacement of losses rather than maintenance of reserves. Furthermore, speed is highly desirable, and delay merely prolongs recovery and convalescence. Weight, with due consideration for edema, is again the best general evidence of the state of protein nutrition and the loss of protein from the tissues.

These changes have recently been carefully studied experimentally by Keys and his associates.⁴ Keys's subjects had only simple protein deficiency, but the effects so far as loss of protein from the tissues and organs is concerned are basically similar to those seen accompanying injury and disease with a primary negative nitrogen balance. In Keys's experiment previously healthy men were given about half the calories they expended daily, a regime designed to reduce their weight by about 25 per cent in a few months. In these subjects, in addition to the severe loss of weight, muscle atrophy, weakness and mental changes, there occurred edema, great atrophy of such viscera as the heart and physiologic changes, such as severe hypothermia, bradycardia and lowered basal metabolism.

In patients with injury or disease many of these abnormalities are even severer. Others are masked or modified, and not necessarily in a favorable way, by various factors not present in simple starvation. For instance, fever and infection prevent bradycardia and maintain or elevate the basal metabolism. The weakened heart may be enlarged instead of smaller. Edema is often greater and more dependent on hypoproteinemia. In Keys's cases the edema failed to show a close relation to plasma protein levels, and it is probable that other factors were concerned in its production, the likeliest one in my opinion being loss of tissue pressure resulting from the rapid and severe loss of weight. In patients, on the other hand, the nutritional edema is usually associated with a hypoproteinemia, often severe.

These, then, are the changes and the cause of the changes that produce much of the picture of serious illness so well known to physicians. They increase mortality, increase morbidity, predispose to complications, prolong the course of illness and delay convalescence and recovery. If they can be prevented or relieved, the course of disease becomes shorter and less severe, complications fewer, and the outcome more favorable. Reference has already been made to the possibility that the negative nitrogen balance occurring in injury and disease constitutes a protective and favorable reaction, and that therefore it may be inadvisable to suppress or abolish it. This is possibly true, and the difficulty or even impossibility of overcoming the negative balance early in the catabolic phase, nitrogen being excreted as fast as it is taken in, supports such a concept. Nevertheless there are many examples of reactions to disease, primarily beneficial, that when excessive become harmful and retard recovery. It seems improbable that protein losses to the point of severe weakness, muscle atrophy and hypoproteinemia can be beneficial, and experience suggests that measures to relieve, if not completely abolish, this reaction shorten it, hasten and strengthen the phase of recovery and prevent or minimize the untoward

effects of this reaction. Much attention is being paid at the present time to early ambulation, but early ambulation is useless, or even harmful or impossible, unless a proper state of nutrition is maintained or secured.

From this discussion it is apparent that in practice there are two stages of this reaction that can be rather sharply differentiated and that differ in their practical management. The first is the initial period when only the metabolic disturbance is present and no nutritional-deficiency disease has occurred. When the patient is seen in this stage there is the possibility of preventing or minimizing serious effects. The second is the stage when a greater or lesser deficiency has developed. In many cases this condition has developed under the eyes of the physician, and either it is ignored or the more difficult process of treatment rather than prevention is attempted.

As for the practical management of this problem and the maintenance or restoration of the proper nutritional state, I fear I must promise you Churchill's prospect of "blood, sweat and tears." Most of you, if you make an honest attempt to secure the benefits of such a regime, will sweat blood and weep tears. The principle is simple and easy. No difficult, highly specialized or expensive techniques or materials are necessary. But perhaps because of this, and because it does require close attention and supervision on the part of the physician and the nursing and other staffs, as well as the wholehearted co-operation of the patient, in the drab day-by-day business of getting food into the patient, it is a difficult problem. That it *can* be solved is shown by the success in the modern treatment of typhoid fever.

Much help can be derived from the use of standardized procedures or "routines," particularly in a hospital. However, as always, each patient will present an individual problem, his requirements will differ as will his response, and he will need individual attention. Routines can provide only the basic framework of the procedure, within which adjustments must be made for each patient.

A patient when seen by the physician should have an appraisal of the state of nutrition, the probable effects of the disease on his nutrition and what is needed for the prevention or treatment of nutritional disease. Often this will require only the usual history, physical examination and routine laboratory work, but special laboratory tests may be needed. For the patient who is injured or develops an illness in a normal state of nutrition, the need can be determined in general from the nature of the illness and its severity and probable duration, but complications and variations in the response of the patient and his co-operation may require modification from time to time. For instance, in fractures of the large bones, or severe trauma, in serious burns and in most major surgical operations for acute diseases, an immediate negative nitrogen balance

women who have failed to establish an adequate reserve during pregnancy, or who have even suffered from an actual protein deficiency, this additional protein loss may be a serious drain

Recent studies indicate a close relation between nutrition, particularly protein nutrition, and the toxemias of pregnancy. For example, Tompkins⁹ found four times as many toxemias of pregnancy in a group of women with dietaries limited in protein as in those on a diet containing 110 gm of protein daily, five times as many with edema, and eight times as many with pre-eclampsia. In 1400 pregnant women Holmes¹⁰ found twice as many with toxemias of pregnancy in those with protein intakes of 60 to 70 gm as among those with intakes of 110 to 120 gm. Edema is much oftener due to protein deficiency and hypoproteinemia than to renal or cardiac disease, and some cases of the anemia of pregnancy may have the same cause. Thus, the greater need for protein during pregnancy and the harmful effects of an actual protein deficiency require that protein be furnished in larger amounts at this time. Intakes of at least 1.5 gm per kilogram of body weight should be provided, and somewhat larger amounts are probably desirable. During lactation the intake should equal 2 gm per kilogram.

Two other aspects of protein nutrition of clinical importance in both primary and conditioned deficiency disease received attention during the war. One is the relation of protein to the formation of immune bodies. These substances, which are of vital importance in resistance to infectious disease, are contained in the gamma-globulin fraction of the serum proteins and are elaborated by the globulin-producing cells of the liver and reticuloendothelial tissue. In their formation protein is required, and moreover protein containing the essential amino acids. When the amount of such protein in the diet is inadequate, it can be derived for a time from the body tissues. But, when actual protein deficiency occurs and atrophy of the tissues ensues, production of the immune bodies becomes inadequate. Even the production and activity of the phagocytes is impaired, and this second defense against infection is weakened.¹¹

The other aspect of protein nutrition is the action of the specific amino acids. Since some ten of the amino acids cannot be synthesized by the body and must be obtained in the food or some other exogenous source, it is obvious that deficiencies of these nutrients must occur. As yet, however, there is no known recognizable clinical expression of such deficiencies. We do know, however, that unless these amino acids are present in adequate amounts it is impossible to maintain nitrogen equilibrium, and there is a loss of nitrogen from the body that probably represents the breakdown of some body protein to supply the amino acid for a more essential purpose. Thus there occurs again a loss of protein from the tissues, which, if great enough and long enough

continued, must result in protein deficiency. Therefore it is necessary, in applying protein to prevent or relieve protein deficiencies, to provide protein containing adequate amounts of the essential amino acids.

It is also known that certain amino acids, notably methionine, are utilized in certain processes in the liver concerned with detoxification and that an adequate supply of protein containing such amino acids probably protects the liver against injury in certain endogenous and exogenous intoxications, such as anesthesia,¹² as well as against the effect of certain diseases, such as infectious hepatitis. This protective action fails or is inadequate in cases of protein deficiency.

* * *

Turning now to the vitamins, deficiencies of vitamin A are often neglected in medical practice because of the rarity of xerophthalmia, outspoken night blindness or a severe dermatosis. Perhaps the erroneous concept of vitamin A as the anti-infective vitamin has given it a bad name among doctors. Vitamin A is not per se anti-infective. However, vitamin A deficiency is fairly frequent. Although in a recent review it is stated that it is probably infrequent in this country,¹³ a report from Holland in the following issue of the same journal refers to it as the only vitamin deficiency that was observed in a great number of children.¹⁴ It is the only vitamin deficiency, aside from rickets, commonly seen in Germany and Austria at the present time and has been rather prominent in France, Spain and other European countries. Although the signs and symptoms of the deficiency are not specific, they are suggestive and can be supported by determination of vitamin A concentration in the blood. Distinctly low values for the latter, in the absence of temporary causes, can be considered indicative of vitamin A deficiency from a practical clinical point of view.

Vitamin A is particularly important in pregnancy. The child is dependent on the mother for its supply, and the drop in blood vitamin A seen in the latter months of pregnancy¹⁵ may represent in part the transfer from mother to child. If the mother's supply is low, she may deplete her own store and yet fail to furnish the infant with a sufficient store. When breast fed, the child is dependent on the mother's milk for an increase in its store of vitamin A, which is normally less than that of adults, gradually increasing as the child grows. An inadequate endowment may fail to be improved or even maintained if the child receives an inadequate postpartum supply from its mother, a serious deficiency because vitamin A is important in the growth of children. Fortunately, the widespread use of fish-oil supplements in this country, mainly to prevent rickets, tends to prevent greater deficiency of vitamin A among our children, an important reason for

Muscular atrophy supports this finding. Hypoproteinemia indicates the cause of edema, and its degree is a rough index of the degree of protein loss and atrophy of the other body tissues and organs as well as of the plasma. Intakes as high as 5000 to 6000 calories or higher and 200 to 300 gm. of protein may be required and very effective, although often somewhat smaller amounts suffice.

In patients with nutritional disease already established and in some other circumstances, the ordinary intake of food by mouth proves inadequate and parenteral feeding may be necessary. It may also be necessary in delirious or mentally ill patients, in those with disease of the gastrointestinal tract, especially as a preoperative procedure when haste is necessary or desirable, and for those who do not co-operate by ingesting adequate amounts of food. Ordinarily, parenteral feeding is best accomplished by stomach or duodenal tube, which can be used intermittently or for a continuous drip. For this purpose a variety of formulas for liquid foods are available, most of them similar to those used for supplemental feeding by mouth. There is, however, one valuable and notable addition—solutions of amino acids. These preparations, although very unpleasant when taken by mouth, are well tolerated if given by gastric or duodenal tube, are very efficient in replacing protein and make it possible to introduce large amounts of nitrogen with relative ease. Only solutions known to be satisfactory and capable of maintaining nitrogen balance when constituting the only source of nitrogen should be used.

In some cases it may be necessary to use intravenous feeding, alone or in combination with gastric or duodenal gavage. Ordinarily such intravenous feeding is only for replacement of nutrients lost acutely, such as in operations or trauma, and includes red blood cells, plasma, fluid and electrolytes. It is assumed in this discussion that such replacement of acute losses has been made. Occasionally, however, intravenous feeding is necessary for the maintenance or restoration of nutrition. For this purpose plasma or a solution of amino acids is used for nitrogen, and glucose for fuel. Nitrogen and calorie balance can be maintained by these means. However, except for replacement of acute losses, plasma is relatively ineffective. In existing states of protein deficiency and in many cases of burns and other diseases with large protein losses, the requirements are so great that it is physically impossible to satisfy them with plasma. Solutions of amino acids meet this objection and provide a fairly satisfactory means of restoring and maintaining nutrition over relatively long periods. There are numerous drawbacks to intravenous feeding, however. One is the amount of fluid necessary, which may overtax a weak heart, cause circulatory failure, induce or exaggerate edema and even provoke pulmonary edema and secondary pneumonia. Thrombosis of the veins used for injection occurs and may

interfere with prolonged feeding. The psychological influence of eating is lacking. Therefore intravenous feeding, particularly by itself, should be used only after careful consideration of the need and suitability, and for no longer than necessary.

Nothing has been said of vitamins and minerals, which are ordinarily less important to these patients than calories and protein. They will be discussed elsewhere. Except perhaps in burned patients they present little difficulty in previously healthy individuals. Adequate amounts for maintenance should be assured, and if these amounts are not available in the food they should be provided as supplements. In particular, provision should be made for adequate amounts of those vitamins directly concerned with cellular oxidations—thiamin, riboflavin and niacin—when patients are maintained on large intakes of pure carbohydrates, such as glucose, that carry with them no complementary vitamins. When given parenterally somewhat larger doses of these vitamins should be given than normally required because of greater excretion. In previously ill patients, or those seen for the first time with nutritional-deficiency disease, an appraisal should be made of their status in respect to vitamins and minerals and adequate restorative and maintenance treatment should be instituted.

Before leaving the subject of protein nutrition I should like to speak briefly of another condition that has a close similarity to injury and disease so far as liability to protein deficiency is concerned. I refer to pregnancy. The basis for the similarity is as follows. During pregnancy there is normally a positive nitrogen balance occasioned by the need of protein for the products of conception, and probably some for storage against the demands of lactation. If this requirement is not met by the food, the needed amount is taken from the mother's tissues. Thus there occurs a condition similar to the negative nitrogen balance of disease and injury, and if it is anything but minimal and if it continues for anything but a few days there will occur, just as in fractures, burns or typhoid fever, actual protein-deficiency disease. Also, as in fractures and burns, secondary factors may complicate and exaggerate the deficiency in pregnancy. Vagaries of appetite, nausea and vomiting, misinformed restriction of diet and such factors may all have such an effect.

Following delivery there is a negative nitrogen balance. In part this is due to involution, the excess nitrogen coming from the genital organs and tissues. But there may be still another loss, that of lactation. It has been estimated that during lactation 2 gm. of nitrogen is needed every day for every gram of nitrogen in the milk if nitrogen equilibrium is to be maintained.⁸ Loss of blood during delivery constitutes an additional nitrogen loss. Unless sufficient protein is taken in to replace these losses, the protein must come from the maternal tissues. In those

women who have failed to establish an adequate reserve during pregnancy, or who have even suffered from an actual protein deficiency, this additional protein loss may be a serious drain.

Recent studies indicate a close relation between nutrition, particularly protein nutrition, and the toxemias of pregnancy. For example, Tompkins⁹ found four times as many toxemias of pregnancy in a group of women with dietaries limited in protein as in those on a diet containing 110 gm of protein daily, five times as many with edema, and eight times as many with pre-eclampsia. In 1400 pregnant women Holmes¹⁰ found twice as many with toxemias of pregnancy in those with protein intakes of 60 to 70 gm as among those with intakes of 110 to 120 gm. Edema is much oftener due to protein deficiency and hypoproteinemia than to renal or cardiac disease, and some cases of the anemia of pregnancy may have the same cause. Thus, the greater need for protein during pregnancy and the harmful effects of an actual protein deficiency require that protein be furnished in larger amounts at this time. Intakes of at least 1.5 gm per kilogram of body weight should be provided, and somewhat larger amounts are probably desirable. During lactation the intake should equal 2 gm per kilogram.

Two other aspects of protein nutrition of clinical importance in both primary and conditioned deficiency disease received attention during the war. One is the relation of protein to the formation of immune bodies. These substances, which are of vital importance in resistance to infectious disease, are contained in the gamma-globulin fraction of the serum proteins and are elaborated by the globulin-producing cells of the liver and reticuloendothelial tissue. In their formation protein is required, and moreover protein containing the essential amino acids. When the amount of such protein in the diet is inadequate, it can be derived for a time from the body tissues. But, when actual protein deficiency occurs and atrophy of the tissues ensues, production of the immune bodies becomes inadequate. Even the production and activity of the phagocytes is impaired, and this second defense against infection is weakened.¹¹

The other aspect of protein nutrition is the action of the specific amino acids. Since some ten of the amino acids cannot be synthesized by the body and must be obtained in the food or some other exogenous source, it is obvious that deficiencies of these nutrients must occur. As yet, however, there is no known recognizable clinical expression of such deficiencies. We do know, however, that unless these amino acids are present in adequate amounts it is impossible to maintain nitrogen equilibrium, and there is a loss of nitrogen from the body that probably represents the breakdown of some body protein to supply the amino acid for a more essential purpose. Thus there occurs again a loss of protein from the tissues, which, if great enough and long enough

continued, must result in protein deficiency. Therefore it is necessary, in applying protein to prevent or relieve protein deficiencies, to provide protein containing adequate amounts of the essential amino acids.

It is also known that certain amino acids, notably methionine, are utilized in certain processes in the liver concerned with detoxification and that an adequate supply of protein containing such amino acids probably protects the liver against injury in certain endogenous and exogenous intoxications, such as anesthesia,¹² as well as against the effect of certain diseases, such as infectious hepatitis. This protective action fails or is inadequate in cases of protein deficiency.

* * *

Turning now to the vitamins, deficiencies of vitamin A are often neglected in medical practice because of the rarity of xerophthalmia, outspoken night blindness or a severe dermatosis. Perhaps the erroneous concept of vitamin A as the anti-infective vitamin has given it a bad name among doctors. Vitamin A is not per se anti-infective. However, vitamin A deficiency is fairly frequent. Although in a recent review it is stated that it is probably infrequent in this country,¹³ a report from Holland in the following issue of the same journal refers to it as the only vitamin deficiency that was observed in a great number of children.¹⁴ It is the only vitamin deficiency, aside from rickets, commonly seen in Germany and Austria at the present time and has been rather prominent in France, Spain and other European countries. Although the signs and symptoms of the deficiency are not specific, they are suggestive and can be supported by determination of vitamin A concentration in the blood. Distinctly low values for the latter, in the absence of temporary causes, can be considered indicative of vitamin A deficiency from a practical clinical point of view.

Vitamin A is particularly important in pregnancy. The child is dependent on the mother for its supply, and the drop in blood vitamin A seen in the latter months of pregnancy¹⁵ may represent in part the transfer from mother to child. If the mother's supply is low, she may deplete her own store and yet fail to furnish the infant with a sufficient store. When breast fed, the child is dependent on the mother's milk for an increase in its store of vitamin A, which is normally less than that of adults, gradually increasing as the child grows. An inadequate endowment may fail to be improved or even maintained if the child receives an inadequate postpartum supply from its mother, a serious deficiency because vitamin A is important in the growth of children. Fortunately, the widespread use of fish-oil supplements in this country, mainly to prevent rickets, tends to prevent greater deficiency of vitamin A among our children, an important reason for

the use of fish oil concentrates rather than preparations of vitamin D alone at this period of life

Vitamin A deficiency is to be expected in diseases leading to faulty digestion, particularly of fats. It is found also in jaundiced states, because lack of bile hinders absorption, and in various forms of parenchymatous disease of the liver, in which the deficiency may be due to a failure to convert carotene to vitamin A or to store the latter. Recently vitamin A has become of interest in clinical medicine in another way. Vitamin A-tolerance tests, — similar to the glucose-tolerance test, — especially when combined with similar determinations of blood carotene, are useful in the diagnosis of sprue, celiac disease and diseases of the liver of various kinds. The blood levels of carotene and vitamin A are particularly useful in the differential diagnosis of sprue and pernicious anemia, the carotene being low in sprue and normal in pernicious anemia, with vitamin A usually low in sprue and normal in pernicious anemia. Ruffin and Wise¹⁶ have recommended the vitamin A-tolerance test to distinguish between various kinds of hepatitis and obstructive jaundice, tolerance being low in the former and normal in the latter. A high concentration of plasma carotene with a low concentration of vitamin A suggests a failure of liver function. Of even greater interest are preliminary observations of Darby and his associates¹⁷ at Vanderbilt, which suggest that vitamin A tolerance may be a more sensitive indication of recovery of liver functions in infectious hepatitis than such tests as cephalin flocculation.

A deficiency of ascorbic acid is one of the more frequent vitamin deficiencies seen in medical practice, although actual scurvy is uncommon. However, to wait for the appearance of scurvy before considering the possibility and significance of this deficiency is unwise. The pathologic changes of scurvy are progressive, their extent and severity depending on the degree and duration of the deficiency. Before the classic changes of scurvy are observed, less severe but nevertheless harmful lesions must have developed. It is true that scurvy, or even minor deficiency signs, may not appear in subjects experimentally kept on virtually zero intakes for months. This situation, however, is different from that of the patient who for many months or for years has failed to consume adequate amounts and who may have had an inadequate absorption or utilization or a destruction of the vitamin. Because of the frequency of conditioning or predisposing factors in medical practice, doctors should not be misled by misinterpreting data from studies on normal subjects.

Among the most recent findings in regard to vitamin C metabolism, a result of research during the war, are observations such as those of Andrae and Browne,¹⁸ who found a high ascorbic acid retention in patients with thermal burns and fractures. This they believed could not be attributed to pre-existing

deficiency, faulty absorption or impaired excretion, retention in the tissues or edema fluid, or excretion in the form of dehydroascorbic acid. Although the exact significance of these observations is not clear, the large doses of the vitamin retained during the first week of such illnesses suggest the desirability of treatment with large doses of vitamin C in these cases.

Among the vitamin B complex factors, the frequency of thiamin deficiency has, in my opinion, been greatly overestimated and the use of thiamin in practice has been grossly excessive. To begin with, the human requirements for thiamin have been shown to be less than was previously believed. The "recommended allowances" of the National Research Council's Food and Nutrition Board have recently been reduced, and there is good evidence that amounts even considerably less are not accompanied by any recognizable alteration in either nutritional status or physical and psychomotor performance. A source of confusion and error concerning the frequency of thiamin deficiency is mistaken diagnosis in patients said to have beriberi, especially of the wet type, in whom the distal tendon reflexes and the vibratory and other sensory functions are perfectly preserved, and in whom there are no localized muscle weakness and no muscle atrophy. This error has been increased by the erroneous belief that requirements for thiamin are increased in certain environments, such as that of the tropics, and in part by increased excretion in the sweat, neither of which is true. It is interesting that with all the dietary deficiencies that have accompanied the war and involved large populations, thiamin deficiency, except in certain regions in the Pacific and the Far East, has been conspicuous by its rarity. The explanation is found in the long extraction of bread grains that goes with food shortages and the frequent use of various legumes to eke out the supply of flour. The more frequent occurrences in the Pacific seem to be due to the persistence of the custom of using polished rice even when the supply of rice is inadequate. In the Chinese troops I examined, the absence of beriberi was always associated with the use of unhusked rice.

Nevertheless, deficiencies of thiamin do occur, and it must be remembered that slight dietary deficits long continued will eventually deplete the reserves, leaving the person dependent on current intake, which may be sharply reduced by various conditioning factors. Keys and his associates¹⁹ have shown that, although human subjects can be maintained in good condition for weeks on amounts in the neighborhood of 0.22 mg per 1000 calories, a sudden drastic reduction below that level is quickly followed by serious manifestations of deficiency.

One of the newer clinical observations during the war was the finding of a rather large number of cases of severe optic neuritis and, apparently, of neuritis of the eighth nerve caused by thiamin deficiency.

These lesions are, however, apparently encountered only in severe and long-continued deficiency. In ordinary practice they are seen rarely, usually in alcoholic patients.

Although the signs of early or mild thiamin deficiency are not particularly reliable, a near-zero urinary excretion or an extremely poor response to a test dose of the vitamin can for ordinary clinical purposes be considered as indicative of at least a depleted and vulnerable state of thiamin nutrition. In the more acute and severe deficiencies that may suddenly supervene in chronic mild deficiencies, the pyruvic acid concentration in the blood may add helpful evidence if complicating factors of exercise or other disease are eliminated. Diagnosis of a deficiency of thiamin should not ordinarily be made if there is a good urinary excretion of the vitamin.

An important development in respect to riboflavin has been the accumulating evidence of the nonspecificity of some of the manifestations attributed to a deficiency of this vitamin. The latest has been the demonstration by Darby²⁰ that perleche and the glossitis attributed to riboflavin deficiency may respond dramatically, at least in some cases, to the administration of iron, the state of iron deficiency being established by demonstrating a large absorption of radioactive iron (Fig. 1).

Undoubtedly the most important recent development in relation to niacin (nicotinic acid) and pellagra has been the finding of Elvehjem and his associates of the relation of niacin metabolism to the amino acid tryptophane. In their original report these authors²¹ showed that the niacin requirements of rats are apparently greatly increased by the feeding of large amounts of corn. Subsequent studies have shown that the effect is due to the low tryptophane content of the diet, and that the addition of tryptophane increases the bacterial synthesis of niacin in the intestine and enables the animal to grow despite a low dietary intake of niacin.²² Changes in the carbohydrate of the diet have a somewhat similar effect, dextrin favoring the synthesis of niacin, and sucrose lessening it. Although these studies were confined to rats and their significance for man is not fully established, they are cited because they indicate the possibly important role of intestinal bacterial synthesis of vitamins in human nutrition.

The newest vitamin shown definitely to be related to disease in man is a member of the vitamin B complex, the so-called "*L. casei* factor" or folic acid. Previous studies with animals had shown it to be related to diarrhea and anemia in monkeys, under the designation vitamin M,²³ and later to anemia, leukopenia and agranulocytopenia in rats.²⁴ The material was synthesized in 1945.²⁵ Later in the same year, Spies and his associates²⁶ reported that it caused a reticulocytosis, with increased red cells and hemoglobin, in certain human cases of macrocytic anemia that were not well defined by the au-

thors. At about the same time Darby, Jones and Johnson²⁷ reported that in patients with sprue there was a prompt relief of glossitis and stomatitis, cessation of diarrhea, a sharp reticulocytosis followed by an increase of red cells and hemoglobin, great gain in weight and strength, a return to normal of the glucose and vitamin A tolerance and a lessening of fat in the stools following the injection of 15 mg daily. Examination of the bone marrow showed a striking return to normal, with greatly increased

FIGURE 1 Photograph of a Patient with Glossitis and Perleche (Angular Stomatitis)

This woman of forty-five, who had a hemoglobin level of 6.5 gm, was relieved by adequate doses of iron following demonstration of iron deficiency by measured absorption of radioactive iron.

maturation of the red cells. These findings have been amply confirmed. The material has been shown to be effective by mouth, and smaller, though definite, responses have been obtained with much smaller doses. In addition, it has been shown to be effective in anemias of the Addisonian type. Recently Darby and Jones²⁸ have observed a patient with pernicious anemia in relapse who responded with a reticulocytosis of some 25 per cent six days after receiving 3 mg of the vitamin daily by mouth (Fig. 2). This is the more remarkable because the degree of anemia in this patient was not such as to suggest a response of that magnitude from the use of the usual liver extract.

So far the exact relation of this vitamin to the antipernicious principle of liver, to the extrinsic factor of Castle and to other aspects of pernicious anemia is not clear. It is apparent, however, that

we have in this vitamin a powerful agent for the relief and prevention of serious macrocytic anemias, sprue and possibly some disorders of the leukocytes

* * *

Anemia related to folic acid deficiency is not the only anemia caused by nutritional deficiencies. A frequent nutritional anemia is iron-deficiency anemia. This is, in fact, one of the commonest nutritional diseases seen by doctors in this country,

may fail to meet demands. In adults, loss of blood from any one of a great variety of causes — chronic bleeding, hemorrhoids, metrorrhagia, peptic ulcer, frequent pregnancies (complicated by a contribution to the fetus) and surgical operations — may reduce the reserve to a point that makes it impossible to restore normal levels of hemoglobin.

From a dietary and nutritional point of view it is important to note that an anemia of this type will not respond to dietary iron alone. Pharmaceutical

FIGURE 2 Response to Orally Administered Folic Acid
This chart shows the reticulocytosis and response of red cells and hemoglobin to a daily dose of 5 mg of synthetic L. casei factor (folic acid) by mouth in a woman of sixty-three

despite the fact that it is found principally in children and women

Iron-deficiency anemia is almost always a conditioned deficiency in adults, and in them is rarely due to a dietary deficiency of iron alone. The body conserves iron so carefully that almost none is lost except by hemorrhage and, in females, by transfer to the fetus. Children require iron for growth in addition to the endowment they receive from their mothers at birth. From this it is apparent that iron-deficiency anemia occurs under the following circumstances: failure of a normal endowment, intakes inadequate to meet the demands of growth, and hemorrhage. Actually the first two of these mechanisms are often combined. The mother furnishes from her own store, and at its expense, iron for the hemoglobin of the fetus. But with inadequate stores of her own she may fail to endow the infant with sufficient reserve. Growth requires additional amounts, and with an inadequate dietary intake

preparations of iron must be given in adequate doses. These are the reasons why iron-deficiency anemia is so particularly a responsibility of the doctor. Its development is almost entirely due to conditions with which he is directly concerned, its cure requires his services. All this is known to most of us, but the surprising thing is the number of people at the present time with this disease, sufficient to interfere with their health and efficiency, in whom it is not recognized and not treated. Patients with a history of loss of blood are operated on, they lose more blood, they receive one or more transfusions and are finally discharged convalescent with the hemoglobin returning to normal. But it does not reach normal, and a surprising amount of ill-health continues. The proof of the cause of the ill-health is the demonstration of an uptake of iron characteristic of iron deficiency, a response of the blood to adequate doses of iron and a relief of symptoms. Clinically this is shown by a significant reticulocytosis.

This concludes my discussion of some of the phases of nutrition that concern medical practice. If I have dwelt overlong on protein nutrition, it is because I believe that it is the major problem of nutrition in clinical medicine today. On the successful prevention and treatment of this nutritional deficiency disease depend a tremendous improvement in medical care, a great decrease in mortality and morbidity from injury and trauma and from disease and illness of many kinds and great advances in the management of pregnancy, and in child health and development. Other nutrients and nutritional deficiencies are important, and their control will contribute to the improvement in health. By careful individual attention to nutritional requirements and to the prevention or cure of nutritional deficiencies, their ill effects, both primary and on the course of other injury and disease, may be prevented. It is not, however, a thing that can be accomplished without effort. Only if the physician devotes as much attention, relatively, to this as he does to other phases of the care of the sick and injured can he hope to gain for himself and his patients the benefits that our modern knowledge of nutrition has to offer.

THE USE OF THE SOUTH AFRICAN FROG (*XENOPUS LAEVIS*) IN THE DIAGNOSIS OF PREGNANCY*

S L ROBBINS, M D,† F PARKER, JR, M D,‡ AND W C DOYLE, A B §

BOSTON

THE use of the South African clawed frog (*Xenopus laevis*) in a test for pregnancy was first reported some years ago,^{1, 2} only five years after Aschheim and Zondek's original description of the mouse test in 1929.

Like its predecessors, the test is based on the stimulation of the ovaries by the gonadotropic hormones excreted in the urine of pregnant women or of persons harboring neoplastic chorionic tissue

eight hours and usually within twenty-four hours. The clinical importance of this relative speed is obvious in diagnostic problems, such as in threatened rupture of tubal pregnancy and in certain other surgical conditions. Since the frog reacts to a positive test by the extrusion of hundreds of eggs, the simplicity of reading the test is apparent (Figs 1 and 2), obviating the necessity, as in the rabbit, rat or mouse tests, of surgery or sacrifice of the

FIGURE 1 Negative Frog Test

The adult South African clawed frog is peculiarly suited for this procedure because its ovaries always contain eggs, which the frog never extrudes unless it is contacted by the male or unless the ovaries are artificially stimulated by gonadotropic hormones. The frog test has many significant practical and economic advantages over the Aschheim-Zondek and Friedman tests. Whereas the rabbit, rat and mouse tests require two to five days for their performance, the frog test can be read often within

animals to visualize the ovarian changes. In addition, the histologic technics employed in other tests are completely unnecessary in this procedure. The frogs can be used over and over again with thirty days' rest after a positive test and with five days' rest after a negative test. Since these animals cost \$6 apiece and have an active reproductive life of ten to twelve years, the cost of performing each test is rendered appreciably lower than that of other methods in which the use of experimental animals is limited to a single observation or at best to three or four observations. All these factors, together with the ease in maintaining and feeding the frogs, make them wholly satisfactory diagnostic animals for pregnancy tests.

§Laboratory assistant, Mallory Institute of Pathology.

The accuracy of the clawed-frog test, in comparison with that of the older, more widely accepted technics, is perhaps the most important factor. During the past year, over 100 urine specimens have been tested by this method at the Mallory Institute of Pathology. In every case the urine used was one of the routine specimens received daily at the laboratory. It is the purpose of this paper, in addition to emphasizing the many advantages of the clawed-frog method, to report on its reliability in the routine diagnosis of pregnancy.

TECHNIC

As was previously mentioned, the technic for the performance of the test is extremely simple. Eighty cubic centimeters of the first morning urine is required

until at least twenty-four hours has elapsed. It is worth mentioning that cases with suspected low hormone titers, such as may be encountered in very early pregnancy, incomplete abortion or a blighted ovum, can frequently be detected by the concentration of larger volumes of urine (160 cc.), the same procedure as outlined above being used and the final sediment being dissolved in the same volume of saline solution.

RESULTS

For the sake of comparison, the 100 cases in this series have been divided into four groups — those of possible normal pregnancy, those of suspected ectopic pregnancy, those in which the patient was in the process of miscarrying and the problem of

FIGURE 2 Positive Frog Test

Note the numerous eggs on the screen and the floor of the tank

for concentration.³ To this amount is added double the volume of acetone, and the precipitate is spun down in a centrifuge. The supernatant is discarded, and the sediment is washed once or twice with ether by resuspension and centrifugation. After being dried, the material is dissolved in 2 cc of normal physiologic saline solution, the reaction is adjusted to pH 5.5, and 1 cc. of this concentrate is injected into the dorsal lymph sac of each of two frogs. This method concentrates the hormones present in 40 cc. of urine into a volume of 1 cc. In most cases, a positive test, denoted by the extrusion of eggs, can be read within eight to twelve hours. A negative result, however, should not be assumed

the viability of the gestation hinged on the hormone level in the urine and those of obvious intra-abdominal tumor in which the possibility of concomitant pregnancy was entertained. In every case parallel control injections of urine were made into immature rats, following the procedure outlined by Aschheim and Zondek.

In the few cases in which the frog and the rat methods failed to agree, the clinical record of the patient was consulted. Where necessary, through the co-operation of the clinical services, repeated physical examinations and hormone analyses were made until no further doubt about the final diagnosis existed.

The results of the frog test are analyzed in Table 1 from the standpoint of correct or incorrect diagnosis. As the table indicates, in 4 cases the frog test gave false-negative results. In the 2 cases of miscarriage in which the reaction was negative, the clinical courses of the patients were practically identical and in both cases the urine sample had been obtained within hours of the actual passage of the fetus, as the following case indicates:

D McD, a 35-year-old woman, entered the hospital on May 11, 1945, because of the onset of irregular vaginal bleeding, with the passage of clots but no tissue or fetus. The last menstrual period had occurred on January 5. In March there was an episode of slight vaginal staining, which lasted for 2 days. In an effort to determine whether the fetus was still viable, a urine sample was taken on the day of admission. Several hours later the patient passed the fetus. When the urine was tested, the Aschheim-Zondek test was positive, and the frog reaction was negative.

In the 2 cases of ectopic pregnancy in which the frog test gave a false-negative result, the duration of the pregnancies at the time the urine specimens

to assume that the duration of gestation must have been not more than twenty days.

DISCUSSION

As can be seen from the preceding results, no false-positive diagnoses were encountered throughout the series. This finding has been corroborated by many previous investigations.^{4,5} In 4 cases, the frog method gave a false-negative result. The clinical follow-up of these patients showed that in each case the hormone titer of the urine had undoubtedly been low. In the 2 cases of ectopic pregnancy, it is likely that the viability of the products of conception had been impaired, at least to some degree, before the urine sample was obtained, because an equally early ectopic pregnancy in another patient gave a clear-cut positive result with the frog test. In the other 2 cases in which the results with the frogs were incorrect, the patients were in all probability in the process of miscarrying at the time the urine was obtained, and with the death of

were obtained was less than six weeks. The clinical history of the more interesting case 13 as follows:

L C, a 32-year-old housewife, entered the hospital on June 8, 1945, because of the onset of lower abdominal pain of 2 days' duration, accompanied by vaginal bleeding. The last menstrual period, which had occurred at the normal time on May 5, had been more profuse than usual and had been followed by intermittent episodes of spotting. The day prior to admission the patient had passed some clots. She believed that she was pregnant, having subjective symptoms reminiscent of her previous pregnancy. A tentative diagnosis of an incomplete miscarriage was made, and a urine sample was obtained on the day of admission. The Aschheim-Zondek test was positive, and the frog reaction was negative.

Because of the persistence of the vaginal bleeding, a curettage was performed on June 10. The report was as follows: "Decidua-like cells, no definite chorionic villi." The lower abdominal pain persisted, and on July 6 an exploratory laparotomy revealed a left-sided tubal pregnancy. Three days later hormone tests were again performed, and both the rat and frog reactions were negative.

In contrast to this case, it is interesting to note that in another ectopic pregnancy not unlike it, in which the frog test was correct, the period of conception was only five weeks.

The shortest duration of pregnancy detected by the frog test occurred in the normal-pregnancy group and was positive five days after the first missed period. Since the patient followed a relatively exact twenty-eight-day cycle, it seems fair

the chorionic epithelium the hormone levels had fallen to critically low levels.

During the later stages of this series, with increasing experience, it became apparent that these inaccuracies could be avoided, in large part or entirely, by one of several modifications of the original technic, and in the last 78 cases of the series no discrepancies were encountered. Thus, on one occasion, when a pair of frogs received equal volumes of the same urine, one animal responded with the extrusion of eggs and the other frog failed to react, even after twenty-four hours had elapsed. After the passage of another twenty-four hours the latter frog became positive, demonstrating either an extremely low hormone titer in the urine, to which one animal was more sensitive than the other, or a sluggish physiologic response on the part of the late-reacting frog. Therefore, the rare false-negative result can often be avoided by observing all test animals for forty-eight hours.

In an effort to minimize further these false-negative reactions in cases of suspected low titer, we have recently resorted to the use of a concentrate from a larger volume of urine (80 cc), and have as yet encountered no ill effects on the frogs. In the case of the twenty-day period of pregnancy, parallel

jections of a 40-cc and an 80-cc concentrate were made into two pairs of frogs. The animals receiving the larger volume reacted much more vigorously, giving strong positive reactions, whereas the other pair gave extremely weak positive reactions.

It is to be hoped that, with these larger amounts of urine, levels of hormone can be detected that will make the frog test compare favorably in sensitivity with the rat test. It must be acknowledged, however, that when the original technic is followed the frog, although never giving false-positive reactions, appears to be somewhat less sensitive than the immature rat. On the other hand, since adoption of the modifications mentioned above, false-negative reactions in urines of extremely low titer have been avoided.

SUMMARY

The extrusion of eggs by the South African clawed frog on stimulation by mammalian gonadotropic hormones, such as are excreted in the urine of women during pregnancy, offers a desirable test for pregnancy. Among its advantages are speed, since ordinarily only eight to twelve hours are required for a positive reaction, ease in the performance and reading of the test, economy, since

the animals can be reused over a period of many years, and simplicity in feeding and maintenance of the animals, since they require no elaborate or separate animal rooms.

In a carefully controlled series of 100 consecutive routine urine analyses, the test gave no false-positive reactions, but in 4 cases of low-titer urines it failed to give a positive reaction. It is believed that with minor modifications in the original technic these false-negative reactions can be avoided and that this test can be made to compare favorably with the older, more widely accepted rabbit, rat and mouse tests. The rapid diagnosis that it affords is desirable in general, and in cases presenting difficult diagnostic problems this factor may be of great value in indicating the correct therapeutic procedure to be adopted.

THE ORAL LESIONS OF MONOCYTIC LEUKEMIA*

Report of a Case

FRANCIS P. MCCARTHY, M.D.,† AND PAUL H. KARCHER, D.M.D.‡

QUINCY, MASSACHUSETTS

IN REPORTING this case of subacute monocytic leukemia, the oral lesions are particularly stressed, since they dominated the clinical picture almost from the onset of the blood dyscrasia.

Oral lesions represent a frequent and early finding in the various types of leukemia, especially in the acute forms. In monocytic leukemia, which represents 5 per cent of all the cases of leukemia, gingival and other oral changes occur in an extremely high percentage of cases except in edentulous mouths. Indeed, much of the suffering experienced by the patient in monocytic leukemia is related to the pain and discomfort from the necrotic and ulcerative lesions of the gingival and buccal mucosa, the highest percentage of lesions being found in the acute cases. Love¹ reported 82 of 152 cases of various types of leukemia with oral lesions. The most frequent sign was bleeding from the gums, with swelling, necrosis and ulceration of the gin-

givae. Forkner² states that in acute monocytic leukemia acute swelling of the gingivae with a tendency for the teeth to become submerged in the gums is encountered in the great majority of cases. He believes that the infiltrative lesions of the gums are always pathognomonic of acute monocytic leukemia. Osgood³ reviewed a series of cases of monocytic leukemia and reported that gingival swelling was noted in 80 per cent of 88 cases in which the gums were mentioned. Klumpp and Evans⁴ report that of 8 cases of monocytic leukemia 5 were discovered following extraction of the teeth, and conclude that oral lesions are frequent in acute leukemia and are prone to occur early in the disease. Moloney⁵ in reporting 9 cases of leukemia found that 7 patients first visited the doctor or dentist because of bleeding from the gums, "trench mouth" or pain in the jaw. He concludes that palliative measures and the avoidance of injudicious oral surgery make the patient much more comfortable.

There are many other causes of gingival hyperplasia with edema, necrosis and a tendency to bleed from the gums, either spontaneously or from slight

THE ORAL LESIONS OF MONOCYTIC LEUKEMIA*

Report of a Case

FRANCIS P. MCCARTHY, M.D.,† AND PAUL H. KARCHER, D.M.D.‡

QUINCY, MASSACHUSETTS

IN REPORTING this case of subacute monocytic leukemia, the oral lesions are particularly stressed, since they dominated the clinical picture almost from the onset of the blood dyscrasia.

Oral lesions represent a frequent and early finding in the various types of leukemia, especially in the acute forms. In monocytic leukemia, which represents 5 per cent of all the cases of leukemia, gingival and other oral changes occur in an extremely high percentage of cases except in edentulous mouths. Indeed, much of the suffering experienced by the patient in monocytic leukemia is related to the pain and discomfort from the necrotic and ulcerative lesions of the gingival and buccal mucosa, the highest percentage of lesions being found in the acute cases. Love¹ reported 82 of 152 cases of various types of leukemia with oral lesions. The most frequent sign was bleeding from the gums, with swelling, necrosis and ulceration of the gin-

givae. Forlner² states that in acute monocytic leukemia acute swelling of the gingivae with a tendency for the teeth to become submerged in the gums is encountered in the great majority of cases. He believes that the infiltrative lesions of the gums are always pathognomonic of acute monocytic leukemia. Osgood³ reviewed a series of cases of monocytic leukemia and reported that gingival swelling was noted in 80 per cent of 88 cases in which the gums were mentioned. trauma In the treatment of epilepsy with dilantin extreme cases of gingival hyperplasia, in many of which the teeth are completely obscured, occur in about 50 per cent of patients.⁶ The hyperplasia develops principally on the labial aspect of the gingivae in these cases. In all cases of Vincent's infection of the gingivae, with its associated redness and necrosis and fetid breath, it is desirable to make an examination of the blood to rule out a severe blood dyscrasia. Aplastic anemia, agranulocytosis, infectious mononucleosis and reaction to many drugs may cause acute gingival necrotic lesions similar to the lesions found in leukemia. The blood picture, together with other physical findings, should enable

spleen were not palpable, and the chest was clear of rales. The white-cell count was 17,530, with 33 per cent mature neutrophils, 3 per cent metamyelocytes, 1 per cent myelocytes, 2 per cent myeloblasts, 1 per cent eosinophils, 28 per cent lymphocytes and 32 per cent monocytes, 2 histiocytes were seen. Oral examination revealed a marked hypertrophic condition of the gingival papillae. They were extremely soft and spongy and bled easily when touched. A sternal puncture yielded an almost pure culture of large mononuclear cells, with an extreme reduction of the normal cellular elements of the marrow. A diagnosis of subacute monocytic leukemia was made. During the patient's stay the course of the illness was progressively downhill, although there were temporary responses to transfusions and injections of a bone-marrow stimulant. The patient ran a spiking temperature up to 102°F during the hospital course, and the gums failed to respond to radiation therapy.

On entrance to the Quincy City Hospital 3 months after the onset of the disease, the oral condition was further advanced (Fig. 1). The patient complained particularly of the

FIGURE 1 Photograph of the Teeth and Gums

Note the marked hyperplasia of the gingiva, which almost completely obscures the lower cuspid teeth

one to differentiate the etiologic factors in these cases

L. T., a 27-year-old woman, was admitted to the Quincy City Hospital on February 3, 1945. The family history was negative. The patient's parents, both of two brothers and a sister were living and well. She had had no previous serious illness and had the usual children's diseases at an early age.

Three months previously the patient had first complained of a severe headache, which was located in the orbital, frontal and occipital regions. There was an associated inflammation of the eyelids, with a slight exudate. There was chronic nausea with occasional attacks of vomiting almost from the beginning of the illness, and a weight loss of 50 pounds in 3 months. The patient was admitted to the Clinic Consultation Service of the Pratt Diagnostic Hospital on January 3, 1945, and was discharged on January 18. On entrance there she appeared quite sick, and in addition to bleeding and swollen gums showed swollen eyelids, with a mild conjunctivitis. Physical examination revealed marked emaciation, with extreme pallor of the skin. The liver and

pain and discomfort in the mouth. There was dysphagia and increased salivation but no bleeding from the gums. A pronounced fetid odor to the breath similar to the odor found in cases of acute Vincent's infection was present. There was a moderate swelling of the gums, which were bright red and edematous, with elongation of the interdental papillae. A superficial grayish slough was noted at the borders of the papillae, similar to that seen in acute Vincent's gingival infection.

Smears taken shortly after entrance revealed a rich bacterial flora, with Vincent's spirochetes and fusiform bacilli predominating. The teeth appeared to be in good condition, with the exception of the superior left 1st molar, which showed extensive caries. The buccal mucosa showed generalized reddening, but no areas of necrosis or purpuric lesions were noted. The cervical lymph nodes were moderately enlarged, especially in the submental and submaxillary regions, and palpation of these nodes elicited moderate tenderness.

There was progressive involvement of the tissues of the oral cavity until death, which occurred on March 14, in spite of local and constitutional treatment, including multiple

blood transfusions. The hyperplastic gum tissue increased in size along both the labial and lingual surfaces of the alveolus. The entire arch became broad and was made up of swollen, edematous, necrotic, vascular gingival tissue that gradually obscured the teeth. Three or 4 weeks after the initial examination, a secondary growth of hyperplastic tissue developed at the base, following the same pattern as the outer layer and increasing the width of the alveolus to such an extent that the palatal vault was all but eliminated. The floor of the mouth above the myohoid ridges was also partially filled with vascular, necrotic gingival tissue, so that the tongue was raised and there was inability to close the mouth.

The mouth remained extremely dry, partly owing to evaporation, and new superficial necrotic lesions of the mucosa developed, with secondary gangrenous changes. These areas, which were located on the lateral margins of the tongue and the buccal mucosa of the cheeks, were covered by a pale-yellow pseudomembrane, which on peeling left a raw, bleeding surface. There was an ulcerated lesion on the right lateral palatal region near the 1st molar tooth and another involving the left side of the soft palate and extending to the anterior pillar of the fauces. Four days before death, fairly generalized petechial and purpuric macular lesions appeared on the buccal mucosa, concomitant with similar hemorrhagic lesions of the skin over the face. Inspissated blood, mucus, detritus and exudate formed a hard shell on the dorsum of the tongue. This deposit was softened and removed daily. Following the formation of the secondary hyperplastic gum tissue, the teeth tended to migrate and to assume fantastic positions in the arch, indicating destruction of the alveolar lamina dura.

A biopsy specimen taken from an interdental papilla showed the following histologic picture. The outer labial stratified epithelial surface was thinned out, especially in the prickle-cell layer. There was considerable edema of the underlying tunica propria, with increased capillary vascularity. There was a wide zone of edematous fibroblastic connective tissue moderately infiltrated with monocytes and cells of the lymphoid type, with rare polymorphonuclear leukocytes. The monocytes represented 50 per cent of the infiltrating cells. Deeper in the specimen was less edematous and more pronounced cellular tissue, consisting principally of closely packed monocytic cells with a few lymphocytes. The large vessels were choked with monocytes. The dental surface of the gum tissue showed marked necrosis, with absence of the epithelial surface layer. The infiltration of monocytes was especially pronounced, and there were numerous foci of hemorrhage. This portion of the specimen represented the site from which a rich bacterial flora and Vincent's organisms were demonstrated on smears.

The local treatment to the oral cavity given by one of us (P.H.K.) consisted of irrigations with warm normal saline solution, which tended to keep the exudate softened and helped in removing the pseudomembrane from the necrotic surfaces of the gingival and buccal mucosa. This procedure was frequently used during the daytime and gave considerable relief from the pain and dryness in the mouth. Zinc peroxide dusted into the deep recesses of the necrotic and hyperplastic tissue, especially after eating, and neosarsphenamine in glycerin—0.8 gm to 30 cc of glycerin—swabbed into the necrotic pockets helped to control the secondary invasion of Vincent's organisms. Six-millimeter gauze strips saturated with oil esthesin, an oil-base surface anesthetic, placed in the superior and inferior vestibule of the mouth three times daily after eating controlled much of the pain. Hyperplastic necrotic and gangrenous tabs of tissue were cut away with a scalpel and curved scissors, giving much relief. Vaseline smeared on the lips and commissure kept them soft.

Autopsy. The body was that of a fairly well developed and poorly nourished young woman. The scleras and skin had a moderately icteric tinge. There were purpuric and petechial hemorrhages on the face, especially the alae nasi, and the forearms. There were recent organizing fibrinous adhesions binding the right lung to the chest wall and obliterating the pericardial sac.

In the upper half of the lower lobe of the right lung, there were multiple milary abscesses surrounded by areas of consolidation up to 1 cm in diameter. Both the spleen and the liver were enlarged, and the malpighian bodies in the spleen were barely visible. The kidneys were remarkable in appearance. Their combined weight was 360 gm. Removal of the capsules revealed smooth, canary-yellow cortical surfaces

with an average thickness of 1.2 cm. The line of demarcation between the cortices and pyramids was barely discernible, and there were multiple petechial and large hemorrhagic foci throughout the parenchyma of both kidneys and also in the pelves. There was no evidence of adenopathy in the cervical, axillary and inguinal nodes.

Microscopical examination of the viscera revealed the following: **Kidneys.** The tubular epithelium took the stain extremely faintly, and many of the cells show only nuclear staining. There was a diffuse cellular infiltration of the connective tissue with monocytes and lymphoid cells. The convoluted tubules showed the most pronounced evidence of epithelial degeneration. Hyaline casts were demonstrated in the tubules throughout the specimen. The long, straight veins of the pyramids were congested. Focal areas of hemorrhage occurred in the cortex and pyramids. **Spleen.** The spleen showed a diffuse infiltration with monocytes and cells of the lymphoid type and rare eosinophils. Phagocytic cells containing brownish granular pigment were diffused throughout the pulp. The capillaries were dilated with focal areas of hemorrhage. The malpighian bodies were small and disorganized. **Liver.** The interlobular connective tissue of the liver showed a marked cellular infiltration, principally monocytic. The capillaries and sinusoids revealed similar infiltration. The capsule and subcapsular space showed an extreme monocytic cellular infiltration. The liver cells took the stain extremely faintly, and many contained vacuoles. There was a moderate proliferation of the bile ducts. Focal areas of hemorrhage occurred throughout the organ. **Lymph Nodes.** The architecture of the lymph nodes was obliterated, although the germinal centers of the lymph follicles were discernible. There was a diffuse infiltration of the nodes and capsules with monocytic cells and lymphoid cells (Fig. 2).

FIGURE 2 Photomicrograph of a Section of Lymph Node Showing Diffuse Infiltration with Monocytic and Lymphocytic cells

No polymorphonuclear leukocytes or eosinophils were demonstrated. **Bone Marrow.** The bone marrow of the rib showed a significant reduction in the normal cellular components. There was a marked increase in monocytes, which represented 80 per cent of the total cells. A few myelocytes, lymphocytes and nucleated red cells were demonstrated. **Blood.** A stained smear showed lymphocytes and monocytes, with relatively few polymorphonuclear cells (Fig. 3).

The anatomical diagnoses were as follows: subacute monocytic leukemia, acute hemorrhagic nephritis, fatty degeneration and infiltration of the liver, subacute adhesive pericarditis, splenomegaly, septic bronchopneumonia of the right lung, icterus, purpura hemorrhagica, hyperplastic stomatitis, with necrosis and purpura, ulcerative enterocolitis, monocytic hyperplasia of the bone marrow, and monocytic infiltration of the viscera.

Lesions of the oral mucosa with extensive involvement of the gingivae represent important complications in acute and subacute monocytic leukemia, particularly since much of the suffering is caused by them. It is desirable that the dental consultant

Treatment of these lesions by the dental consultant was helpful in relieving the acute symptoms in this case.

In monocytic leukemia, involvement of the oral cavity occurs more frequently than in any other

FIGURE 3 Photomicrograph of a Blood Smear Showing Lymphocytosis and Monocytosis but Relatively Few Polymorphonuclear Leukocytes

take over the management and treatment of the case as it relates to the mouth, and that he apply the treatment either personally or under direct supervision so that the patient may be relieved of the intense discomfort attending these cases. In all cases of gingival hyperplasia with bleeding and a tendency to necrosis, with secondary Vincent's infection, blood examinations should be made to rule out serious blood dyscrasias.

SUMMARY

A case of subacute monocytic leukemia is described, with special reference to the oral lesions.

type of leukemia and is often an early manifestation.

MEDICAL PROGRESS

FLUORINE AND DENTAL CARIES (Concluded)

VLADO A. GETTING, M.D.*

BOSTON

EFFECT OF FLUORINE ON DENTAL CARIES

THE earliest references in the literature on the relation of fluorine to dental caries were made in 1916 by McKay and Black,^{56, 57} who studied the so-called "Colorado brown stain." During the following decade mottled enamel and dental caries were extensively studied by McKay^{58, 59} and Bunting et al.⁶¹ It was not until 1931, however, according to Dean⁶⁰ that fluorine was discovered as the cause of mottled enamel. Four methods were used in studying the cause, prevalence and control of mottled enamel and the lowered prevalence of dental caries in certain areas. These consisted in refinements in measuring the rates of prevalence of caries in relation to age, sex and race⁶¹, elimination of the circulation factor, or limitation of observations to persons continuously exposed to the specific environment factor under investigation — the common water supply⁶², the development of a chemical method permitting water analyses that were accurate to 0.1 part per million of fluorine⁶³, and the development of quantitative methods for estimating the number of *Lactobacillus acidophilus* in saliva, this being used as an index of the activity of dental caries.⁶⁴

The role of fluorine in dental health is ably described in a monograph entitled *Fluorine and Dental Health*, a publication of the American Association for the Advancement of Science edited by Moulton.⁶⁵ Another important monograph, entitled *Fluorine in Dental Public Health*,⁶⁶ is the report of a symposium at the ninety-fourth monthly conference of the New York Institute of Clinical Oral Pathology, held in New York City in 1944. Finally, by resolve of the General Court, the Massachusetts Department of Public Health⁶⁷ prepared in 1945 a monograph entitled *Special Report Relative to the Decay of Teeth Resulting from a Lack of Fluorine*.

Mottled Enamel

Following the original work of McKay⁶⁸ in discovering the condition now called mottled enamel, surveys were made in other communities in which discolored teeth were prevalent.⁶⁹ The relation of mottled enamel to water supplies from deep wells had been established as long ago as 1918 by the same author,⁶⁹ but it was not until 1932 that the

fluorine content of water supplies was related to this condition.⁷⁰ In 1928, the United States Public Health Service undertook to investigate mottled enamel and deformity of teeth of children at Bauxite, Arkansas. The Aluminum Company of America,⁷¹ which owned a mine near which the town was located, caused samples of water to be examined in its laboratory. This examination disclosed that the water from the deep wells supplying the town contained an unusually high content of fluorine. Soon similar findings revealed that a water supply of a high fluorine content was a common factor among children who had developed mottled enamel. Examination of water supplies in communities in which no mottling was found revealed that fluorine was present in extremely small quantities, less than two parts per million.

It was recommended that Bauxite obtain a water supply that did not contain fluorine,⁷² and this was done. In 1938, ten years after the town had begun taking water from the Saline River, which contained practically no fluorine, Dean⁷⁴ and others⁷⁵ reported that all children who had used the water from the deep wells during infancy and early childhood showed mottled enamel. On the other hand, the same children exhibited a low incidence of dental caries, even though they had been using fluorine-free water for twelve years. In contrast, children living in the nearby town of Benton, who had used Saline River water throughout their lifetime, showed no mottling of enamel but a high prevalence of dental caries. Other evidences of the beneficial effects of fluorine were also found. Children of Bauxite who were born within a few years after the change in water supply and had therefore used the old water for only three or four years showed practically no mottling but had a low incidence of dental caries. The children born after the new water supply was obtained showed the highest caries index. Similarly, mottled enamel has been eliminated at Oakley, Idaho, and Andover, South Dakota, by changing the water supply from one containing amounts of fluorides toxic to calcifying dental enamel to one with a fluoride content not

*Numerous attempts^{73, 74} have been made to remove excess fluorine from water supplies by using tricalcium phosphate, magnesium oxide or magnesium hydroxide. Of these chemicals, magnesium oxide is the least expensive. The commercial light grade is better than the commercial calcined one, but its higher cost is not in proportion to its greater efficiency. It may be stated that whenever possible it is better to obtain a new water supply containing only 1 p.p.m. (part per million) of fluorine than to attempt defluorination.

*Commissioner, Massachusetts Department of Public Health and lecturer in public health practice, Harvard School of Public Health.

exceeding 1 p p m ⁷⁶ The unusually long interval in time, eight to ten years, before the clinical effects resultant from a change in the water supply may be observed clinically, is unique in epidemiologic investigations of water-borne diseases

Communities, seeking new water supplies⁷⁷ in areas where deep wells are required should have detailed chemical analyses performed before making the new supply available to the public The city of Narka, Kansas, developed two new deep wells 262 feet deep, the water from these contained 12 and 13 p p m of fluorine, respectively Epidemiologic investigation of private water supplies from deep wells in the areas surrounding the new wells, however, showed that 8 children who were raised on these private supplies containing 0.8 to 3.0 p p m of fluorine had not developed mottled enamel Hence, the new supply was made available

FLUORINE-CONTAINING WATER SUPPLIES AND DENTAL CARIES

Meanwhile, other studies had been in progress to determine how much benefit fluorine exerted in the prevention of dental caries The South Dakota studies made by Dean and McKay⁷⁶ in 1938 showed sharp differences in the prevalence of dental caries, depending on whether the population was affected with dental fluorosis Dean and McKay's article contains a report on the examination of 236 nine-year-old children with a verified continuity of exposure to the fluorine-containing domestic waters of the cities in which they lived It was noted that there was relative freedom from dental caries in deciduous teeth as well as permanent teeth, whether or not the teeth showed macroscopic evidence of mottled enamel In 1939, Dean et al ⁷⁸ and others⁷⁹ reported a study of four cities in Illinois In Galesburg and Monmouth, where the water contained 1.8 and 1.7 p p m of fluorine, respectively, the children examined showed an average of 2.0 DMF teeth per child In Macomb and Quincy, where the water supplies contained only 0.2 p p m of fluorine, the children showed an average of 4.0 and 6.3 DMF teeth, respectively

Another study was made by Dean and others⁸⁰ to determine the lowest concentration effective in reducing the incidence of dental caries and the magnitude of this inhibition Eight suburban cities around Chicago were selected The water of Elmhurst, Maywood, Aurora and Joliet had 1.8, 1.2, 1.2, and 1.3 p p m of fluorine, respectively Elgin was intermediate, with 0.5 p p m, and Evanston, Oak Park and Waukegan used fluorine-free water The prevalence of dental caries in these eight cities, expressed as an average of the number of DMF teeth per child, was as follows Elmhurst, 2.5, Maywood, 2.6, Aurora, 2.8, Joliet, 3.2, Elgin, 4.4, Evanston, 6.7, Oak Park, 7.2, and Waukegan, 8.1

It will be seen that children living in the communities using water with the higher fluorine con-

tent had markedly less dental caries than did those living in communities using fluorine-free water, and that 0.5 p p m was not sufficient to give appreciable protection The populations in these cities were so nearly similar from other points of view that it is difficult to ascribe these differences in the prevalence of dental caries to any other cause than the differences in the concentration of fluorine in the water supply Moreover, the inhibiting effect was exhibited at such a low concentration that mottled enamel as an esthetic problem was not encountered

In another study,⁸¹ including examinations of children in twenty-one cities in four states, the level at which the inhibiting factors operate was made even clearer (Table 3) It will be noted that there was a marked drop in the beneficial effect when the concentration was under 0.5 p p m of fluorine, and

TABLE 3 Relation of the Prevalence of Dental Caries to the Fluorine Content of Water Supplies

FLUORINE CONCENTRATION OF WATER SUPPLY	NO. OF CITIES	NO. OF CHILDREN EXAMINED	NO. OF PERMANENT TEETH SHOWING DENTAL CARIES PER 100 CHILDREN
p p m			
Less than 0.5	11	3,867	700+
0.5 to 0.9	3	1,140	400+
0.9 to 1.4	4	1,403	300
More than 1.4	3	847	250

that there was no appreciable increase in the inhibiting effect when the concentration was above 1.4 p p m

The mechanism whereby this element contributes to the prevention of dental decay is thought to be primarily one of increased fluorine content of the tooth enamel ⁸² This may result from incorporation of fluorine in the tooth during the period of tooth formation or by acquisition of fluorine from the external surface of the tooth after eruption There is an affinity between the calcium phosphates of the tooth and fluorine This fluorine increment in the enamel makes the tooth less soluble in acids Also, in an environment of fluorine the acid and bacteria in the vicinity of the teeth are reduced Thus, it seems that at least one substance has been found that successfully counteracts the effects of acids produced by the growth of bacteria in the presence of carbohydrates

ADDITION OF FLUORIDES TO PUBLIC WATER SUPPLIES

Since it has been demonstrated that fluorine found naturally in water supplies combats the inroads of dental caries, one of the first practical questions that arise is whether this useful element can be purposely supplied in areas where it is absent from or extremely low in the water supply Any domestic water supply, so far as its fluoride content influences dental health, may be thought of as falling into one of three classes — water supplies naturally

with the optimal concentration of fluorine (about 10 p.p.m.), water supplies with an excess of fluorine, requiring its removal to protect the population against endemic dental fluorosis (mottled enamel) or its replacement by or mixture with other water supplies low in fluoride, and water supplies deficient in fluorine, to which it might be added to bring about an optimal concentration of this element so as to lessen the amount of dental decay.

Several states have made detailed analyses of the fluorine content of public and semipublic water supplies. New Jersey has six communities with public water supplies having a fluorine content between 10 and 24 p.p.m. This survey, conducted by Wisan,⁵² revealed that children in these communities had a lower caries rate than children living in communities serviced with fluorine-free water. Extensive studies have been made of water supplies in Florida,⁵³ Illinois,⁵⁴ Indiana,⁵⁴ Louisiana,⁵⁵ Nebraska,⁵⁶ New Mexico,⁵⁷ North Dakota,⁵⁸ Ohio,⁵⁹ South Dakota,⁶⁰ Texas,⁶¹ Utah,⁶² Virginia,⁶³ and Wisconsin⁶⁴ and in 1945 complete mineral-water

presence of fluorine in excess of 15 p.p.m. shall constitute grounds for rejection of the supply.

Massachusetts⁶⁷ waters contain extremely small concentrations of fluorine. The maximum quantity found in any one sample was 12 p.p.m. in the semipublic supply at Farnumsville in Grafton. Unfortunately, the number of children who continuously used this supply was too small to justify any conclusions relative to the effect of the fluorine on the caries rate. Fluorine concentrations of 10 and 0.7 p.p.m., respectively, were found in deep wells used only as auxiliary water supplies at Lyonsville in Colrain and at Fisherville in Grafton, but the regular water supplies of these communities were low in fluorine. Of 368 samples analyzed, 359 (98 per cent) contained 0.2 p.p.m. or less, and 229 (62 per cent) contained 0.1 p.p.m. or less. The average of all samples was 0.11 p.p.m., an amount that is far below the optimal 10 p.p.m. that is effective in lessening dental caries.

Sodium fluoride may be added in correct amounts to a water supply. Ast⁶⁸ describes a plan to deter-

TABLE 4 Data on Topical Application of Fluoride

PLACE AND AUTHOR	CHILDREN		NO. OF TREATMENTS PER YEAR	STRENGTH OF FLUORIDE SOLUTION	REDUCTION IN CARIES RATE
	NO.	AGES			
Brockton, Mass. (Bibby ⁶⁹)	90	10-13	3	0.1 (NaF)	46
Indiana (Cherney ⁷⁰)	46	4-6	2	0.05 (KF)	50
Minnesota (Knutson and Armstrong ⁷¹)	289	7-15	(in 4 mo.) 7-15 (in 8 wk.)	2.0 (NaF)	40
Coast Guard (Arnold et al. ⁷²)	188	17-22	1	1.0 (NaF— acidulated)	0
Cambridge, Mass. (McKelleget and Bibby ⁷³)	47	6-14	3	1.0 (NaF)	43
Millville, Mass. (Labunsky and Bibby ⁷⁴)	91	6-14	2	1.0 (NaF)	25

analyses were made of all public and semipublic water supplies in Massachusetts.⁶⁷ The literature contains many references to the finding of endemic fluorosis in Argentina, Australia, China, Chosen, Ecuador, England, Greenland, India, Malaya, Mexico, Java, South Africa, Tristan da Cunha and Western Asia (Iraq, Trans-Jordan, Syria, the Bahrein Islands, Arabia and Palestine).⁶⁵

The present standard for fluorine content of public water supplies, as defined by the United States Public Health Service, calls for the rejection of the water supply if it contains more than 10 p.p.m. The recommended methods of analysis of water supplies are those contained in *Standard Methods for the Examination of Water and Sewage* of the American Public Health Association and a committee report, "Methods of Determining Fluorides," that appeared in 1941 in the *Journal of the American Water Works Association*.⁷⁵

A circular letter from the United States Public Health Service to the Advisory Committee on Drinking Water Standards,⁷⁶ on the tentative revision of the 1942 standards, recommends that the

mine the practicability, efficacy and safety of fluorinating a communal water supply deficient in fluorine to control dental caries. Three communities are now conducting such studies—Grand Rapids, Michigan,⁷⁷ Newburgh, New York⁷⁸ and Marshall, Texas.⁷⁹

TOPICAL APPLICATION OF FLUORIDES

Because it was suspected that fluorine could act directly on the teeth through the external surface, one of the first methods of using fluorine was the application of solutions of sodium fluoride directly to the teeth, either in the mixtures used in cleaning the teeth or in simple solutions after such cleaning had been performed by dentists and their assistants.⁶⁶ The results of a few of these studies are shown in Table 4.⁷⁷

It will be seen that when these applications are made in children of the youngest age groups, the caries reduction varies from 25 to 50 per cent and that similar applications in adults produce little effect. Undoubtedly, when the proper concentration of solutions and the optimum number of appli-

cations have been determined, one can expect the caries reduction to be regularly over 50 per cent. The principal drawback of this method of the use of fluorine is that it must be carried out in the dentist's office or under the supervision of a dentist, and that the results will be limited by the fact that there are not sufficient dentists and dental assistants¹⁰⁴ available to give treatments to all of the persons in the areas in which the fluorine content of the water supply is low. Other methods of using fluorine must therefore be found to supplement direct applications in the dentist's office. At the present time, studies are in progress in various states to determine whether fluoride added to mouthwashes or dentifrices exerts a beneficial effect.

Fluorine in Foods

The question has been raised whether sufficient amounts of fluorine can be obtained from food materials to exert a beneficial effect. This matter has been investigated by a number of workers^{105, 106}. It has been found that most foodstuffs contain extremely small quantities of fluorine. As would be expected, the quantities are somewhat increased in high-fluorine areas, particularly if vegetables are irrigated or sprayed with water containing fluorine. The supply of foodstuffs coming from such areas, however, constitutes such a small portion of the total quantities used that the general level of fluorine is not raised to any significant degree. It has been found that fluorine is excreted in the feces, urine and sweat in sufficient quantities so that the amount obtained from food supplies is lost so promptly that no beneficial effects can be expected¹⁰⁷. The only food materials with a high quantity of fluorine are those that contain bone or bone meal, such as small fish the bones of which are consumed or baby foods to which bone meal has been added. It has been observed that certain primitive peoples who depend largely on fish for protein show a low attack rate of dental caries. It may be that this is due to the fluorine in the bones of the fish.

Although this field has not been thoroughly explored, it appears likely that persons living in modern American communities will not receive much benefit from fluorine obtained from food supplies. If it is eventually demonstrated that the beneficial effect of fluorine is due to the local contact when water flows over the teeth and not to the fact that fluoride is assimilated by the blood supply, this may further explain why fluorine in foods is not more effective, since it is not so easily available for a local effect, being intimately bound up with the foods.

* * *

It will be seen from the foregoing discussion that all practitioners of the healing arts have good reason to believe that fluorine exerts a direct beneficial effect in preventing dental caries. It may even

be that the higher prevalence of dental defects in New England, as well as elsewhere, can be ascribed to the absence of this useful chemical. If this proves to be the case, the simple addition of fluoride to water supplies or to other materials widely used by the public may exert a profound effect on this public-health problem. It is important, however, that fluorine be used judiciously, because it not only exerts a beneficial effect but if used in excess may have a deleterious effect on the teeth. Care must therefore be employed against supplying the chemical in amounts large enough to produce dental fluorosis.

There are probably many factors that affect the action of fluorine that are yet to be investigated. For instance, it has been noted that in northern India, where the fluorine content of the water supply is high and the general diet is superior, the natives do not develop fluorosis¹⁰⁸. On the other hand, the condition is frequently seen in southern India, where the diet is much less adequate and the fluorine content of the water is no higher. Susceptibility to fluorosis therefore seems to increase through lack of certain essential nutrients.

CURRENT RESEARCH ON DENTAL CARIES AND FLUORINE

Further studies are necessary to determine the best methods for utilizing this useful chemical. To learn of any research recently begun or in progress in other states that has not yet been described in public-health and dental journals, letters were sent to all the health officers of the states and provinces of the United States and Canada asking for such details as were available. Attention was called to the fact that the Massachusetts Department of Public Health was particularly interested in research regarding the effect of fluorine. The information obtained is summarized in Table 5, and a short description of the projects in a few of the states follows.

Alabama Studies are being conducted in establishing prevalence rates for dental disease. The Department of Geology of the University of Alabama is making a study of the ground-water supply, financed by the State Health Department, to determine the amount of sodium fluoride it contains. State-sponsored clinics will utilize topical applications of sodium fluoride on half of a series of patients, the other half serving as controls. Further work on the use of fluoride in topical applications will be carried on, the state dentist working in collaboration with the Department of Geology of the University of Alabama.

California Drs. Becks and Wainwright, of the California Dental College, have carried out studies on the relation of *B. acidophilus* to dental caries. Becks and his co-workers are also studying the effect of fluorides on dental tissues.

Connecticut Projects have been set up to show the local effects of fluorides on tooth structures. These include the study of the effect of adding fluoride to the water supply of the Southbury Training School, tooth analyses are being made

Illinois Plans are being made for a study of the use of fluoride in the public water supply as a dental decay preventive in Evanston. Previous work has been done by the United States Public Health Service on the relation between dental caries and

and *B. acidophilus* counts recorded. Topical applications of fluoride are being studied at the County Temporary Home for Children. The effects of a mouthwash containing 5 p.p.m. of sodium fluoride are being examined.

Georgia Preliminary studies are being made by Dr. Dean, of the United States Public Health Service, in an area low in caries prevalence to ascertain the basis for the low attack rate and its relation to the concentration of fluorine in the water supply.

the fluorine content of the local water supplies in several cities.

Iowa During the last three years there were conducted oral examinations of 12,000 high-school pupils in areas with water supplies high and low in fluorine. The average DMF rate per 100 children in the high areas was 200 to 300, that in the low areas ranged from 300 to 600.

Kansas Surveys have been conducted of the distribution of fluorine in city water supplies and the DMF rates of children in the eastern third

and the western third of the state. High rates were found in low-fluorine areas.

Maine An investigation of the incidence of caries was conducted for a number of years, and a study of the analysis of drinking water was made.

Maryland A prewar investigation of fluorine in water supplies was begun by the United States Public Health Service but has been delayed until more personnel is added. A statistical study of caries was made.

Massachusetts Study of the effect of fluorine on decay of the teeth has been authorized by the Legislature, with a small appropriation. Some studies on fluorine had already been begun by the Tufts College Dental School and the Massachusetts Department of Public Health. Surveys of the prevalence of dental caries are in progress. The fluorine content of all public water supplies has been determined. These activities are to be extended with the expansion of dental personnel and formation of a division of dental health.

Michigan The Department of Public Health and the United States Public Health Service are conducting a pilot program in the utilization of 1 p.p.m. of sodium fluoride in the public water supply of Grand Rapids as a preventive of dental caries. Other projects are being carried on in the field of fluoride therapy and diet at the University of Michigan Dental School.

Minnesota A pilot study is being made by Dr. Knutson, of the United States Public Health Service, on the topical application in a 2 per cent solution of sodium fluoride in 289 school children. Three other studies are being carried on along the same lines by the Department of Public Health in the towns of Hibbing, Chisholm and Virginia.

Mississippi Preliminary studies are being carried on by Dr. Hagan, of the United States Public Health Service, in two counties on the effectiveness of topical applications of sodium fluoride.

Nebraska Studies were made on the relation of *B. acidophilus* to dental caries at Boys' Town.

Nevada A preliminary study is being made of the production of dental fluorosis by varying high percentages of fluorine in the water supply.

New Hampshire Two demonstrations are in progress on the topical application of fluoride to tooth structures.

New York The State Department of Health is conducting a pilot program in the utilization of 1 p.p.m. of fluorine in the public water supply of Newburgh. Kingston, across the Hudson River, is used as the control community. Other projects in fluoride therapy are contemplated.

Ohio The United States Public Health Service has been conducting a fluorine project in Garrettsville for the last five years. Fluoride has been added to the water supply in this community. A fluorine study is being conducted in Miami

County by the United States Public Health Service, this will include topical applications of sodium fluoride.

Oklahoma Investigations are being conducted of the value of ammoniacal silver nitrate precipitated with eugenol as a means of controlling incipient caries. The program is both remedial and preventive.

Pennsylvania Two limited programs are being conducted on the topical effects of sodium fluoride.

Rhode Island Studies are being initiated in the topical effect of sodium fluoride at the St. Aloysius Orphanage, with the use of a 2 per cent solution of sodium fluoride, and by the Abby Frances Lawton Dental Clinic in Central Falls, under Dr. Bibby's direction. In West Warwick (20,000 population) there is a projected study of all school children in relation to the attack rate of caries and the introduction of fluorine into the water supply.

Texas Marshall is adding 1 p.p.m. of fluorine to the public water supplies. Jacksonville will be used as a control. This is a pilot program.

Washington The Washington Department of Health is offering laboratory service to private practitioners for counts of *B. acidophilus* and is making a study of diet in relation to the control of dental caries.

West Virginia The West Virginia Department of Public Health has suggested a technic to dentists in the topical application of sodium fluoride.

Wisconsin Preliminary surveys were made to determine the prevalence of dental caries. Further work is progressing on a comparison of the incidence of caries among kindergarten children in two cities—Green Bay, with a fluorine content of 2.3 p.p.m. in the water supply, and Sheboygan, with 0.05 p.p.m. Sheboygan proposes to add fluorine to the water supply. Other studies of long duration are contemplated.

Canada A study is in progress in Alberta on the relation of mottling of enamel to the low incidence of dental decay. In Ontario, the Department of Health, in co-operation with the Research Department of the Faculty of Dentistry, University of Toronto, is making water analyses and surveys to ascertain the incidence of dental caries. Dental surveys were conducted in two fluorine-free municipalities. Following the survey, one of the municipalities introduced fluoride into the water supply.

The assistance of the staff of the Massachusetts Department of Public Health, particularly Mr. Arthur D. Weston, Dr. Roy F. Feemster and Dr. A. Laurence Corbman, as well as that of Dr. Basil G. Bibby, dean of Tufts College Dental School, and of Dr. Abraham E. Nizel, is gratefully acknowledged.

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

CASE 32241

PRESENTATION OF CASE

A forty-nine-year-old housewife entered the hospital because of cramps in the legs and carpopedal spasm.

The patient had apparently been well until three days before entry, when she noticed cramps in the calves of both legs, which gradually increased in severity. She also became nauseated, vomiting several times. The following day the vomiting became worse, and she took bicarbonate of soda, which apparently gave some relief. On the afternoon of admission she first noticed spasms causing the hands to flex sharply. This was accompanied by a sensation of "pins and needles" in the arm muscles but no pain.

The patient had passed a total of only 500 cc of urine since the onset of her illness, although she had frequency of six or seven times a day and two or three times a night. A urinalysis by a local doctor on the day before entry had shown the urine to be heavy in albumin. The last adequate urine output was four days before entry. There was no history of any other urinary symptoms, although her husband stated that during the previous nine months she had occasionally complained of pain in the left groin and flank. There had been no chronic illness, weight loss, headache, stiff neck or food poisoning. The only drugs she recalled taking recently were stilbestrol, occasional small amounts of phenobarbital, aspirin and Karoid with bile salts.

In the past her health had always been excellent. Her two pregnancies were uncomplicated. She was treated at this hospital for a fistula-in-ano nine years before entry, when the urine showed a ++ test for albumin, with 150 white cells per high-power field, and a specific gravity of 1.026. A year later the specific gravity was 1.027, with eight white cells per high-power field and a + test for albumin. The fistula healed satisfactorily.

Physical examination revealed a flushed, drowsy, moderately obese woman who lay quietly in bed but appeared to be in considerable discomfort. She

breathed slowly and quietly. The heart, lungs, and abdomen were normal. The hands showed carpopedal spasm. The calves were tender to compression. There was a strikingly active Chvostek sign. The tendon reflexes were somewhat hyperactive. There was no uremic odor to the breath and no peripheral edema.

The temperature, pulse and respirations were normal, the blood pressure was 135 systolic, 85 diastolic.

Examination of the blood revealed a hemoglobin of 12 gm and hematocrit of 39. The white-cell count was 5200. The nonprotein nitrogen was 136 mg per 100 cc, rising to 145 mg the next day. The serum sodium was 136 milliequiv per liter, the chloride 85 milliequiv, the cholesterol 121 mg per 100 cc, the carbon dioxide content 27.7 milliequiv per liter, the alkaline phosphatase 2 Bodansky units, the phosphorus 9 mg per 100 cc, the calcium 5 mg and the serum protein 5.4 gm. A catheterized urine specimen (only a few cubic centimeters) was amber colored and clear, with a pH of 5.5. There was a ++++ test for albumin. The sediment contained rare red cells, 75 white cells, a moderate number of epithelial cells and many granular casts per high-power field. The Sulzowitch test for urinary calcium was positive, and a stool examination was guaiac negative. Repeated urine cultures showed moderate to abundant growth of *Staphylococcus albus*.

A cystoscopy and right retrograde pyelography were negative. An x-ray examination of the chest and abdomen was negative.

The patient appeared markedly improved after intravenous calcium gluconate but despite intravenous saline and glucose failed to pass more than a few cubic centimeters of urine at a time. After cystoscopy the urine became grossly bloody. Penicillin effected no improvement. The nonprotein nitrogen continued to rise, reaching 225 mg per 100 cc on the fifth hospital day, when peritoneal lavage with a solution of glucose, sodium chloride, sodium lactate and gelatin was instituted at the rate of about thirty liters a day. By the eighth hospital day the nonprotein nitrogen had dropped to 115 mg per 100 cc, but the temperature began to rise, and the patient developed a cough productive of small amounts of tenacious mucus. On the tenth hospital day she became disoriented and restless, and the temperature spiked to 105°F. On the ninth hospital day the abdomen was found to be distended and tender, although not particularly rigid. A few rhonchi were heard at the lung bases, and there was a pericardial friction rub. The blood pressure had dropped to 60 systolic, 35 diastolic. Abundant colon bacilli and nonhemolytic streptococci were grown from the peritoneal lavage fluid. The nonprotein nitrogen was 78 mg per 100 cc. Despite continued administration of penicillin, the patient died on the eleventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR. BERNARD JACOBSON May we see the films of the pyelogram?

DR. TRACY B. MALLORY There is no roentgenologist here, but Dr. Lingley reports that the films are entirely negative.

DR. JACOBSON To me, at least, one of the most disappointing findings in this case is the normal pyelogram. It upsets a good many possibilities that I should like to entertain. There is no evidence of any postrenal obstruction. I assume that the findings on the left side would have been similar had a left retrograde pyelogram been done. It looks like a good x-ray film to me. Do you agree, Dr. Colby?

DR. FLETCHER COLBY We did not do a bilateral pyelogram because the patient was in a precarious state at that time. We were interested in demonstrating, if we could, the presence of at least one normal kidney, which we succeeded in doing. This pyelogram was interpreted as being entirely normal.

DR. ALLAN M. BUTLER The history mentions pain in the left groin and flank. In view of the history I should like to know why a right pyelogram was done.

DR. COLBY At that time I did not know of the pain in the left groin and flank.

DR. JACOBSON To go back to the case, it is of interest that the duration of the whole illness prior to entry was three or four days after the onset of clinical tetany and oliguria. There is no question that the patient had some type of renal insufficiency with other complications later. This certainly is not an orthodox case of diffuse renal failure. There are many things lacking for a positive diagnosis of terminal chronic glomerulonephritis or chronic vascular nephritis, such as the absence of history of previous acute or chronic vascular renal disease. The patient had normal blood pressure. Many usual symptoms of uremia were absent. It is significant that she had a normal carbon dioxide content of the blood and no clinical or chemical evidence of acidosis. It is also important that she had a normal fixed base, a normal sodium in the blood, which is not an ordinary finding in uremia due to diffuse renal disease.

The first thing that struck me as unusual, regardless of the cause of renal insufficiency, was the presence of marked tetany in association with an extremely low blood calcium and extremely high blood phosphorus. This is a combination that I have never seen in renal insufficiency. It is true that the serum calcium sometimes falls slightly in ordinary renal failure, it may fall to 9.0, 8.5 or 8.0 mg per 100 cc. I have never seen it fall in renal failure to a tetanic level. The rise of the phosphorus, of course, can be entirely due to phosphorus retention by insufficient kidneys. On the other hand the presence of a positive Sulkowitch test, which means an excess of calcium excretion in the urine, is a

stumbling block in trying to explain the whole metabolic set-up. With a mild degree of hypocalcemia, of chronic terminal nephritis, the calcium excretion is either unchanged or is lowered as pointed out by Albright and Bauer¹ many years ago. Could this degree of hypocalcemia be related to the lowering of the serum protein? In cases of renal insufficiency accompanied by mild hypocalcemia, it is thought that the depression is due to or related to the slight depression of serum protein, but in this particular case the lowering to 5.2 gm does not seem adequate to explain the marked hypocalcemia. I should estimate with this degree of hypoproteinemia that the calcium might otherwise be lowered to approximately 8.5 mg, calculating about 2.0 mg attached to protein. So far as I can see there is only one known entity in which this type of calcium and phosphorus and clinical tetany can fit properly, and that is hypoparathyroidism. On the other hand, the positive Sulkowitch test is against that diagnosis, because in real hypoparathyroidism, with tetany, the calcium excretion in the urine goes down very markedly. I think the degree of hypocalcemia and the tetany make it likely that this patient had hypoparathyroidism rather than the hypocalcemia of renal failure.

The onset of oliguria suggests that renal insufficiency, with deficiency of renal secretion, had occurred, and it is worth while to consider the various causes of failure of renal secretion. Defective renal secretion is often seen in clinical shock and in conditions of severe dehydration, that is, prerenal failure, when there is not enough blood circulating to the kidneys to secrete urine. There is no evidence of postrenal failure. No lesion in the ureters or pelves that is obstructing the outflow of urine can be demonstrated.

What are the possible intrinsic renal causes of failure of renal secretion? The most frequent cause is some type of tubular obstruction or, in these days, poisoning from the administration of sulfonamides. Poisoning of the tubules with mercury can produce a somewhat similar picture. There is no evidence that the patient had an incompatible transfusion, with the precipitation of hemoglobin in the tubules, or that she had precipitated Bence-Jones protein in the tubules. We are told that so far as could be ascertained the patient had recently taken some stilbestrol, phenobarbital, aspirin, and Karoid with bile salts. So far as I know there is nothing in these drugs to produce tubular obstruction. In view of the fact that she had had some urinary-tract infection over a period of years one wonders whether she had not been given sulfadiazine or sulfathiazole prior to the onset of this illness. We have no evidence of sulfonamide administration in this case.

We must boil down this type of renal failure to something. Could this possibly be the terminal stage of chronic pyelonephritis? There are many

things against and a few things suggestive of this possibility. Against the diagnosis is the fact that this woman had been well, with no long history of symptomatic urinary-tract infection. On the other hand we know that at least nine years previously she had a moderate amount of urinary-tract infection. I suspect that at that time the urinary findings with high-specific gravity of 1.026 represented cystitis. There is no evidence of an infectious renal lesion, such as tuberculosis, or, at the time of entry, of generalized sepsis that might have terminated in multiple renal abscesses. Against the diagnosis of chronic pyelonephritis is the normal pyelogram and, possibly, the absence of leukocytosis. For the diagnosis of pyelonephritis, however, we have three points: at least nine years previously she was known to have a urinary-tract infection, for about nine months prior to entry she was said to have some pain in the left flank, and finally, the urinary sediment at the time of admission consisted mainly of white cells and granular casts consistent with the picture of pyelonephritis. We are told that the one small specimen of urine observed was amber in color. That would suggest a specific gravity much higher than that found in secondary renal failure.

This patient undoubtedly died partly because of a complication of the treatment. Most of us have read a fairly recent clinical report in the *Journal of the American Medical Association* by Fine et al.² on the removal of nitrogenous bodies in the blood by lavage of the peritoneal cavity, using the peritoneal cavity as a dialyzing membrane. That was obviously attempted in this case. That dialysis did something is evidenced by the fact that the blood nonprotein nitrogen dropped considerably. The patient did not die with the clinical picture of uremia. On the other hand the increasing abdominal distention and tenderness certainly suggest the onset of generalized peritonitis, and later we are told that colon bacilli and nonhemolytic streptococci were grown from the lavage fluid.

She had some type of pulmonary complication terminally, probably bronchopneumonia, and undoubtedly had generalized sepsis terminally. I have mentioned many of the stumbling blocks that I have tried to circumvent, and I am afraid I am forced to forget one thing: the positive Sulkowitch test, which does not agree with anything. It is possible that calcium or milk was administered shortly before the urine was tested for calcium. For want of a better diagnosis I shall rest on the following: idiopathic hypoparathyroidism, pyelonephritis (*Staphylococcus albus*), generalized peritonitis, bronchopneumonia and terminal pericarditis.

DR. MALLORY: Would anyone like to ask any questions of Dr. Jacobson, or does anyone wish to suggest any other diagnosis?

DR. JACOB LERMAN: I recall a patient who had a diffuse pyelonephritis with tetany and another

several years back, and I am sure that in Dr. Albright's series we could find several other examples.

DR. BUTLER: I do not see how Dr. Jacobson can entertain the diagnosis of hypoparathyroidism in this case with a nonprotein nitrogen of 136 mg per 100 cc, going up to 225 mg, unless the patient when she came in was extremely dehydrated and the degree of dehydration overlooked. The statement is made that she was moderately obese, and obesity often obscures dehydration. What evidence have we concerning the degree of dehydration that resulted from this woman's vomiting prior to entry?

DR. CHARLES BURNETT: She was not particularly dehydrated on entry.

DR. JACOBSON: May I ask Dr. Butler if he believes that the degree of abnormality of calcium and phosphorus in the blood is compatible with nothing but renal insufficiency?

DR. BUTLER: I think that is compatible with renal insufficiency. It is not unusual to find a serum calcium of 5.0 mg per 100 cc with a serum protein of 5.4 gm, and an inorganic phosphorus of 9.0 mg in a patient with marked renal insufficiency and elevated nonprotein nitrogen. Unless the patient was severely dehydrated I do not see how the elevation of the serum nonprotein nitrogen could be compatible with hypoparathyroidism.

DR. JACOBSON: I do not believe that such a degree of hypocalcemia in uremia is usual in adults.

DR. BUTLER: I have seen at least six patients on the adult wards of this hospital with this degree of hypocalcemia in uremia. I am still puzzled about the retrograde cystoscopic examination, puzzled in two respects. First, here is a patient who was having frequency rather than polyuria. Until we got the cystoscopic examination we suspected that a patient of this age with frequency and a history of renal infection might have cystitis but the cystoscopic examination was against it.

DR. COLBY: She had no evidence of cystitis from the examination of the bladder.

DR. BUTLER: In the hypocalcemia of hypoparathyroidism one gets bladder retention, not frequency. There was a history of frequency and not of bladder retention, which I think is against the hypocalcemia of hypoparathyroidism.

The second thing in the retrograde pyelogram that bothers me is why, if one subjected the left ureter to the trauma of putting a catheter up, one was too timid to inject a little dye to see what the left pelvis looked like. That was the kidney concerning which there was a history of pain.

DR. COLBY: Perhaps we were timid about this. On the other hand simultaneous injection of dye to both kidneys has been found dangerous. This woman was passing a small trickle of urine, and I suppose we believed that if we did a bilateral pyelogram and the trickle completely stopped we should think that there was a possibility of having caused complete anuria by this procedure.

DR. MALLORY Dr. Burnett, will you give us the clinicians' impression on the ward about this patient?

DR. BURNETT After repeated questioning we believed that we had ruled out any toxic substance. There was no history of the taking of mercury. We also considered sulfonamides, and repeated questioning during life gave no leads whatever. Our opinion at the time of death was that we were dealing with a bilateral nephrosis of the kidneys. We simply did not know why she had an acute renal shutdown. Subsequent to death we got an additional history that some time during the winter before admission the patient took 6 or 8 gm. of a sulfonamide, probably sulfadiazine. There was a considerable amount of the drug around the house that the family took from time to time, although there was no definite history that she took it before her illness.

CLINICAL DIAGNOSIS

Acute uremia due to idiopathic renal disease

DR. JACOBSON'S DIAGNOSES

Idiopathic hypoparathyroidism
Pyelonephritis (*Staphylococcus albus*)
Generalized peritonitis
Bronchopneumonia
Terminal pericarditis

ANATOMICAL DIAGNOSES

Sulfonamide nephrosis.
General peritonitis.

PATHOLOGICAL DISCUSSION

DR. MALLORY The autopsy, unfortunately, was limited to the examination of the kidneys. We cannot tell you anything about the parathyroid glands. At autopsy the kidneys looked remarkably normal for a woman who had been totally anuric for two weeks. On cutting frozen sections, however, it became evident that all the lower nephron segments were filled with pigmented casts, that there was interstitial inflammation and that there were crystals in some of the tubules that closely resembled sulfonamide crystals. To check the last point, a portion of one kidney was sent to the Chemistry Laboratory, and the material was identified as sulfadiazine. In spite of the negative history we thus have proof that she had ingested some amount of sulfadiazine. The other ordinary causes of lower-nephron nephrosis are absent in this case. There was no blood transfusion, no history of any state of shock, and no extreme dehydration. We know that sulfonamides can produce this lesion. The logical conclusion is that we consider this sulfonamide nephrosis, presumably due to an abnormal sensitivity of this particular patient to the drug.

DR. JACOBSON Was there peritonitis?

DR. MALLORY The immediate cause of death was peritonitis.

DR. JACOBSON How do you explain the normal carbon dioxide content, Dr. Butler?

DR. BUTLER I think it can be explained by the fact that she had been vomiting prior to coming to the hospital and had been taking alkalis. Without the vomiting and without the alkalis the anuria would have been accompanied by acidosis. She came in with a low serum chloride and normal carbon dioxide content, because of the coincidental vomiting and ingestion of alkali.

CASE 32242

PRESENTATION OF CASE

A sixty-year-old man entered the hospital because of difficulty in swallowing.

Two years before admission the patient allegedly vomited about two spoonfuls of bright-red blood. Shortly thereafter he noticed difficulty in swallowing meat, which "got down to the stomach and came right up again." Over a period of a year and a half the difficulty progressed to include all solid foods and then semisolid food until six months before admission, when it became impossible for him to swallow anything but fluids. His diet consisted of ice cream, milk, soup, eggnog, beer and whiskey. The last two items had been a dietary staple for many years, with an estimated daily intake of three or four glasses of whiskey and several glasses of beer. With this illness the patient lost 25 to 35 pounds. He felt weak and hungry, but had no pain or recurrence of hematemesis. The stools had never been black.

Physical examination revealed a thin, pale man, whose skin was hanging in loose folds in many areas. The tongue was coated with caked brown material. The abdomen was soft and flabby. The liver edge extended 5 cm. below the rib margin and was not tender. There were external hemorrhoids. The prostate was small and tender.

The temperature was 98.6°F, the pulse 70, and the respirations 20. The blood pressure was 110 systolic, 75 diastolic.

The red-cell count was 4,030,000, with 12.5 gm. of hemoglobin. The white-cell count was 7800, with 80 per cent neutrophils. The urine had a specific

gravity of 1.014, and the sediment contained 4 white cells and 2 red cells per high-power field. A stool was guaiac negative.

X-ray examination of the esophagus showed an area of constriction at the level of the tenth thoracic vertebra. A hiatus hernia of moderate size was present. The junction between the esophagus and the hernia was markedly constricted, and one area strongly suggested an ulcer crater (Fig. 1). The stomach was normal, but the duodenal cap was deformed. No definite crater was demonstrated. In the chest film the lung fields were bright. The heart was normal in size.

The prothrombin time was 27 seconds (normal, 21 to 25 seconds). The total serum protein was 7.7 gm. per 100 cc., with 5.3 gm. of albumin and 2.4 gm. of globulin. The van den Bergh reaction was normal,

FIGURE 1

but the cephalin-flocculation test was + at twenty-four hours and +++ at forty-eight hours. The nonprotein nitrogen was 26 mg. per 100 cc.

An operation was performed on the thirteenth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD B. BENEDICT When any man of sixty comes in with difficulty in swallowing, we ought first to consider carcinoma of the esophagus. This patient is within the age group. On the other hand, two years' duration is a little long, although I have seen carcinoma of that duration.

The vomiting of blood goes with carcinoma, benign stricture, esophageal ulcer or esophagitis. Benign stricture is the second thing I should consider in a patient who has difficulty in swallowing.

Patients cannot always tell how far a piece of food goes down, but it is fairly significant if it comes up immediately.

This patient did not have much of a diet, he must have been malnourished. Beer and whiskey may be taken by a patient with either carcinoma or benign stricture, but I must say that excessive use of alcohol may lead to an esophagitis and possibly esophageal ulcer and stricture.

The weight loss does not help. One can lose weight from carcinoma or esophageal obstruction from low intake of food. Pain is more likely in esophagitis and ulcer than in cancer of the esophagus; in cancer, pain appears rather late.

The enlarged liver makes me think of either metastatic cancer or cirrhosis because of the alcoholic history.

Out of 45 cases of benign stricture of the esophagus that I have looked up, 17 were associated with hiatus hernia, 15 with duodenal ulcer, 8 with esophageal ulcer, and 7 with esophagitis without any of these other factors, which may occur singly or multiply. This patient had hiatus hernia, possibly with esophageal ulcer and evidence of old duodenal ulcer, all of which are consistent with a benign stricture. May we see the x-ray films?

DR. JAMES R. LINGLEY I think that the spot films demonstrate the area in the esophagus best. This is the area of narrowing and the esophagus above this point is dilated. The margin comes down to a small taper rather than a shelf. Below the area of constriction one can see gastric mucosa. Evidently the hiatus hernia extends well up to the area of narrowing. On two of the films there is slight pooling of barium at this point, which is consistent with superficial ulceration, although that is not too definite. This is the deformity of the duodenum, there is gross deformity and constriction at the apex of the cap, without a definite crater.

DR. BENEDICT You do not see any suggestion of a shelf at that point either?

DR. LINGLEY No, it is a smooth, tapering shadow.

DR. BENEDICT All the laboratory findings were within normal limits. The cephalin-flocculation test was + at twenty-four hours, which means very little, and +++ at forty-eight hours, which is not sig-

nificant either. So far as liver damage is concerned, none of the tests indicate whether we are dealing with cirrhosis or metastatic cancer of the liver, if either.

I should hope that the operation performed was an esophagoscopy, which is the first thing to do, not only for positive diagnosis by biopsy but also for treatment by bougienage if a benign stricture is found. The treatment of benign stricture of the esophagus by esophagoscopy and bougienage is unusually satisfactory. I saw a recent case of esophageal obstruction with carcinoma of the esophagus and a large liver, which we thought was metastatic carcinoma of the liver and which proved on peritoneoscopy to be cirrhosis. If this case was carcinoma of the esophagus, which I do not think it was, there could have been metastases to the liver. I believe that it was a benign stricture of the esophagus, and the patient may have had early cirrhosis of the liver. My diagnosis is therefore benign stricture of the esophagus, in association with hiatus hernia, esophageal ulcer and duodenal ulcer, and question of cirrhosis of the liver.

DR. F. DENNETTE ADAMS: Is it not simpler to explain the large liver by malnutrition and the rigid feeling in the abdomen by the fact that the patient was formerly fat and had become extremely thin?

DR. RODOLFO E. HERRERA: As I remember it, Dr. Sweet and I thought that this man had a duodenal ulcer, short esophagus and hiatus-hernia syndrome, so that preoperatively we were quite certain that it was a benign stricture, but because of the question of ulcer of the esophagus and the amount of stenosis, we believed that he probably could be cured more permanently and more quickly if he were operated on than if he had bougienage for a long time. At operation a markedly stenosed short esophagus was found, and as is frequently noted it was difficult to visualize how this condition might have been treated successfully with repeated dilatations alone. The patient had a resection of the lower esophagus and a portion of the cardia and an esophagogastric anastomosis. The patient did extremely well. The postoperative course was uneventful. He was discharged on a six-meal bland diet.

CLINICAL DIAGNOSIS

Benign stricture of esophagus

DR. BENEDICT'S DIAGNOSES

Benign stricture of esophagus
Hiatus hernia
Esophageal ulcer
Duodenal ulcer
Cirrhosis of liver?

ANATOMICAL DIAGNOSIS

Benign stricture of esophagus

PATHOLOGICAL DISCUSSION

DR. TRACY F. MALLORY: The specimen from this patient consisted of 6 cm. of esophagus in addition to a cuff from the cardia of the stomach. At about the mid-portion of the esophageal segment, there was a short constriction 6 mm. in length where the lumen was reduced to a bare $\frac{1}{4}$ mm. in diameter. The mucosa was smooth and not ulcerated at any point. The sections through the area of constriction showed only nonspecific inflammatory reaction and fibrosis, an entirely benign lesion. There was nothing in the section that would give one any indication of the cause of the stricture.

DR. RICHARD H. SWEET: Was there any evidence of gastric mucosa?

DR. MALLORY: Not in this case.

DR. HERRERA: I have seen this patient once in the Out-Patient Department. Six months after operation he is back to his old diet, including whiskey and beer, and has told me that he has begun again to have some difficulty in swallowing large pieces of solid food. He was referred to the diet kitchen for a six-meal bland diet, to the X-ray department for further study and to Dr. Benedict for esophagoscopy.

Dr. Sweet might like to comment on the few cases we have seen of gastrointestinal symptoms following resection of the esophagus for inflammatory disease.

DR. SWEET: As Dr. Benedict has pointed out, a short esophagus with ulcer, inflammatory changes and stricture is frequently associated with a hiatus hernia and a duodenal ulcer. The short esophagus and the hiatus hernia I believe to be congenital. There is a difference of opinion regarding etiology. I can never see how an inflammatory stricture, which is often confined only to a short length up and down the esophagus, can pull the cardia 10 or 12 cm. out of the abdomen into the chest. Some of the cardias are as high as the inferior pulmonary vein. I do not know why we hurried over the esophagoscopy at this time unless it was that Dr. Benedict was not here. We have had cases in which the hazards of esophagoscopy were considerable, and I might have decided in his absence not to do it. I am not quite prepared to make a definite statement about this, but I have the distinct impression that there is a high incidence of carcinoma in cases of short esophagus. I shall say it this way: a large number of our cases of carcinoma at the lower end of the esophagus have been seen with this anatomical stricture. In one of Dr. McKittrick's patients on whom he asked me to operate, around the corner at the lower end of the gastric side, far beyond the reach of any instrument, there was in addition to this inflammatory stricture a carcinoma as large as a cherry. It is an interesting group of cases. Another point is that I agree with Dr. Bene-

dict that in all these cases bougienage should be attempted if carcinoma can be excluded. We have not always been able to carry out bougienage. I remember one patient who was transferred to the psychiatric ward because when his wife came to visit him his swallowing difficulty was worse. He ended up with carcinoma and, after we had watched him on the wards for a number of months, was completely inoperable. It did not do him any good to be on the psychiatric ward. We must be extremely careful, and I prefer to err on the side of being radical in some of these cases.

As Dr. Herrera mentioned we have had one or two patients who have had recurrence of esophagitis following resection, possibly because we did not resect enough or possibly because of some inherent

tendency to develop esophagitis. We have another patient in the Baker Memorial Hospital whose esophagus Dr. Benedict is in the process of dilating following resection of an area of esophagitis with stricture. It is a condition that must be studied and worked on a great deal longer before the best methods of treatment are fully established.

DR. BENJAMIN CASTLEMAN: Do you ever see a peptic ulcer due to regurgitation of acid into the esophagus following resection of the lower esophagus?

DR. SWEET: We have seen one in a patient who had a gastrostomy.

DR. BENEDICT: That is the one I have just treated by esophagoscopy and bougienage.

ONE HUNDRED AND SIXTY-FIFTH ANNIVERSARY

THE one hundred and sixty-fifth anniversary of the Massachusetts Medical Society, held at the Hotel Statler, Boston, was a fitting celebration of the postwar resumption of the more or less normal activities of the Society. The total registration—1750—established an all-time high, which is surprising in view of the fact that many fellows, as well as many recent graduates who have postponed joining the Society, are still serving with the armed forces.

The annual meeting of the Council was presided over by the retiring president, Dr. Reginald Fitz, with his customary expertness. There were few controversial matters, and all recommendations by

standing and special committees, which at times had been amended by the Executive Committee, were adopted. The report of the Committee on Medical Education, which had been instructed to make a survey of the medical educational facilities available in New England, was of particular interest. Based on a factual study of correlated material from many sources, it was concluded that New England, at the moment, does not need a new medical school and that its present schools can meet the anticipated requirements for the next several years. The increasing activities of the Society were responsible for a request for an extraordinary appropriation to cover the cost of additional secretarial help, which was granted, by the Council. The officers elected for the current year are as follows: president, Dwight O'Hara, president-elect, Edward P. Bagge, vice-president, Isaac S. F. Dodd, secretary, Michael A. Tighe, treasurer, Eliot Hubbard, Jr.; assistant treasurer, Norman A. Welch, and orator, Leland S. McKittrick.

At the annual meeting of the Society, Dr. Fitz gave an excellent talk covering what had transpired during his year of office. After presentation of the incoming president and president-elect, Dr. Frank H. Lahey delivered the annual oration, which will appear in the June 20 issue of the *Journal*.

The annual dinner was attended by approximately 525 fellows and guests. The speakers, Dr. Roger I. Lee and Dr. Elmer S. Bagnall, ably discussed many matters that are of general interest to the medical profession, particularly those having to do with the health of the Nation.

The scientific sessions comprised many well conceived and well presented papers. The Shattuck Lecture was presented by Dr. John B. Youmans, professor of medicine, Vanderbilt University School of Medicine, and formerly colonel, M.C., A.U.S., and chief, Nutrition Branch, Office of the Surgeon General. This paper, entitled, "Nutrition and the War," appears elsewhere in this issue of the *Journal*.

The luncheon meetings of the sections were extremely well attended, as were both the scientific and the technical exhibits, which were excellent. Indeed, many of the exhibitors were enthusiastic over the number of fellows who had visited their booths.

Much of the success of the meeting is due to the diligence and efforts of Dr Roy J Heffernan and his committee and of Robert St B Boyd, the executive secretary. To them the Society should be duly grateful.

TETANUS PROPHYLAXIS AND TREATMENT

SUFFICIENT time has now elapsed since the termination of the military campaigns to permit a certain amount of stocktaking with respect to the efficacy of some of the procedures used in the medical departments of the armed forces. Brigadier Boyd¹ has now collected and analyzed the cases of tetanus that occurred in the British Army in the African and European theaters of war. His analysis, although based on only 103 cases, brings out many significant features concerning the value and relative importance of active and passive immunization against tetanus.

Boyd points out that the value of the use of prophylactic tetanus antitoxin for passive immunization was adequately demonstrated during World War I. At that time the incidence of clinical tetanus was reduced from a former rate of 8 cases per 1000 wounded to 1 per 1000 among those who received antitoxin within a reasonably short period after sustaining a wound. The average incidence of tetanus among British troops for the years 1914-1918 was 1.47 per 1000 wounded.

In World War II, about 90 per cent of the British troops received prophylactic tetanus toxoid injections. At first, two doses of 1 cc each were given six weeks apart. In January, 1941, the standard procedure was changed to include a third dose, and in November, 1942, an annual booster dose of 1 cc of toxoid came into use. Shortly before the invasion of Europe all members of the army groups received a booster dose. Passive immunity by the injection of 3000 units of antitoxin at weekly intervals for three doses after wounding was recommended for those who had not received active immunization, and a single similar dose was suggested for those who had received toxoid injections. In the United States Army only a booster dose of tetanus toxoid was generally used after wounds had been sustained.

The 103 cases of tetanus included 35 battle casualties, an incidence of 0.14 cases per 1000 casualties. The remaining cases comprised 18 non-battle casualties and 50 partisans and prisoners of war. Of the 35 cases among battle casualties, 16 were in men who, for some reason or other, had escaped active immunization. Indeed, considerable evidence was accumulated, pointing to the fact that clinical tetanus was rare among those who had been actively immunized. For example, among the British Expeditionary Force in Europe during 1939-1940, there were 7 cases of tetanus among the 10 per cent of troops who had not been immunized, whereas not a single case occurred among the 90 per cent who had been given toxoid. In another campaign, there were only 6 cases of tetanus among 103,343 wounded British troops, most of whom presumably had been immunized, whereas there were 25 cases among a small number of wounded prisoners taken during that campaign, none of whom had been actively immunized. As compared with 1.47 cases per 1000 in World War I, there were only 0.06 cases per 1000 in this war, a ratio of almost 25:1.

Further analysis of the possible causes of this marked reduction in incidence of tetanus left little room for doubt that only active immunization was responsible. Evidence was obtained that indicated that the low incidence of tetanus among the British Expeditionary Force in Belgium was not due to any peculiarity in the type of terrain in which the wounds were incurred. Thus, data unearthed in a captured German hospital in Brussels showed that there had been 100 cases of tetanus among unimmunized troops who were wounded in the same terrain in which no cases occurred among the British Expeditionary Forces. Prophylactic treatment with sulfa drugs and penicillin was likewise ruled out as a significant factor.

Several points concerning the effect of active immunization on the severity of the disease and on mortality were also brought out quite clearly from Boyd's study. In the first place, the crude mortality in all the clinical cases during this war was 46.6 per cent, which is practically the same as that observed in 1914-1918, when it was 50 per cent. The mortality was inversely proportional to the length of the incubation period, which reflects a

direct relation to the severity of infection. The case mortality among those who were protected by active immunization was almost identical with that among the unprotected. It is of interest to note, however, that there were no deaths among persons who had received two or more booster doses of toxoid.

Most important, however, was the bearing of previous active immunization with toxoid on the efficacy of passive immunity conferred by the prophylactic injection of antitoxin. Among those who had been actively immunized with toxoid there were 2 deaths in 11 cases (18 per cent) in which prophylactic antitoxin had been given, as compared with 9 deaths in 11 cases (82 per cent) in which such passive immunity had not been used. Among those not actively immunized, there were 10 deaths among 23 patients (44 per cent) who had received prophylactic tetanus antitoxin, and 19 deaths among 39 patients (49 per cent) who had not received antitoxin. In other words, passive protection with antitoxin administered soon after wounding did the most good in the persons who had previously been actively immunized with toxoid.

Pratt,² in reviewing the experiences with tetanus at the Children's Hospital in Boston noted that the severity of the disease was the most helpful factor in determining the outcome. As already noted, severity is inversely proportional to the length of the incubation period. In Boyd's study the incubation period in the actively immunized patients was significantly lower than that in those who had not been protected by toxoid. In the protected patients symptoms began in most cases before the tenth day, whereas in most of those who had not been actively immunized with toxoid the incubation period was more than ten days. This appears to indicate that it was necessary to have a much severer disease, in which toxin production occurred at a rapid rate, to break through the residual antibody resulting from the previous toxoid immunization. This breakthrough, moreover, had to take place before the stimulus to renewed antibody production had become effective enough to raise the antitoxin level to a protective value.

The number of cases in Boyd's study was inadequate for an analysis of the value of various therapeutic measures. Early and intensive treat-

ment with antitoxin seemed to be quite valuable. This was suggested by the fact that there were 7 deaths among 18 patients (39 per cent) who received 100,000 or more units within the first thirty-six hours of symptoms, as compared with 14 deaths among 20 patients (70 per cent) not so treated. No additional benefit could be definitely ascribed to penicillin, but this was difficult to assess in the few cases in which it had been used. The same is true in the cases in civilians recently reported by several authors.³⁻⁵

Boyd concluded that tetanus was not entirely prevented by active immunization, since there were 22 cases among actively immunized persons in his series. Furthermore, the case mortality in actively immunized individuals was not below the average, but he points out that most of the fatal cases occurred among colored troops. The mortality, however, was significantly lower in actively immunized persons who received prophylactic antitoxin. Also the duration of symptoms in actively immunized patients who survived was significantly lowered. Failures of active immunization were attributed to inadequate levels of antitoxin remaining in the blood at the time when the infection took place, and he believes that the best way to remedy this is by the use of prophylactic antitoxin rather than by giving a booster dose of toxoid, as recommended in the United States Army. To be effective in therapy, antitoxin must be given as early as possible, in large doses and intravenously. The experiences of the United States forces have not yet been reported, but there is reason to believe that they were at least as favorable as those of the British in spite of the fact that the use of antitoxin was not encouraged.

DEATH

ALLEY — Ernest J. Alley, M.D., of Billerica, died May 23. He was in his seventy-second year.

Dr. Alley received his degree from the University of Vermont College of Medicine in 1899.

His widow and two daughters survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

PSITTACOSIS

Recently a case of psittacosis was reported from the North Metropolitan Health District. Subsequent investigation of the possible sources of this disease led to birds and bird dealers in various sections of the Commonwealth. Inasmuch as the clinical appearance of psittacosis cannot readily be distinguished from that of so-called "virus pneumonia" (of which it is actually one form), there may be more psittacosis in Massachusetts than one suspects.

Birds in the possession of dealers and in private homes, which die of "unknown causes," or diarrhea or any disease characterized by coughing, should be packed in dry ice and sent by air mail to the National Institute of Health, Bethesda, Maryland, for study, with psittacosis in mind.

Samples of serum taken under aseptic precautions from patients who have been in contact with birds and who develop atypical or virus pneumonia should be sent to Dr. Karl F. Meyer, Hooper Foundation, San Francisco, California, for the psittacosis complement-fixation test.

CORRESPONDENCE

QUALITY OF MEDICAL CARE

To the Editor: In the April 25 issue of the *Journal* you print an excellent editorial concerning the quality of medical care. You say, in part: "many thousands of graduates of substandard schools are in active practice. Undoubtedly some of these physicians give better medical care than do certain graduates of approved schools." Mere graduation from an approved medical school is no guarantee of an efficient and up-to-date practitioner. You are more than right on both these counts. Many young men go in for medicine because they are forced to by their parents and not because they have any real call to practice medicine. Medicine not being their vocation, they amble through life making weak medical gestures. Some rich persons wish to have a doctor in the family and are willing to pay for the luxury, but the doctor does not amount to much because he does not have the soul of a practitioner. One requires a soul, courage and much more if he essays to succeed in a rural New England practice. Some graduates become so-called "institutional men"; they take salaried hospital jobs, knowing that they would go down swiftly out in the competitive field. Such men would simply dry up and blow away if they did not have a job or private means. They are in no sense practitioners.

Graduation from an unaccredited medical college in no way implies inferiority. It is well known that many of the graduates of the so-called "substandard" medical schools can leave many of their brethren far behind on all counts. It has been said that the top 20 per cent of the poorest medical schools are better informed than the lowest 20 per cent of the best medical school. I believe that this statement is unfair to the unaccredited medical schools and that their graduates rank higher. If graduation from small unaccredited medical schools implied inferiority, the world would never have heard of a lot of men whose names are outstanding in the history of medicine and surgery.

In your editorial you speak of a plan in Massachusetts whereby doctors will be admitted to certain privileges in hospitals, such as making rounds, attending clinics and doing other things to improve their education and abilities. This is sound, and I hope that it will come to pass, but as you say yourself some doctors will probably "scorn" to avail themselves of the hospital invitation. Since the American College

of Surgeons has definitely taken the ball away from other big medical associations and has imposed its imperious will on hospitals and countless doctors, the word "scorn" is the correct term. The College has imposed a sort of serfdom on the general run of the profession, something like the *osculum infame* of the ancient European guilds. It will be interesting to see how far they will get with it these days. They have done quite a lot so far, and all in name of "higher standards," "accrediting" or what have you. These terms are a few of the bludgeons held over the hapless heads of many institutions. This has been going on for years, and aside from exterminating a lot of their own brethren, it does not appear that they have accomplished a thing that could not have been done much better in another way. The net result seems to have been the scourging of a lot of hapless physicians and small colleges and hospitals.

The irregulars have increased immensely, indeed thousands of fine medical recruits have been driven into the ranks of the irregulars, where they practice about everything the regular doctor does and prosper apace. The witch hunt, which is still going on, has not bothered the irregular doctor, in fact it has been a boon to him. He has found out that laboratory work, physiotherapy, x-ray technique, minor surgery, sclerosing therapy, medical and surgical diathermy all lend themselves beautifully to office practice. If a case of serious illness comes up, a hospital contact is not difficult to make.

Your editorial states, "Recently graduated physicians shun small cities and rural communities." You bet they do. Why not? Why should a graduate from high school, college, medical school and hospital, with perhaps another stretch of postgraduate training, bury himself in the woods and snow drifts? He is a fool if he does. Our standards are not too low; they are too high, and there is too much stress on specialization. In this vicinity there are towns that had from two to four doctors from Revolutionary days up until a few years ago. Not now, your recent graduate fades gracefully. The big medical associations in their craze to raise standards have exterminated the sturdy, capable, general practitioner who formerly rode these hills.

GASTRIC SURGERY*

FRANK H. LAHEY, M.D.†

BOSTON

SINCE this paper is presented before and will be read largely by physicians interested in the general practice of medicine, in it I will try to cover briefly many of the conditions in which surgery is applicable in the stomach, duodenum and jejunum, and our experiences with them. The latter two structures will be included because their surgical management, either by subtotal gastrectomy or by gastroenterostomy, involves the stomach at the time of the primary surgical procedure and even more seriously involves it when secondary complications, such as gastrojejunal ulcer and gastrojejunocolic fistulas, occur.

HIATUS HERNIA

If we consider gastric lesions in relation to their anatomic level, and start with the cardia, we can first consider the question of hiatus hernia and, together with hiatus hernia, peptic ulcer of the lower end of the esophagus, which occasionally develops as a result of the hernia.

Hiatus hernia is by no means an uncommon lesion. It is characterized by digestive disturbances and by pain beneath the sternum easily confused with anginal pain. It varies in intensity from acute episodes when good-sized sections of the upper stomach are trapped and distended in the hiatus hernia to the very vague digestive symptoms and very moderate degrees of distress that are associated with small openings through which but small sections of the stomach protrude into the pleural cavity (Figs 1 and 2).

The management of most of these lesions has been successfully accomplished by the Gastroenterological Department of the clinic by medical measures.

Since most of the symptoms associated with hiatus hernia are the result of distention of the herniated portion of the stomach, nonoperative measures are directed largely toward the attainment of more normal digestive function and the avoidance of gastric distention. With the establishment of a careful dietary regimen and the avoidance of laxa-

tives, there have been few of these patients who have but moderate-sized hernias in whom it has not been possible, without surgical interference, to maintain reasonable digestive comfort and to overcome the substernal pain of which most of these patients complain.

We have in the past in a number of these cases attempted to obtain relief by phrenicotomy, but with increased experience in their nonoperative

FIGURE 1 Roentgenogram of a Small Hiatus Hernia Associated with a Congenitally Short Esophagus

management, this procedure has been rarely necessary, and in the cases in which it has been done it has not added significantly to the benefits that can be obtained by medical management alone.

In hiatus hernias with large defects in which good-sized portions of the stomach pass through the

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, June 18, at twelve noon. Dr. Samuel Proger will speak on the topic "Water Imbalance."

Physicians are cordially invited to attend.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, JUNE 20

FRIDAY, JUNE 21

*10-00 a.m.-12-00 p.m. Medical Staff Rounds—Peter Bent Brigham Hospital

TUESDAY, JUNE 25

12-00 m.-1-00 p.m. Dermatological Service, Grand Rounds. Amphitheater, Dowling Building Boston City Hospital

*12-15 m.-1-15 p.m. Clinicoröntgenological Conference—Peter Bent Brigham Hospital

WEDNESDAY, JUNE 26

*10-30-11-30 a.m. Medical Clinic, Isolation Building Amphitheatre Children's Hospital

(Notices continued on page xix)

well established that everyone should be on the lookout to diagnose carcinomas of the upper end of the stomach or lower end of the esophagus earlier than they have been diagnosed in the past. Carcinomas of the lower end of the esophagus and upper end of the stomach, on the basis of autopsy figures from large hospitals, represent 5 per cent of

surgery, have operated on most of these patients, the mortality has progressively diminished until it is now within very reasonable figures

GASTRIC ULCER

The problem of gastric ulcer is one that has occupied the attention of gastroenterologists and surgeons over a great many years, largely owing to the relation between gastric ulcer and gastric cancer

Over the past years we have taken the position that a great many gastric ulcers can be healed and will remain healed under medical management. We have demonstrated this to our satisfaction, and if one could be certain concerning his ability to determine safely which lesion is benign and which lesion is malignant, I should personally be willing to continue with this program. But now, at the end of several years' experience with this position, I believe that it should be changed to the position

FIGURE 4 Preoperative Roentgenogram of a Carcinoma of the Lower End of the Esophagus
This was resected transthoracically through the diaphragm, the stomach being pulled up into the chest and anastomosed to the esophagus to make up for the defect

all carcinomas found at autopsy. Over the years our attitude toward malignant lesions in this location has been so pessimistic that we have not concentrated sufficiently on their early diagnosis. With these lesions now so removable by means of radical surgery, the slightest feeling of discomfort in the lower esophagus, the most trivial degrees of obstruction and the most vague digestive symptoms must be thoroughly investigated with regard to the possibility of this lesion if we are to make full use of the surgical facilities now at hand in attempting to cure a greater number of these patients (Figs 4, 5 and 6)

Mortality figures in these patients submitted to resections of the lower end of the esophagus and upper end of the stomach are shown in Table I. It is to be noted that, with increasing experience in the hands of Dr. Ralph Adams and Dr. Herbert D. Adams, who, because of their interest in chest

FIGURE 5 Postoperative Roentgenogram after Transthoracic and Transdiaphragmatic Resection

that all gastric ulcers, provided the patient is a reasonably good risk, should be submitted to operation. This seems a radical position to take, particularly in the light of some of our previous statements, and some of our previous experiences with these lesions, which have healed under nonoperative management, but I have personally come to this conclusion for the following reason. The results in the surgical treatment of gastric cancers are so de-

diaphragm, repair of this defect has occasionally been necessary. It presents no technical problems of great difficulty except to be certain that the aperture is adequately closed without producing obstruction.

PEPTIC ULCER OF THE ESOPHAGUS

Dr. Donald T. Chamberlain¹ has reported from this clinic the occurrence of 7 peptic ulcers of the lower end of the esophagus. One of these was due to the occurrence of a peptic ulcer in aberrant gastric mucosa, the remainder were associated with and probably brought on by hiatus hernia.

These lesions are probably brought about by the congestion in the mucosa as the upper end of the stomach and lower end of the esophagus rub against the edge of the aperture in the diaphragm, together

or duodenum as shown by the roentgenogram, one must have in mind the possible presence of such a peptic ulcer in the esophagus.

Dr. Everett D. Kiefer, of the Gastroenterological Department of the clinic, has set up the criteria for the diagnosis of these lesions: there must be a high

FIGURE 2 Roentgenogram of a Sizable Hiatus Hernia above the Level of the Diaphragm.

It is quite well distended and in the state of distention that produces symptoms.

with the fact that in the trapped segment of stomach there occurs a high gastric acidity, thus providing favorable conditions — congestion associated with gastric contents having high acid values — for the production of a peptic ulcer. These are the conditions that, when brought about in experimental animals, make it possible to produce experimental peptic ulcer (Fig. 3).

In patients presenting typical ulcer symptoms with high acidity, hunger pain and food relief, and in the absence of any visible defect in the stomach

FIGURE 3 Roentgenogram of a Small Hiatus Hernia Associated with a Peptic Ulcer.

The ulcer is shown by the fleck at the point of the arrow. Note the relation of this ulcer to the diaphragm, which can be seen as a shadow. This patient was relieved of all symptoms by ulcer treatment.

gastric acid value, typical ulcer symptoms must be relieved by food and alkali, the ulcer must be visualized by esophagoscopy, and the symptoms must disappear after nonoperative ulcer management. All these patients have been successfully managed without operation, and the subject is discussed merely as a reminder of the occurrence of this lesion in a patient with ulcer symptoms but with no ulcer demonstrable in the usual locations.

CARCINOMA OF THE CARDIA AND LOWER ESOPHAGUS

One of the lesions that has now become surgically approachable is carcinoma of the cardiac end of the stomach, so often spreading over onto the lower end of the esophagus, or vice versa.

The surgical management of these lesions by means of the transthoracic approach has been so

well established that everyone should be on the lookout to diagnose carcinomas of the upper end of the stomach or lower end of the esophagus earlier than they have been diagnosed in the past. Carcinomas of the lower end of the esophagus and upper end of the stomach, on the basis of autopsy figures from large hospitals, represent 5 per cent of

surgery, have operated on most of these patients the mortality has progressively diminished until it is now within very reasonable figures

GASTRIC ULCER

that all gastric ulcers, provided the patient is a reasonably good risk, should be submitted to operation. This seems a radical position to take, particularly in the light of some of our previous statements, and some of our previous experiences with these lesions, which have healed under nonoperative management, but I have personally come to this conclusion for the following reason. The results in the surgical treatment of gastric cancers are so de-

pressing that there must be some radical change in our attempts to deal with them earlier if we hope to improve these results. It has now been demonstrated beyond reasonable doubt that even in the presence of gastric cancer, apparent healing of the ulcerating lesion can be brought about under good medical management. We have, in addition, in suspicious lesions found it difficult, and at times almost impossible, to make patients return a sufficient number of times for adequate check-up examinations to be certain that what appeared to be a benign lesion was not developing into a malignant

advising subtotal gastrectomy in all cases of gastric ulcer. In a large experience with these lesions, some mistakes have been made in diagnosing ulcer when carcinoma was present, and this, together with a recognition of the fact that nothing but a more aggressive approach to gastric lesions in the way of early radical surgery will improve a field that is now far from satisfactory, brings me to this position.

As already stated, gastric carcinoma is almost the most depressing situation in the entire field of readily approachable surgical lesions. This is

one. We have now done high subtotal gastrectomies on 85 consecutive patients with gastric ulcer with no mortality. In view of the above consideration, we believe that if this be balanced against the constant danger of wrongly diagnosing a gastric ulcer for early gastric cancer, better results will be obtained and greater progress will be made in the management of gastric cancer by the position of

primarily due to the fact that it is so rarely diagnosed early, which, in turn, is due to certain factors related to this lesion. It produces a low gastric acidity or an acidity and so does not produce the digestive symptoms related to high acidity, as occurs with ulcer; it is an infiltrating lesion and so does not produce early hematemesis; the stomach is of such size that the growth of the lesion produces obstructive symptoms only in the late stages of the disease. As a result of all these factors, the lesion may be fairly well advanced before it produces symptoms of an urgent and distinctive character.

In addition to the above factors, the high vascularity of the stomach, the rich field of lymphatics that surround it and the fact that it is a structure in which active and vigorous motion exists with great frequency produce conditions for early extension outside of the structure itself and result in recurrence today, in spite of radical operation, in over 90 per cent of cases.

To improve the results in carcinoma of the stomach will be difficult. It will involve requirements and conditions that are almost impossible to attain, that is, more complete and involved investigations for relatively minor symptoms, such as earlier gastric analyses, gastroscopies, fluoroscopies and roentgenograms, more frequent explorations of doubtful lesions and the more universal establishment of the position that I am now willing to take, namely, that all patients with gastric ulcer should be submitted to radical surgery.

The mortality figures for the last consecutive series of cases of peptic ulcer are submitted in Table 2, involving cases operated on in the last ten years.

GASTRIC CARCINOMA

Two types of operation are available for the management of gastric cancer—high subtotal gastrectomy and total gastrectomy combined with

splenectomy in order to make the total gastrectomy more radical and the anastomosis of the jejunum to the esophagus easier and safer under good direct vision, as can be done with the spleen removed.

Because palliative operations, such as palliative gastroenterostomy, are so unsatisfactory, are done so often in advanced lesions, provide relief for such a relatively short period of time and have such a high

involved nodes in the omentum, so frequently present in cases of carcinoma of the stomach, but also exposes the posterior wall of the stomach, the gastric artery at its root and the posterior wall of the duodenum so satisfactorily and adequately that it not only increases the radicalness of the procedure but makes it technically much easier to do.

LEIOMYOMA OF STOMACH

In Figure 8 is shown the roentgenogram of a patient with leiomyoma of the stomach and in Figure 9 is shown the specimen of such a case, removed by subtotal gastrectomy.

I wish particularly to call attention to this lesion, of which we have now had 14 cases. I am especially anxious to call attention to this group of cases because almost all these patients have a history of repeated hemorrhages. In the removed specimen (Fig. 9) will be seen the healed scars representing ulceration of the mucosa over this tumor.

Because of the fact that leiomyomas usually do not produce symptoms except for the frequently profuse hemorrhages that go with them, this bleeding is often suspected of being caused by ulcer and, unless adequate investigation is carried out, many of these patients are treated for ulcer because of the profuseness of the hemorrhage.

It is important that these cases be diagnosed early because of the fact, as I have stated in a previous article on this subject, that 71 per cent of these tumors, on removal, have shown sarcomatous degeneration. It is for this reason that I particularly wish to call attention to them and their need for early and radical removal.

There has been no mortality in this group of cases.

TOTAL GASTRECTOMY

Our oldest living patient on whom total gastrectomy was done was operated on October 8, 1937, for a large leiomyosarcoma involving all the stomach. She is, therefore, now alive and well eight years and seven months after operation. This operation, of which we have now done eighty-nine, is really a development of the last ten years. We have applied total gastrectomy in the cases of leiomyosarcoma in which it has the most favorable prospect of cure in that these lesions may involve the entire stomach but still remain of a relatively low grade of malignancy.

We have applied this operation also to the lymphosarcomas because of the fact that, with partial gastrectomy, it is difficult in many of these cases to determine the limit of infiltration because these lesions do not produce a true tumor, but are infiltrating in character. The oldest patient of this group is alive and well seven years and one month after total gastrectomy.

We have also applied this operation to the infiltrating type of carcinoma of the stomach to which

TABLE 2 Mortality for Cases of Peptic Ulcer (October 1, 1936, to April 1, 1946)

DIAGNOSIS	NO OF CASES	NO OF DEATHS	MORTALITY %
Duodenal ulcer	358	10	2.8
Gastric ulcer	65	0	0.0
Esophageal ulcer	67	1	1.5

mortality rate, we have been less and less interested in doing them. This has resulted in employing subtotal gastrectomy in many of the advanced cases of carcinoma of the stomach in which in the years gone by a palliative procedure, such as gastroenterostomy, would have been performed. This has been done on the basis that an operation in which the lesion itself is removed even when a cure cannot be anticipated is superior to a palliative gastroenterostomy in which the lesion is left behind, soon to invade the new stomach.

This approach results, as might be expected, in a relatively high mortality, 12 per cent in 256 consecutive cases, as may be seen from the statistics (Table 3). It is, however, superior to the palliative operation, in which the mortality is almost twice this figure, 21 per cent.

There are a few things that we have learned in our experience with subtotal gastrectomy for malignant tumors. One is that the operation can be made

TABLE 3 Mortality for Cases of Carcinoma of the Stomach (October 1, 1936, to April 1, 1946)

OPERATION	NO OF CASES	NO OF DEATHS	MORTALITY %
Subtotal gastrectomy	256	31	12.6
Exploration and biopsy	294	18	6.1
Palliative operation	66	14	21.1

more radical by combining omentumectomy with the subtotal gastrectomy, and the other is that to give these patients with malignancy a real chance, resection must be so high that it cannot be done with stomach clamps. For that reason, all subtotal gastrectomies performed at the clinic during the last eighteen years have been done with the von Petz sewing machine, making it possible to remove four fifths of the stomach in these cases, together with almost the entire omentum.

Omentumectomy, partial or complete, as shown in Figure 7, not only removes metastatically in-

pressing that there must be some radical change in our attempts to deal with them earlier if we hope to improve these results. It has now been demonstrated beyond reasonable doubt that even in the presence of gastric cancer, apparent healing of the ulcerating lesion can be brought about under good medical management. We have, in addition, in suspicious lesions found it difficult, and at times almost impossible, to make patients return a sufficient number of times for adequate check-up examinations to be certain that what appeared to be a benign lesion was not developing into a malignant

GASTRIC CARCINOMA

Two types of operation are available for the management of gastric cancer—high subtotal gastrectomy and total gastrectomy combined with

come sufficiently standardized in our hands and in the hands of many other surgeons so that it can be done with a reasonable mortality rate in spite of its magnitude, that patients can survive and live happily and maintain their weight and strength with no stomach and with the proximal loop of jejunum anastomosed to the esophagus serving as a substitute for a stomach and that it is necessary postoperatively throughout the remainder of their lives to keep close track of the blood picture in these patients, because of the tendency for anemias to occur. In almost all these cases it has been necessary for the patients to take liver, iron and vitamins. After operation, frequent meals must be

are as follows: 59.7 per cent have a chance of living for 12 months, 38.6 per cent for 18 months, 29.8 per cent for 24 months, and 21.1 per cent for 36 months or more.

DUODENAL ULCER

Duodenal ulcer is the most complicated lesion in my opinion in the entire field of gastric surgery. In this clinic over the past years we have had passed through the Gastroenterological Department for management 8000 patients with duodenal ulcer, of whom approximately 6 per cent have come to surgery. The mortality rate was 15 per cent, but as a result of the occurrence of 4 fatalities in the last year is now 2.8 per cent for the past ten years.

This lesion, exclusive of gastrojejunal colic fistula, has associated with it the highest mortality rate in the entire surgical management of peptic ulcer. It will be noted in the statistical chart (Table 2) that in a consecutive series of 85 cases of resection for gastric ulcer there was no mortality, and that the mortality in 87 consecutive cases of resection for jejunal ulcer, which involves not only subtotal gastrectomy but also resection of the jejunum, was 2.3 per cent, even lower than that for subtotal gastrectomy for duodenal ulcer.

In discussing this lesion and its surgical management, I have again and again stated that the mortality of duodenal ulcer is not the result of the subtotal gastrectomy but of the relation of the duodenal ulcer to the head of the pancreas, into which it so frequently erodes, and to the common bile duct, to which it is so often intimately attached by the induration and scarring associated with it.

We have taken the position over the years that, when possible with reasonable safety, we should always remove the duodenal ulcer and that part of the duodenum in which it occurs. We do not believe that the removal of the duodenal ulcer is essential to bring about a cure with subtotal gastrectomy, but that its removal is often essential if one wishes to obtain enough flexible duodenal stump so that it can be safely inverted without the danger of a duodenal fistula. It has been our desire to avoid the occurrence of a duodenal fistula, representing as it does leakage, the danger of digestion of the fistula wall and the always possible occurrence of a fatality. It is for this reason, not the mere removal of the ulcer, that we have advocated that, included in the subtotal gastrectomy for duodenal ulcer, whenever reasonably possible, should be the removal of that portion of the duodenum in which the ulcer is situated, together with the ulcer.

Working, as we do, in very close and intimate relation to the members of the Gastroenterological Department of the clinic, it must be realized that practically all patients with duodenal ulcer coming to the Surgical Department for subtotal gastrectomy have ulcers of the chronic, recurring type, intractable to medical management and often asso-

FIGURE 8 Roentgenogram of a Leiomyoma of the Stomach. This shows the typical roentgenographic defect seen with these lesions.

ciated with it — at least five a day — until at least a year or more has passed, by which time, in most of the cases, three meals of sufficient size can be taken at the regular intervals that have been established for all of us, and the interval feedings will not be necessary (Figs. 10 and 11).

Among the 89 cases of total gastrectomy there were 26 deaths, a mortality of 29.2 per cent, but of the patients operated on from January 1, 1942, through October 1, 1945, only 7 died, a mortality of 16.3 per cent*. The estimated chances of survival, based on 57 patients who survived operation and were followed, whether now living or dead,

*From follow up data compiled by Dr. Frances H. Smith, Department of Gastroenterology, Lahey Clinic (to be published).

the term "linitis plastica" has been given, owing to the fact that this type of cancer of the stomach, in contradistinction to the localized type, tends to spend its energy more largely in intramural infiltration than in local extension and metastases to the lymph nodes. The oldest patient of this group is now alive and well without recurrence five years and four months after operation.

As already stated, it is in the first group, the multiple leiomyosarcomas involving the entire stomach, that there is the greatest prospect of cure by total

Our position regarding the use of total gastrectomy, therefore, can be stated in the light of our experiences to date with 89 cases in which this operation has been done. Even in cases with complete involvement of the stomach by carcinoma of the linitis plastica type, life can be and has been prolonged from a few months to five years and four months. In the linitis plastica type of carcinoma of the stomach cures cannot be expected, but prolongation of life with comfortable living can be anticipated in many of the cases, if properly selected. In lei-

FIGURE 7

This illustration shows how the omentum can be separated from the transverse colon for omentectomy, together with subtotal or total gastrectomy, and also demonstrates exposure of the posterior wall, the gastric artery and the posterior wall of the duodenum (reproduced from Marshall² by permission of the publisher)

gastrectomy, and it is unlikely in the patients with carcinoma that there will be cases in which the lesions are so extensive that total gastrectomy is indicated in which permanent cures can be expected.

Although it is true that in the linitis plastica type of carcinoma of the stomach, obvious metastases to lymph nodes are often not apparent, it is in all probability equally true, in the cases in which the entire stomach is so involved that total gastrectomy is indicated, that there will be no cases in which some distant metastases have not already taken place and ultimate recurrence is inevitable.

myosarcomas there is a reasonable prospect of cure even when the lesions are extensive and total gastrectomies must be employed. Between the optimistic prospect concerning cure that one may have with patients who have leiomyosarcomas and the pessimistic ultimate prognosis in those in whom the linitis plastica type of carcinoma exists, rests lymphosarcoma of the stomach so far as the prospects of a satisfactory future life are concerned. This experience with total gastrectomy, as shown in our mortality figures, has permitted us to draw certain conclusions that the operation has now be-

come sufficiently standardized in our hands and in the hands of many other surgeons so that it can be done with a reasonable mortality rate in spite of its magnitude, that patients can survive and live happily and maintain their weight and strength with no stomach and with the proximal loop of jejunum anastomosed to the esophagus serving as a substitute for a stomach, and that it is necessary postoperatively throughout the remainder of their lives to keep close track of the blood picture in these patients, because of the tendency for anemias to occur. In almost all these cases it has been necessary for the patients to take liver, iron and vitamins. After operation, frequent meals must be

as follows: 59.7 per cent have a chance of living for 12 months, 38.6 per cent for 18 months, 29.8 per cent for 24 months, and 21.1 per cent for 36 months or more.

DUODENAL ULCER

Duodenal ulcer is the most complicated lesion in my opinion in the entire field of gastric surgery. In this clinic over the past years we have had passed through the Gastroenterological Department for management 8000 patients with duodenal ulcer, of whom approximately 6 per cent have come to surgery. The mortality rate was 1.5 per cent, but as a result of the occurrence of 4 fatalities in the last year is now 2.8 per cent for the past ten years.

This lesion, exclusive of gastrojejunal fistula, has associated with it the highest mortality rate in the entire surgical management of peptic ulcer. It will be noted in the statistical chart (Table 2) that in a consecutive series of 85 cases of resection for gastric ulcer there was no mortality, and that the mortality in 87 consecutive cases of resection for jejunal ulcer, which involves not only subtotal gastrectomy but also resection of the jejunum, was 2.3 per cent, even lower than that for subtotal gastrectomy for duodenal ulcer.

In discussing this lesion and its surgical management, I have again and again stated that the mortality of duodenal ulcer is not the result of the subtotal gastrectomy but of the relation of the duodenal ulcer to the head of the pancreas, into which it so frequently erodes, and to the common bile duct, to which it is so often intimately attached by the induration and scarring associated with it.

We have taken the position over the years that, when possible with reasonable safety, we should always remove the duodenal ulcer and that part of the duodenum in which it occurs. We do not believe that the removal of the duodenal ulcer is essential to bring about a cure with subtotal gastrectomy, but that its removal is often essential if one wishes to obtain enough flexible duodenal stump so that it can be safely inverted without the danger of a duodenal fistula. It has been our desire to avoid the occurrence of a duodenal fistula, representing as it does leakage, the danger of digestion of the fistula wall and the always possible occurrence of a fatality. It is for this reason, not the mere removal of the ulcer, that we have advocated that, included in the subtotal gastrectomy for duodenal ulcer, whenever reasonably possible, should be the removal of that portion of the duodenum in which the ulcer is situated, together with the ulcer.

Working, as we do, in very close and intimate relation to the members of the Gastroenterological Department of the clinic, it must be realized that practically all patients with duodenal ulcer coming to the Surgical Department for subtotal gastrectomy have ulcers of the chronic, recurring type, intractable to medical management and often asso-

ciated with complications, such as recurring hemorrhages or pyloric obstruction. This means that in a high percentage these patients on whom we do subtotal gastrectomy have badly scarred duodenal ulcers that have eroded into the head of the pancreas and into the pancreaticoduodenal artery, which runs on the back wall of the duodenum, and as a result of the induration and scarring, often have pyloric obstruction.

Over the years we have adhered quite strictly without much change to what we have published in

the hospital and in bed, where they have been relieved of emotional stress and strain, and by putting them on rigid dietary regimens and antispasmodics, with the result that in many cases the obstructions have been relieved, only to recur when the patients have resumed their work and activities under the stress and strain that frequently go with them, or when they have perhaps not adhered as rigidly to their dietary regimen as they should.

We have been disturbed at times by having to carry out surgical procedures on these patients late,

FIGURE 9 Gross Specimen of the Leiomyosarcoma
Note the scars of previous ulceration and hemorrhages, as mentioned in the text. Microscopically this proved to be a leiomyosarcoma.

the past as our indications for surgery in duodenal ulcer. They are as follows: failure to relieve distress and pain by medical management, the occurrence of hemorrhage, particularly repeated hemorrhages, in spite of medical management, perforation, obviously an emergency indication for operation, and pyloric obstruction. This set of indications is so straightforward that they require little further discussion, except perhaps the matter of pyloric obstruction and hemorrhage.

I have repeatedly said that in the past we have often wasted time and money of patients with recurring pyloric obstruction by getting them into

at which time we have often thought that we should have done the operations sooner. We have sought, therefore, a plan whereby we could make earlier decisions in the patients with pyloric obstruction, particularly those related to duodenal ulcer, concerning when we could expect that the pylorus that we are able to open would remain open, when it would not remain open and when surgery was indicated.

Dr S. Allen Wilkinson,⁴ in the Gastroenterological Department, has developed and published a plan that has been of great help to us in making this decision. It consists of putting an indwelling Levine tube in the patient's stomach through the nose,

feeding the patient who is known to have pyloric obstruction a 90-cc noncurdling mixture through

not decrease promptly within the three-day period from a high to a low figure, one can anticipate that

four hours. When, as shown in Table 4, which lists a few examples of such cases, the drainage does

open under medical management. Table 5 shows that in those patients who had pyloric obstruction

ciated with complications, such as recurring hemorrhages or pyloric obstruction. This means that in a high percentage these patients on whom we do subtotal gastrectomy have badly scarred duodenal ulcers that have eroded into the head of the pancreas and into the pancreaticoduodenal artery, which runs on the back wall of the duodenum, and as a result of the induration and scarring, often have pyloric obstruction.

Over the years we have adhered quite strictly without much change to what we have published in

the hospital and in bed, where they have been relieved of emotional stress and strain, and by putting them on rigid dietary regimens and antispasmodics, with the result that in many cases the obstructions have been relieved, only to recur when the patients have resumed their work and activities under the stress and strain that frequently go with them, or when they have perhaps not adhered as rigidly to their dietary regimen as they should.

We have been disturbed at times by having to carry out surgical procedures on these patients late,

FIGURE 9 Gross Specimen of the Leiomyosarcoma

Note the scars of previous ulceration and hemorrhages, as mentioned in the text. Microscopically this proved to be a leiomyosarcoma.

the past as our indications for surgery in duodenal ulcer. They are as follows: failure to relieve distress and pain by medical management, the occurrence of hemorrhage, particularly repeated hemorrhages, in spite of medical management, perforation, obviously an emergency indication for operation, and pyloric obstruction. This set of indications is so straightforward that they require little further discussion, except perhaps the matter of pyloric obstruction and hemorrhage.

I have repeatedly said that in the past we have often wasted time and money of patients with recurring pyloric obstruction by getting them into

at which time we have often thought that we should have done the operations sooner. We have sought, therefore, a plan whereby we could make earlier decisions in the patients with pyloric obstruction, particularly those related to duodenal ulcer, concerning when we could expect that the pylorus that we are able to open would remain open, when it would not remain open and when surgery was indicated.

Dr. S. Allen Wilkinson,⁴ in the Gastroenterological Department, has developed and published a plan that has been of great help to us in making this decision. It consists of putting an indwelling Levine tube in the patient's stomach through the nose,

feeding the patient who is known to have pyloric obstruction a 90-cc noncurdling mixture through not decrease promptly within the three-day period from a high to a low figure, one can anticipate that

*The figures represent the amounts on consecutive days

four hours. When, as shown in Table 4, which lists a few examples of such cases, the drainage does open under medical management. Table 5 shows that in those patients who had pyloric obstruction

for less than three months, 39 per cent⁴ required ultimate surgery, whereas of those who had pyloric obstruction three months or more, an increased percentage (69 per cent) ultimately required operation. This has proved a valuable procedure in our hands in saving patients time in the hospital and permitting us to arrive at an early decision in patients with pyloric obstruction concerning when operation was necessary.

One should not leave the matter of bleeding without again calling attention to the fact that there are two types of bleeding associated with duodenal

concerning whether radical operation is advisable. It is our opinion, as stated above, that when such a hemorrhage occurs in spite of a good regimen of medical management, subtotal gastrectomy is indicated.

It is to be remembered, however, that there is another rare but extremely dangerous type of hemorrhage associated with duodenal ulcer—that

ulcer. The more frequent one, that with which everyone is quite familiar, is the case with an occasional single hemorrhage from which, in spite of a considerable loss of blood, the patient promptly recovers. Many patients with peptic ulcer become callused to hemorrhages of this type and do not look on them with undue apprehension.

In this type of bleeding there is no surgical emergency and the decision can be made deliberately

is, the massive hemorrhage in which the bleeding persists and is of such magnitude and frequency as to result not infrequently in a fatality unless something desperate is done.

It is in these cases that an immediate decision must be made if these patients are to be saved. This decision must be made within forty-eight hours and often within twenty-four hours if, in spite of massive transfusions, one hopes to save these patients. It is to be remembered that hemorrhage is often more serious and fatal in patients over fifty years of age than in those under fifty years of age. This is not an easy decision to make, but in the presence of persisting and repeated hemorrhages from duodenal ulcers, where facilities and adequate experience are available, these patients should not be permitted to go on to such desperate states that ultimate surgery, when done, has little or no prospect of resulting in anything but a fatality.

Decision regarding what the approach to this serious problem is must remain in the judgment of the surgeon, based largely on what the patient will stand. In some of these cases we have saved the patient's life by subtotal gastrectomy, together with removal of the indurated ulcer, and control of the bleeding, even when the risk has been desperate. In others, so desperate has been the situation that we have opened the duodenum, transfixed the bleeding ulcer with silk and done a gastroenterostomy to overcome the obstruction that has resulted. The mortality in these cases will be high. In this selected group with recurring massive hemorrhages it is the only procedure, however heroic the measure may appear to be, that offers these patients a prospect of life.

As a result of this experience with subtotal gastrectomies for intractable duodenal ulcer, we can draw the following conclusions. The resection must be high (Figs 12 and 13) in order to get out the largest number of acid-bearing glands. Our resections

have taken out as a minimum three fourths and in most cases four fifths of the stomach, and when it is reasonably possible, it is desirable to remove the ulcer and that portion of the duodenum in which it is situated. An antecolic anastomosis without enteroenterostomy has in our hands been the most satisfactory method of restoring the intestinal stream, it is not desirable to do an enteroenterostomy between the afferent and efferent loops of jejunum because of the fact that it sidetracks alkali-

It is well to state to these patients that following subtotal gastrectomy they cannot eat anything they desire and cannot drink and smoke. If they wish to have the best prospect of nonrecurrence of their ulcers, in the form of gastrojejunal ulcers, they must remain on a postoperative diet that is almost as rigid as is the diet for the medical management of an ulcer that is to be treated without surgery. It must, I believe, be accepted that if a patient has once had an ulcer he is a prospect for

FIGURE 12 Roentgenograms in a Case of Duodenal Ulcer

line duodenal and jejunal contents beyond the stomach and prevents them from entering the stomach, as they do when no enteroenterostomy is done, thus helping to lower gastric acidity. When, as a result of subtotal gastrectomy, an acidity or acid values of 10 or below can be produced, there will be few if any gastrojejunal ulcers, and the end results will be good. It is not necessary in our experience after subtotal gastrectomy to do jejunostomies or to introduce indwelling Levine tubes into the stomach, since these patients can be fed almost immediately after operation and, if adequate stomas are left, drain quite promptly and are not, in the majority of cases, bothered by postoperative vomiting.

another ulcer in spite of the high subtotal gastrectomy unless he takes every precaution in the way of change in his eating and living habits to prevent its recurrence.

JEJUNAL ULCER

Jejunal ulcer, sometimes called gastrojejunal ulcer, stoma ulcer or marginal ulcer, probably occurs in a much higher percentage of patients on whom gastroenterostomies for duodenal ulcer have been done than has been assumed to be true in the years gone by. What the exact incidence is, we cannot be absolutely sure, but it can safely be said to be over 15 per cent. In addition, as shown in our figures concerning the time gastrojejunal ulcer has

occurred after gastrectomy, it is not safe to assume that if a patient who has had a gastroenterostomy for duodenal ulcer goes three or four years, he is safe from the occurrence of this lesion. In patients coming here for surgery who have had gastro-

troenterostomy has been done that later closes, the closure is the result of the cicatrix that follows the spontaneous healing of a gastrojejunal ulcer. We have several times seen such scars about the marginal stoma that brought about closure and must have been due to a healing of a previously existing gastrojejunal ulcer.

We believe that there is but one indication for immediate surgery in gastrojejunal ulcer, and that is when, as shown in Figure 14, it can be demon-

FIGURE 13 Roentgenogram of a Patient Who Developed a Gastrojejunal Ulcer after a Subtotal Gastrectomy

The first operation, done elsewhere, was inadequate, and a second subtotal gastrectomy had to be done. Compare the extent of this resection with the resection in Figure 12 to demonstrate the radicalness of the procedure employed.

FIGURE 14 Roentgenogram Showing a Jejunal Ulcer Adherent to the Transverse Colon

This ulcer was ready to produce a gastrojejuno-colic fistula but, as proved by operation, it had not perforated.

enterostomies for duodenal ulcers gastrojejunal ulcers have occurred as late as twenty-seven years after operation.

Jejunal ulcer is known to be an intractable type of ulcer, and used to be thought to be so intractable that surgery should be employed in every case. We have now dealt with a sufficient number of these cases so that we know that some of them can be handled medically and that, under such management, the ulcers will heal. In fact, it is our opinion that some jejunal ulcers occasionally heal spontaneously without accurate medical management. It is in all probability true that when a good gas-

strated that the jejunal ulcer is adherent to the transverse colon and in the process of perforating into the colon to form a gastrojejuno-colic fistula.

In 87 consecutive patients who were operated on for gastrojejunal ulcer, the operation consisting of a high subtotal gastrectomy together with resection of that portion of the jejunum in which the stoma and the stomal ulcer existed, the mortality rate was but 23 per cent, demonstrating again that this lesion, although one of a complicated character, has even a lower mortality rate than that of duodenal

ulcer, again because of the fact that subtotal gastrectomy in duodenal ulcer, as already stated, is so often complicated by the fact that the ulcer is adherent to the head of the pancreas and to the common bile duct

GASTROJEJUNOCOLIC FISTULA

Gastrojejunocolic fistula is by all means the most serious lesion with which one deals in gastric surgery. It is a perforation into the transverse colon of a jejunal ulcer that has become adherent to the transverse colon, producing a fistulous tract varying in size from one that will barely admit a straw to an aperture, as shown in Figure 15, the size of a ten-cent piece

When large gastrojejunocolic fistulas occur, they result in a most undesirable physiologic state. They produce a condition that is comparable with pel-

FIGURE 15 Specimen Removed at the Second-Stage Operation for Gastrojejunocolic Fistula

The operation consists of partial colectomy, partial removal of the jejunum and subtotal gastrectomy. The gastrojejunocolic fistula is indicated by the arrow. Note its size and the amount of food that can be lost through it into the transverse colon

lagra and a weight loss that is often startling. This is due to the fact that the constant escape of feces into the stomach discourages the desire for food and the constant escape of gastric contents into the transverse colon results in a pellagra-like state because it does not permit a good fraction of the food ingested to pass through the small intestine, where it can be absorbed for proper nourishment

We have been through the employment of all types of procedures in an endeavor to handle patients with gastrojejunocolic fistulas successfully, and it was not until I devised the plan of cutting off the ileum at the ileocecal valve, turning the distal end in, and anastomosing the proximal end to the descending colon beyond the gastroenterostomy and

the fistula, with later subtotal gastrectomy and removal of the involved colon and jejunum, that we began to manage these cases successfully (Fig 16)

I devised this plan of procedure with the idea that I could so advance that portion of the fecal stream in the small intestine beyond the gastroenterostomy that less of the colonic contents would pass back into the stomach, that it would establish the fecal stream beyond the gastroenterostomy so that at

FIGURE 16

This illustration shows the completed procedure for handling subtotal gastrojejunocolic fistula. Note the anastomosis of the ileum to the descending colon, which is the first stage of the operation. At the end of three months these patients return, at which time the ascending colon, transverse colon and the section of the jejunum in which the ulcer and fistula exist are removed in one piece, and a subtotal gastrectomy is performed. This illustration shows the status of the gastrointestinal tract when both stages of the operation are completed (reproduced from Marshall¹⁵ by permission of the publisher)

the second stage of the operation when the subtotal gastrectomy together with the removal of the involved colon was undertaken, the anastomosis between the descending colon and the terminal ileum would already have been established and functioning. This operation has been successfully applied in 20 cases. In 2 of these the anastomosis of the ileum to the descending colon, a procedure that diverts the fecal stream from the ascending and transverse colon, has resulted in spontaneous closure of the fistulous tract after the first stage of the

operation and has resulted in there being no necessity for doing the radical second stage of the procedure to remove the fistula and the jejunal ulcer, together with the transverse colon

It has been our experience in the remaining 18 cases in which the second stage of the operation has been done (Fig 16), that if these patients are sent home for two to three months following the anastomosis of the ileum to the descending colon, thus advancing the fecal stream beyond the fistula, they will return at the end of this time in much improved general condition, with a gain in weight and with such improvement that the radical procedure of the second stage can be employed with a reasonable prospect of survival

When one at first views this procedure, it appears to be so extensive as to unduly impress one with its magnitude. As we have done more and more of these operations, we have become aware that, with the fecal stream already established beyond the fistulous tract and with the patient in improved condition, it is possible, with reasonable ease, to cut the transverse colon off between the two rows of clips put in by the von Petz sewing machine beyond the fistula, just proximal to the splenic flexure, to turn the two ends in safety and to mobilize and devascularize the ascending colon and transverse colon, at which time the exposure becomes so adequate and complete that the operation, which consists of removing four fifths of the stomach, the involved segment of the jejunum and the ascending and transverse colon with the fistula into the splenic flexure, can be done more easily than the operation of subtotal gastrectomy and the removal of the jejunum alone in jejunal ulcer

This is an operative plan for this serious lesion that offers the following advantages: the prospect that in a small percentage of cases following the implantation of the ileum into the descending colon, the fistula will heal spontaneously and the second stage of the operation will be unnecessary, and the fact that the marginal ulcer, together with the fistulous tract into the colon and that portion of the stomach to be removed in the subtotal gastrectomy, can be removed in one block without spilling colonic contents and without the dangers of colon-bacillus contamination that go with any operative procedure

in which a fistula into the colon has to be opened and the fistulous tract into the colon closed

This procedure in our hands has made it possible to deal with these patients with gastrojejuncolic fistula, who are so often emaciated and in extremely poor condition, more satisfactorily than with any other type of procedure that has been proposed

In the last ten years, this operation has been performed in 22 cases, with 2 deaths, a mortality of 9 per cent

* * *

I have purposely avoided any detailed discussion of technical surgical procedures in this oration before this general audience

The mortality rates in the four types of peptic ulcer — gastric, duodenal, jejunal and gastrojejuncolic fistulas — are given, as well as those of radical operations and of palliative operations for malignant lesions of the stomach

The type of lesions in which total gastrectomy has been applied in 89 cases and the total mortality in this group, together with the change between the mortality rate in the first 46 cases and that in the last 43 cases, are included

Some of the measures by which the now unsatisfactory end results of surgery for gastric cancer can be improved are stated

The mortality rate with transthoracic resection of the lower end of the esophagus and cardiac end of the stomach is reported again in two groups to indicate the improvement, as in total gastrectomy, that has come with added experience and improved selection

Hiatus hernia, peptic ulcer of the esophagus and leiomyoma of the stomach are discussed, as are gastric ulcer, duodenal ulcer, jejunal ulcer and gastrojejuncolic fistula, and experiences and mortality rates in handling this group of cases are given

PRESIDENTIAL ADDRESS*

MOTIVATIONS AND OPPORTUNITIES

JAMES RAGLAN MILLER, M D †

HARTFORD, CONNECTICUT

THERE are two kinds of motivation that incite men to activity — those that push and those that pull. Hunger, thirst, cold, want and fear are motivations of the “pusher” type. These are sufficient on occasion to furnish a certain amount of activity, even in the most indolent. The classic example of this type of motivation is the burr strategically placed near the rear end of the donkey. By reputation the burr is an effective measure in these circumstances to activate this obstinate animal.

On occasion the same obstinate donkey can be led along the path of progress by a “puller” type of motivation. A bit of hay located at the front end makes use of his weakness for appetizing fodder. This type of motivation is subtler than the first. It will not work if the animal is already fed or if the quality of fodder is poor, and it seems sometimes that the pure cussedness of the beast resists all stimulation, whether from the front or from the rear.

Physicians prefer to think that they are motivated by altruistic considerations of the puller type. Analogies like ripe fruit are good only for a brief period of ripeness, and although I should not have you think that I believe that medical organizations act like donkeys, I recall the elder statesman who in commenting on an approbrious epithet that one of his colleagues had used in reference to another said, “I should not classify our colleague by that term, but since it has been used I understand perfectly what is meant.” It will do us no harm occasionally to see ourselves as others see us, even though the exercise does not increase our self-complacency. The public has a high regard for the individual physician but is critical of us as a social group. To put it in the vernacular, they think that we have a “swell racket.” This criticism has, in a measure, crystallized in a series of socialistic provisions for medical care by government that you all recognize as centered in the Wagner-Murray-Dingell Bill. It appears to me that this threatening legislation, much as we dislike it, has nevertheless served as an effective pusher type of motivation, operating on organized medicine to produce not only resistance to the unsound legislation itself but to strengthen liberal movements within medicine that promise much for the good of society.

Meetings of the New England Surgical Society are usually devoted to the discussion of clinical

*Read at the annual meeting of the New England Surgical Society
Boston February 6 1946

†Visiting obstetrician and gynecologist Hartford Hospital

topics. Nevertheless, more than one president has seen fit to discuss some of the organizational problems that are encountered in the hospital, and it is my observation that the members have welcomed such a discussion. I too shall indulge in this exercise.

In his presidential address before this society in Hartford in 1932, Dr Frank H. Lahey told us that if physicians do not take more interest in the management of the hospitals in which they work, they will gradually find themselves working not in but for those hospitals. This same advice holds good on the state and national level today. If physicians are to retain a dominant influence in the provision of medical care, they must raise their eyes more than occasionally from the sickbed or the operating table and help to solve the intricate problems of programming that are before us.

You are all familiar with the Hill-Burton Bill, which at present seems destined in some form to pass the present Congress. This bill calls for the study of the need for hospitals and health centers and provides for some construction where needed. It is important for us to remember that this bill as modified has the endorsement of the American Medical Association. When it goes into effect, we shall be compelled to think constructively in terms somewhat larger than has been our habit in the past, when our concern has been mostly with the management of our own individual hospitals. We shall have to plan for participation in a much more complex system of large and small hospitals, so integrated that skills and facilities can be made more generally available to the public.

In New England, as much as anywhere in the country, it has been a characteristic of the organization of medicine that it is decentralized and highly individualistic. I should be the last to wish to lose the advantages of this habit. We should, however, recognize some of its disadvantages and limitations. When physicians act as members of a group, they do so on three levels. The most significant group for the New England doctor is his hospital staff. Here the problems are almost exclusively clinical and have to do with the care of his patients. Next in order of significance in his mind is the local medical society or academy of medicine. He will attend its meetings if there is a good clinical program, otherwise not. Last of all comes his county or district association. This is the backbone of the guild organization, but here also clinical programs must be supplied to get a good attendance. Special regional

operation and has resulted in there being no necessity for doing the radical second stage of the procedure to remove the fistula and the jejunal ulcer, together with the transverse colon

It has been our experience in the remaining 18 cases in which the second stage of the operation has been done (Fig 16), that if these patients are sent home for two to three months following the anastomosis of the ileum to the descending colon, thus advancing the fecal stream beyond the fistula, they will return at the end of this time in much improved general condition, with a gain in weight and with such improvement that the radical procedure of the second stage can be employed with a reasonable prospect of survival

When one at first views this procedure, it appears to be so extensive as to unduly impress one with its magnitude. As we have done more and more of these operations, we have become aware that, with the fecal stream already established beyond the fistulous tract and with the patient in improved condition, it is possible, with reasonable ease, to cut the transverse colon off between the two rows of clips put in by the von Petz sewing machine beyond the fistula, just proximal to the splenic flexure, to turn the two ends in safety and to mobilize and devascularize the ascending colon and transverse colon, at which time the exposure becomes so adequate and complete that the operation, which consists of removing four fifths of the stomach, the involved segment of the jejunum and the ascending and transverse colon with the fistula into the splenic flexure, can be done more easily than the operation of subtotal gastrectomy and the removal of the jejunum alone in jejunal ulcer

This is an operative plan for this serious lesion that offers the following advantages: the prospect that in a small percentage of cases following the implantation of the ileum into the descending colon, the fistula will heal spontaneously and the second stage of the operation will be unnecessary, and the fact that the marginal ulcer, together with the fistulous tract into the colon and that portion of the stomach to be removed in the subtotal gastrectomy, can be removed in one block without spilling colonic contents and without the dangers of colon-bacillus contamination that go with any operative procedure

in which a fistula into the colon has to be opened and the fistulous tract into the colon closed

This procedure in our hands has made it possible to deal with these patients with gastrojejunal fistula, who are so often emaciated and in extremely poor condition, more satisfactorily than with any other type of procedure that has been proposed

In the last ten years, this operation has been performed in 22 cases, with 2 deaths, a mortality of 9 per cent

ever, the financial condition of most of the states is extremely secure, and the state treasury is the natural source of help that should be developed in the future.

Now that the G. I. Bill of Rights is lifting part of the financial burden, I believe that it might be possible to obtain subsidies from state legislatures for a teaching program in hospitals possessing some of the features that I have outlined.

In Connecticut there has been much talk of establishing a medical department of the University of Connecticut. I do not know how far this movement will go, but it is stimulating to talk about it. If it were possible to buy a medical school and install it as one would an air-conditioning system in one's home, it might be that the cost would run to something between \$15,000,000 and \$40,000,000, including endowment. The cost, as you well know, would depend a good deal on the extent of the program and on the number of "ivory towers" that are built in. This, of course, would be the undergraduate medical school of the customary type, and I think that most legislatures would not be responsive to a program of such magnitude.

Although many persons, including myself, believe that an undergraduate medical school should be developed by the State of Connecticut, the need of the day, as I see it, is not so much for undergraduate medical education as it is for continued instruction after the doctor comes out of medical school. Postgraduate instruction should become a permanent part of the system of medical education, and its development should take place whether or not there is an accompanying undergraduate curriculum. Each should complement the other. No vast building program is necessary for such a program, for we already have the buildings, which are our own hospitals. All that is needed is a faculty, a large part of which is to be found in the hospital staffs. I am merely suggesting that these facilities be brought together in a more formal manner, placing on the governing board adequate representation of hospitals, medical societies, the university and the legislature. Medical teaching should be at three levels, those concerning the intern, the resident and the staff—which of course includes the courtesy staff. The university could furnish the dean's office and the academic

mechanisms for the program, and through it would come adequate compensation for those who carry on the burden of teaching. From the point of view of the intern and resident, the university could assure each one that he would get a training of high quality in his postgraduate years.

Tax-supported hospital systems have too often been veritable badlands of medicine. Exceptions to this rule are chiefly notable because they are exceptions. Now, badlands and deserts can be made to bloom by irrigation, and for the badlands of medicine the irrigation must be from the springs of medical education. This is the ray of hope that illuminates the future of the Veterans Administration under the plans of Generals Bradley and Hawley and our own General Cutler. Vast museums of living examples of various diseases in our state and municipal institutions are going to waste unused by our system of medical education. Is it not possible that this source of material can in some measure make up for the shrinkage of our ward services that has taken place under the influence of prepaid medical and hospital plans?

* * *

In these few remarks I have made two suggestions that have admittedly been very incompletely developed. Each may stand alone, although together they are complementary.

First, organized groups of hospital staff officers might be developed into sections in the state medical societies. Second, postgraduate medical education is needed on three levels, those of the intern, the resident physician and the community physician. This could be developed at moderate expense by a combined effort of the medical societies, hospitals, a state university and the state legislature. †

If imagination is needed to recognize the opportunity that lies before us, aggressive and courageous leadership will be necessary to develop it. Great generosity and largeness of spirit will be necessary to adjust many local and personal obstacles, but these are not times when medicine can afford to let the ambitions and prejudices of little men obstruct the proper development of all our resources to give full medical service to the public.

179 Allyn Street

and national societies also absorb the interest of many physicians, especially those who have the greatest capacity for leadership

Just at this point it appears to me there is an opportunity for us to develop a program, as in fact we must do under the Hill-Burton Bill, by enlisting the interest of many whose talents for organization have hitherto been developed only within their own hospitals. I believe that it should be possible in some way to bring together those who are concerned with matters of staff organization in hospitals and to make them realize their dependence on the welfare of the whole guild of medicine. Policies of staff relations to boards of directors, to community physicians, to insurance carriers and to plans for medical care and kindred topics would be eagerly discussed.

It should be possible for each state medical society at its annual meeting to arrange for a conference of hospital staff officers. In such gatherings discussion should be limited to matters of an organizational nature. I am familiar, of course, with the work that the American College of Surgeons has done along this line for many years. Dr. Walter G. Phippen and many another member of the Society have been interested, as you know, but so far none of us have been able to capitalize for the benefit of organized medicine the tremendous resources of ability that develop in hospital staffs. State medical societies could do their members a great service if they would recognize how deep is the interest of many of their members in these problems and how great would be the support for a section on hospital staff affairs if developed exactly as other specialties have been organized. Here also would be a forum for the discussion of the problem of the ordinary practicing physician who has no staff connections. Here too could be discussed many problems that arise in connection with prepaid medical and hospital plans.

Such conferences as I have suggested would hasten the day when responsible staff members would sit at regular intervals throughout the year with the board of trustees of the hospital. Whether or not they have a vote is immaterial. Some hospitals have already established such intimate relations, although there are too many the staff and trustees of which view each other with a certain amount of suspicion.

The motto of such staff representatives might well be a paraphrase of the lines of Richard Lovelace: "Stone walls do not a prison make, nor marble halls a hospital." I do not have to labor this thought before the New England Surgical Society, but it is one that should be mentioned again and again in the councils of hospital management. Frankness, honesty, initiative, originality, clear thinking and seriousness of purpose are not items that appear prominently on the balance sheets of any organization, but they are ingredients failing which no institution can long survive, and those who budget "for hospital care must make due provision for their cultivation."

I believe that the time is ripe for us to make a bold experiment in medical education, one that may never have been contemplated in just the terms that I wish to propose. I am thinking particularly of our situation in the New England states, although some western states have developed certain of its features. Except in teaching hospitals and in a very few of the nonteaching centers, we must admit that the intern does not get a good postgraduate education. At least it is not nearly so good as we know how to give. He feels that he is merely an extra pair of hands with legs and fountain pen attached. Most of the nonteaching internships would not be selected by a physician for his own son except perhaps in his own hospital, with the hope of thus assuring him a speedier and easier entrance into local medical practice.

In the report of the subcommittee on intern curriculum prepared for the Connecticut Postwar Planning Board's Committee on Medical Care and Health, the following statement was made:

The studies initiated by the committee were for the purpose of determining how intern service in many Connecticut hospitals could be improved and made more attractive, to the end that the recruitment of house staffs for Connecticut hospitals might be more adequate in the future and thereby increase the usefulness of the hospitals and attract well trained physicians to the state for intern training, with the possibility that they might permanently locate in practice here to make up natural losses.

Among other things the committee recommended the employment of full-time or part-time medical personnel to cover the fields of pathology, radiology, anesthesiology and psychiatry for all hospitals of more than 100 beds. For those of more than 200 beds it was recommended also that a full-time physician be employed as a teacher to co-ordinate the hospital's educational program for interns, residents and staff members.

Such a program comes face to face with practical considerations of financing. Only a small part of it may be added to the patient's per diem charges, although he benefits from it directly as well as indirectly. If a satisfactory teaching program is developed, even though every expedient be employed to activate the voluntary services of the unsalaried staff, the costs will be more than can be borne without subsidy from private or public sources.

Medical schools that in the past have kept income and expense budgets on speaking terms with each other are greatly concerned with diminishing returns from private sources and are exploring the possibilities of government support. It is well known that the springs of private philanthropy are gradually drying up. Federal subsidies have not appealed to the New England mind because of the objectionable federal control that goes along with such subsidies, and if we are realists we should look at the huge national debt and become cautious when we think of federal subsidies in relation to long-range planning. In contrast to the federal treasury, how-

blood picture continued to improve, so that on February 15 it was believed that a transfusion would not be necessary, and only intravenous fluid was given. On that day the hematocrit fell from 32 to 29 per cent and the red-cell count from 3,240,000 to 2,350,000. For this reason blood transfusions were again started the following day, 500 cc being given daily for 3 successive days. For the next 2 days, February 19 and 20, the blood levels maintained themselves, but on February 21 the hematocrit fell from the 32 per cent of the previous day to 29 per cent, with a corresponding drop of the hemoglobin and red-cell count. There was no rise of the

The subsequent course was one of gradual improvement in both the clinical and laboratory findings. No further transfusions were required. The patient was given large doses of oral and parenteral vitamins, ferrous sulfate and a high-vitamin diet. The red cells gradually increased in number, and there was a concomitant decline in the titer of cold agglutinins in the serum. The pneumonic process resolved slowly, but by March 28 the lungs were entirely clear on both physical and roentgenographic examination. Despite the complete clearing of the lungs, the patient continued to have low-grade fever, with a temperature between 99 and 100°F.

FIGURE 1 Clinical Course and Essential Laboratory Findings

spleen index. Accompanying this fall in the levels of the red-cell components the patient stated that he felt weaker. He was sweating considerably, the pulse rose from 100 to 120, and dyspnea appeared prominent. The blood pressure was maintained. In the fear that another hemolytic crisis was imminent, 500 cc. of whole blood was again given, following which the pulse and respiratory rate diminished, and subsequently the patient was better. At that time the titer of cold agglutinins in the serum was 1:2048, this probably being the first correct titer obtained. On February 22 for the first time the lower border of the liver could be palpated as a rounded, nontender, firm edge 3.5 cm. below the right costal margin in the midclavicular line. The organ had been enlarged to percussion since February 17, and a definite sense of resistance in the right upper quadrant of the abdomen had been felt. The liver remained this size for 4 days and then began to recede gradually, so that on March 2 it could no longer be palpated. The spleen was not palpable throughout the course of the illness.

in the afternoon and evening. This continued on a diminishing level until he was essentially afebrile after April 21. At discharge on May 29, the patient was asymptomatic and the laboratory findings were normal. The cold agglutinin titer was 1:4. The patient was returned to full duty. This patient developed an acute hemolytic anemia with the presence of a high titer of cold agglutinins (autohemagglutinins), and the decrease of the anemia roughly followed a parallel course with the decrease of the cold agglutinins in the serum. None of the other factors that may cause such a hemolytic crisis were present. The Donath-Landsteiner phenomenon was absent, there was no acid-hemolysin, and no sickling tendency was present. There was a slightly increased fragility of the red cells to hypotonic saline solution.

ACUTE HEMOLYTIC ANEMIA IN PRIMARY ATYPICAL PNEUMONIA ASSOCIATED WITH HIGH TITER OF COLD AGGLUTININS*

Report of a Case

MAJOR HAROLD S GINSBERG, M C, A U S

SEVERAL observers¹⁻⁴ have reported cases of acute anemia occurring in patients with primary atypical pneumonia who have developed high titers of cold agglutinins (autohemagglutinins). Since all these patients, with 2 possible exceptions, had been given one of the sulfonamide drugs, an additional etiologic factor was present that these authors thought might have been the primary or a contributory cause of the hemolytic crisis.[†] In the case reported below, no sulfonamide drug or any other medicinal agent was used that could have been an etiologic factor responsible for the causation of the acute hemolytic anemia.

CASE REPORT

The patient, a 34-year-old soldier, was admitted to a United States Army general hospital on February 2, 1944 with a 24-hour history of increasing malaise, frontal headache, sore throat, cough slightly productive of yellow sputum, fever and chilliness, slight shortness of breath on moving about or talking and generalized muscle aches and pains. The past history was negative except for an episode of nasopharyngitis 3 weeks before the present admission.

On physical examination the patient was slightly uncomfortable and was coughing frequently. The cough was productive only of small amounts of frothy white-yellow sputum. There was slight tachypnea but no orthopnea and no dyspnea except with effort, and no cyanosis. The temperature was 102°F, the pulse 86, the respirations 19, and the blood pressure 122/82. The skin was extremely hot, dry and elastic, the color was good. Examination of the lungs revealed no abnormalities. The remainder of the physical examination was negative. The hemoglobin was 85 per cent (Tallqvist) and the white-cell count 9250, with 75 per cent neutrophils, 22 per cent of which were stab forms. Urinalysis and a blood Kahn test were negative.

The morning after admission the temperature was 103°F (Fig 1), the respiratory distress on effort had increased somewhat, and the cough had become slightly more productive. Scattered, fine, moist, crepitant rales could be heard over the left upper lobe anteriorly. A portable roentgenogram of the chest revealed a patchy density of the left upper lobe and the upper portion of the left lower lobe. The sputum smear and culture revealed no pathogens, and blood culture showed no growth. There soon developed slight dullness over the entire left lung, and numerous rales were heard throughout it. The white-cell count began to climb slowly, but owing to the fact that the sputum never assumed the characteristics of a bacterial pneumonia by gross examination, direct smear or culture, sulfonamide therapy was not begun. The titer of cold agglutinins in the peripheral blood on February 5 was +++++ in a dilution of 1:4.

Beginning on February 7, the patient began to feel much better, and the temperature appeared to be beginning a slow decline. The dyspnea and cough remained as prominent symptoms, and examination of the lungs showed no change. On February 9, the temperature for the first time fell to normal throughout the morning, and the patient felt greatly

improved. By the following morning, however, a new chapter proved to be commencing. At that time the patient stated that he felt much weaker. Dyspnea still appeared rather prominent, and he was slightly cyanotic, but the pulmonary signs were unchanged. That afternoon slight icterus was first noted, otherwise physical examination revealed no change. The liver was not palpable, and the patient seemed to be in no distress. On the following morning the hemoglobin was 60 per cent (Tallqvist) and the white-cell count was 44,350, with 93 per cent neutrophils, 37 per cent of which were immature forms. The urine was reddish-brown, negative to the benzidine test and positive for bile and urobilinogen and gave a +++ test for albumin. The sediment showed 1 or 2 white cells per high-power field.

Within a few hours the hemoglobin was 45 per cent (Tallqvist), the red-cell count 1,360,000, the hematocrit 19 per cent, and the white-cell count 40,850, with 99 per cent neutrophils, 36 per cent of which were immature forms. Thus, the Wright-stain preparation of the blood smear revealed a typical leukemoid picture. Two nucleated red cells per 100 white cells were seen, and spherocytosis and polychromatophilia were noted. The red-cell count could be done only by first warming the diluting fluid. The direct platelet count was 451,520. The bleeding time was 6 minutes, and the clotting time 10 minutes, the clot retractility was good. The icteric index was 52. Urine urobilinogen was present in a titer of over 1:1000. There was bile in the urine but no blood. Bile was also present in the stools. Hemoglobinemia was present. Gross agglutination of the blood at room temperature was observed, even in high dilutions, this disappeared by warming above 37.5°C. Blood for determination of the titer of cold agglutinins was drawn, but could not be done for several days owing to lack of an adequate icebox. The Donath-Landsteiner phenomenon was negative. No sickling was observed in a sickle-cell preparation. No acid hemolysis was present in the serum. Blood allowed to clot and retract slowly at room temperature hemolyzed slightly.

Between the first laboratory tests and the completion of the second set of determinations the condition of the patient changed rapidly from that of a moderately uncomfortable patient to that of one who was so seriously ill as to be practically moribund. The blood pressure gradually fell from 124/70 to 100/44.

The typing of the patient's cells was not possible at incubator temperature, as well as at room temperature, owing to the high degree of adsorption of the agglutinin by the red cells, similarly, cross matching could not be performed. It was decided to use the specific type of blood, Type B, as determined by the patient's Army identification tags, rather than to use an uncross-matched blood of a universal donor.

Following alkalization the patient was given 500 cc of blood, which was kept warm throughout the transfusion. The blood was given over a period of 40 minutes, and no reaction occurred. Early the next morning 1000 cc of Type B blood was given, following which the patient appeared and felt much better. Blood taken for laboratory studies 1½ hours after the second transfusion revealed a marked improvement over the preceding day. An extremely slight increase in the fragility of the red cells to hypotonic saline solution was found. Agglutination of the blood at room temperature still occurred. The same afternoon the dyspnea seemed to be tiring the patient so much that oxygen by means of a mask was begun, from which the patient received considerable relief, both objectively and subjectively.

On February 14, rales were first heard over the right lower lobe and right middle lobe, they were fine, moist and crepitant and were scattered throughout these lobes. An x-ray film of the chest taken the following day showed coarse mottling throughout the right lung, the process on the left had cleared somewhat, but there were still fairly coarse, mottled densities in the upper third and lower half of this lung. The

*From the Seventh General Hospital.

†Since this paper was prepared and submitted for approval by the office of the Surgeon General, Finland et al.,⁵ in their series of papers on the laboratory and clinical features of cold isohemagglutinins, reported 11 cases of anemia of varying severity occurring in cases of primary atypical pneumonia having significant titers of cold agglutinins. In 4 of these, a marked drop of hemoglobin from 40 to 70 per cent occurring over a period of three days or less was noted, in 1 case no sulfonamide was given before the onset of the hemolytic anemia. Four of the patients in the entire group had received no sulfonamides before the development of the anemia.

SUMMARY

A case of acute hemolytic anemia developing during the course of a severe primary atypical pneumonia that developed a high titer of cold agglutinins (autohemagglutinins) is presented. This patient received no sulfonamide therapy or treatment with any other drug that might have been the cause of the acute hemolytic process. Recovery occurred following repeated transfusions.

It is important to recognize that the pneumonias of the primary atypical type so prevalent for the last several years may develop a high titer of cold agglutinins that in themselves may be the cause of an acute hemolytic anemia as a serious complication.

MEDICAL PROGRESS

HEMATOLOGY

WILLIAM DAMESHEK, M.D.*

BOSTON

THE SPLEEN

IN its normal state, the spleen is a relatively small organ weighing 50 to 100 gm and containing a variable amount of blood. Its function as a reservoir was thoroughly studied twenty-one years ago by Barcroft et al.¹ Removal of the normal spleen is followed by a number of interesting blood changes² — a tendency toward an increase in the red-cell count, the development of thin red cells (target cells) with increased hypotonic resistance, the development of Howell-Jolly bodies (nuclear remains) in the red cells and increases in the white-cell and platelet counts. These changes indicate a definite relation between the spleen and the blood-forming organs, notably the bone marrow, perhaps mediated by splenic hormones. The presence of red cells with nuclear fragments in the blood may indicate a splenic influence on denucleation of the red cell. Leukocytosis and thrombocytosis may be indicative of a spleen-granulocyte and a spleen-megakaryocyte relation. The development of thin red cells after splenectomy probably indicates that the mature red cells become thicker in their numerous but slow passages through the splenic sinusoids.

Although it is reasonable to assume that the spleen makes red cells thicker and thus prepares them for eventual breakdown so that they become more and more spherocytic, it is not known that the spleen actually destroys red cells. The old saying that the spleen is the graveyard of the red cells may require modification. Singer and Weisz,³ by studying the bile excretion of normal and splenectomized dogs after phenylhydrazine hemolysis,

demonstrated that there was no decrease in the output of bile pigment in the splenectomized animals. Thus, in dogs at least, and under the conditions of these experiments, it seems that the spleen has little if any influence on blood destruction. These results, so contrary to the long accepted opinions on this subject, must be confirmed in other animals and by different experimental methods before they can become completely accepted. The life span of the erythrocyte, as determined in these experiments, was approximately one hundred and ten days, in line with the more recent investigations on this point. Thus, it appears that less than 1 per cent of the red cells are destroyed daily. The actual process of red-cell destruction in the normal animal is but little known and may be simply a matter of increased spherocytosis and gradual wearing down (fragmentation).

The Spleen as an Endocrine Organ

The spleen is not ordinarily included among the organs of internal secretion. Nevertheless, more and more evidence — to be sure, largely of the indirect type — is accumulating that the spleen produces hormones that enter the blood stream and have effects on remote organs, notably the bone marrow. The recent series of observations of White and Dougherty⁴ indicate a hormonal relation between the adrenal cortex and lymphoid tissue. Ungar⁵ recently isolated from the normal spleens of guinea pigs a crystalline substance that he called "splenin" and that had the property of causing a reduction in the bleeding time, an increase in the capillary resistance and an inhibition in the release of histamine from blood cells. It was found that the spleen participated in the endocrine response

*Professor of clinical medicine, Tufts College Medical School, hematology, Joseph H. Pratt Diagnostic Hospital.

Owing to lack of facilities, it was impossible to perform several laboratory tests that might have been illuminating both during the acute illness and during the convalescence. The lack of them does not, however, detract from the important features in this case.

It was impossible to do the usual hepatic-function tests, so that the true status of the liver function during the acute illness, as well as during convalescence, could not be determined. There is, however, no clinical reason to believe that there was any decreased function at the time of discharge. The plasma proteins, prothrombin time and icteric index at discharge were normal, the hippuric acid excretion was slightly diminished (2.83 gm, oral test).

The cold agglutinins react as do other agglutinins in that they can be adsorbed by red cells at 0 to 5°C and in some cases even at room temperature, as was true in this case. The venous blood removed from February 12 and 14 was by an oversight allowed to separate slowly at room temperature, and without separation of the serum from the clot was placed in the icebox, which was at a temperature of about 10°C, until February 18, when the icebox was for the first time well enough regulated to maintain a temperature between 0 and 5°C, at which time these two serums as well as one drawn on February 18 were tested. The cold agglutinin titer of the later serum, which was separated immediately, the test being performed the same day, was 1:2048. Keeping in mind the fact that bloods drawn on February 12 and 14 showed autoagglutination at room temperature, we have every reason to believe that the actual titer in each serum was much higher than the test indicates.

Owing to the nonavailability of potassium dichromate at the time of the acute illness, it was impossible to make accurate standards for the determination of the icteric index. This accounts for the somewhat irregular curve of these determinations.

DISCUSSION

The development of high titers of cold agglutinins (autohemagglutinins) was first reported in a large series of patients with primary atypical pneumonia of unknown etiology by Peterson, Ham and Finland.¹ This observation was confirmed by Horstmann and Tatlock² and shortly afterward by Turner, Nisewitz, Jackson and Berney.³

Peterson et al.¹ first noted the presence of high titers of cold agglutinins in primary atypical pneumonia in 2 cases of the prevalent type that developed an acute hemolytic anemia during the course of the pneumonia. The presence of the reversible autohemagglutinin (cold agglutinin) was discovered when the difficulties of blood grouping and cross matching were met. Shortly afterward a similar case was seen by these writers. In 2 of the above cases sulfonamides had been used,⁷ so that the

causative agent of the hemolytic crises was of necessity in doubt. The third patient died before adequate laboratory data could be obtained.

Horstmann and Tatlock² likewise reported 2 cases of primary atypical pneumonia that had a titer of cold agglutinins and developed an acute hemolytic anemia. In 1 of these cases, which was fatal, they reported that the patient had had sulfadiazine nine days before the development of anemia, and stated that the part that the drug played in the anemia was unknown. It was not mentioned whether the second patient, who recovered, had received a sulfonamide drug.

Dameshek³ reported 2 cases of primary atypical pneumonia with autoagglutination of the red cells due to cold agglutinins, each of which developed an acute hemolytic anemia. These patients also had received sulfonamides, which the author believed was related to the mechanism of the hemolysis.

Stats and Wasserman,⁴ in their excellent review of cold hemagglutination, mention a case of acute hemolytic anemia with high titers of cold agglutinins occurring during the course of primary atypical pneumonia. The patient had received sulfonamide, and the authors state that the exact causal relation between the pneumonia, the cold hemagglutination, the sulfonamide and the acute hemolytic anemia was not clear. They are of the opinion, however, that because of the parallelism between the titer of the agglutinin and the hemolysis the two are associated pathogenically.

Antopol et al.⁵ described 2 cases of acute hemolytic anemia with autoagglutination following sulfonamide therapy, one of which was a pneumonia of questionable type treated with Neoprontosil.

The mechanism of the acute hemolytic anemia in these cases of primary atypical pneumonia with high titers of cold agglutinins is still not clear, but the presence of this phenomenon without sulfonamide therapy helps to clarify it somewhat. It can be stated that the hemolysis in such cases as the one reported here is not due to a combination of a high titer of cold agglutinins and injury of the red cells by sulfonamides, as Dameshek³ thought. Rather, the hemolysis may be due to agglutination of the red cells in the peripheral vessels, resulting in stasis, the hemolysis taking place as a result of trauma. Stats³ has caused hemolysis *in vitro* by mild trauma while using blood and fresh plasma with a high titer of cold agglutinins. The agglutinins themselves may injure the red-cell membrane and thus make them more susceptible to the factors of stasis and trauma.

The fact that many cases of primary atypical pneumonia with extremely high titers of cold agglutinins do not have hemolytic crises still remains a complete mystery.

SUMMARY

A case of acute hemolytic anemia developing during the course of a severe primary atypical pneumonia that developed a high titer of cold agglutinins (autohemagglutinins) is presented. This patient received no sulfonamide therapy or treatment with any other drug that might have been the cause of the acute hemolytic process. Recovery occurred following repeated transfusions.

It is important to recognize that the pneumonias of the primary atypical type so prevalent for the last several years may develop a high titer of cold agglutinins that in themselves may be the cause of an acute hemolytic anemia as a serious complication.

The actual process of red-cell destruction in the normal animal is but little known and may be simply a matter of increased spherocytosis and gradual wearing down (fragmentation).

The Spleen as an Endocrine Organ

The spleen is not ordinarily included among the organs of internal secretion. Nevertheless, more and more evidence — to be sure, largely of the indirect type — is accumulating that the spleen produces hormones that enter the blood stream and have effects on remote organs, notably the bone marrow. The recent series of observations of White and Dougherty⁴ indicate a hormonal relation between the adrenal cortex and lymphoid tissue. Ungar⁵ recently isolated from the normal spleens of guinea pigs a crystalline substance that he called "splenin" and that had the property of causing a reduction in the bleeding time, an increase in the capillary resistance and an inhibition in the release of histamine from blood cells. It was found that the spleen participated in the endocrine response

*Professor of clinical medicine, Tufts College Medical School; hematologist, Joseph H. Pratt Diagnostic Hospital.

Owing to lack of facilities, it was impossible to perform several laboratory tests that might have been illuminating both during the acute illness and during the convalescence. The lack of them does not, however, detract from the important features in this case.

It was impossible to do the usual hepatic-function tests, so that the true status of the liver function during the acute illness, as well as during convalescence, could not be determined. There is, however, no clinical reason to believe that there was any decreased function at the time of discharge. The plasma proteins, prothrombin time and icteric index at discharge were normal, the hippuric acid excretion was slightly diminished (2.83 gm, oral test).

The cold agglutinins react as do other agglutinins in that they can be adsorbed by red cells at 0 to 5°C and in some cases even at room temperature, as was true in this case. The venous blood removed from February 12 and 14 was by an oversight allowed to separate slowly at room temperature, and without separation of the serum from the clot was placed in the icebox, which was at a temperature of about 10°C, until February 18, when the icebox was for the first time well enough regulated to maintain a temperature between 0 and 5°C, at which time these two serums as well as one drawn on February 18 were tested. The cold agglutinin titer of the later serum, which was separated immediately, the test being performed the same day, was 1:2048. Keeping in mind the fact that bloods drawn on February 12 and 14 showed autoagglutination at room temperature, we have every reason to believe that the actual titer in each serum was much higher than the test indicates.

Owing to the nonavailability of potassium dichromate at the time of the acute illness, it was impossible to make accurate standards for the determination of the icteric index. This accounts for the somewhat irregular curve of these determinations.

DISCUSSION

The development of high titers of cold agglutinins (autohemagglutinins) was first reported in a large series of patients with primary atypical pneumonia of unknown etiology by Peterson, Ham and Finland.¹ This observation was confirmed by Horstmann and Tatlock² and shortly afterward by Turner, Nisnewitz, Jackson and Berney.³

Peterson et al.¹ first noted the presence of high titers of cold agglutinins in primary atypical pneumonia in 2 cases of the prevalent type that developed an acute hemolytic anemia during the course of the pneumonia. The presence of the reversible autohemagglutinin (cold agglutinin) was discovered when the difficulties of blood grouping and cross matching were met. Shortly afterward a similar case was seen by these writers. In 2 of the above cases sulfonamides had been used,⁷ so that the

causative agent of the hemolytic crises was of necessity in doubt. The third patient died before adequate laboratory data could be obtained.

Horstmann and Tatlock² likewise reported 2 cases of primary atypical pneumonia that had a titer of cold agglutinins and developed an acute hemolytic anemia. In 1 of these cases, which was fatal, they reported that the patient had had sulfadiazine nine days before the development of anemia, and stated that the part that the drug played in the anemia was unknown. It was not mentioned whether the second patient, who recovered, had received a sulfonamide drug.

Dameshek⁴ reported 2 cases of primary atypical pneumonia with autoagglutination of the red cells due to cold agglutinins, each of which developed an acute hemolytic anemia. These patients also had received sulfonamides, which the author believed was related to the mechanism of the hemolytic crises.

Stats and Wasserman,⁴ in their excellent review of cold hemagglutination, mention a case of acute hemolytic anemia with high titers of cold agglutinins occurring during the course of primary atypical pneumonia. The patient had received sulfonamide, and the authors state that the exact causal relation between the pneumonia, the cold hemagglutination, the sulfonamide and the acute hemolytic anemia was not clear. They are of the opinion, however, that because of the parallelism between the titer of the agglutinin and the hemolysis the two are associated pathogenically.

Antopol et al.⁵ described 2 cases of acute hemolytic anemia with autoagglutination following sulfonamide therapy, one of which was a pneumonia of questionable type treated with Neoprontosil.

The mechanism of the acute hemolytic anemia in these cases of primary atypical pneumonia with high titers of cold agglutinins is still not clear, but the presence of this phenomenon without sulfonamide therapy helps to clarify it somewhat. It can be stated that the hemolysis in such cases as the one reported here is not due to a combination of a high titer of cold agglutinins and injury of the red cells by sulfonamides, as Dameshek³ thought. Rather, the hemolysis may be due to agglutination of the red cells in the peripheral vessels, resulting in stasis, the hemolysis taking place as a result of trauma. Stats⁹ has caused hemolysis in vitro by mild trauma while using blood and fresh plasma with a high titer of cold agglutinins. The agglutinins themselves may injure the red-cell membrane and thus make them more susceptible to the factors of stasis and trauma.

The fact that many cases of primary atypical pneumonia with extremely high titers of cold agglutinins do not have hemolytic crises still remains a complete mystery.

quick return to normal or better than normal granulocyte levels. Splenic neutropenia may be completely idiopathic — that is, the cause of the splenomegaly may be quite obscure — or may be associated with the splenomegaly of certain cases of rheumatoid arthritis (Felty's syndrome), Boeck's sarcoid, Gaucher's disease, tuberculosis of the spleen, malaria and kala-azar. In any of these conditions, and in others with splenomegaly, the neutropenia may become so severe as to lead to recurrent bouts of infection and fever. Patients with this syndrome often go from clinic to clinic without a definite diagnosis, with their lives frequently in jeopardy on account of the frequent development of pyogenic infections. Splenectomy has been extremely effective in an increasing number of cases. Recent reports include those of Langston, White and Ashley,¹² Rogers and Hall¹³ and Salzer, Ransohoff and Blatt.¹⁴

Splenic pancytopenia or panhematopenia — the latter is a term recently used by Doan and Wright¹⁵ — includes cases of splenomegaly in which there is a simultaneous reduction in all the cellular elements of the blood. Many patients with splenic neutropenia have more or less marked thrombocytopenia or anemia or both. In these cases it is of great importance to recognize that the pancytopenia is not due to aplasia or hypoplasia of the marrow but is brought about by an inhibitory effect of the enlarged spleen on the bone marrow. Doan thinks that a phagocytic effect is responsible. Many of these cases go unrecognized for years because either the spleen is not felt or the pancytopenia suggests the presence of a hypocellular marrow. Sternal-marrow studies reveal hypercellularity of all the elements, with large numbers of nucleated red cells, granulocytes and megakaryocytes. If the diagnosis and interpretations of the marrow picture are correct, splenectomy is usually followed by a quick return of the blood picture to normal.

These views, although relatively new, are being rapidly bolstered by increasing numbers of clinical cases. Together with the other bits of evidence, chiefly drawn from pathologic material, they strongly indicate the presence of splenic hormones having at times deleterious effects on the maturation and delivery of cells from the bone marrow to the blood. There is need for more direct evidence bearing on these points.

Rupture of the Spleen

With enlargement of the spleen in certain infectious states, notably in malaria and infectious mononucleosis, spontaneous rupture may occur, causing the symptoms of hemorrhage, shock and an abdominal emergency. Russ and Gaynor¹⁶ report the case of a soldier who had had a single attack of vivax malaria overseas. Eleven months later, in this country, he developed a malarial chill that was accompanied by acute pain in the left shoulder, which radiated to and was localized in the left upper

quadrant of the abdomen. Operation revealed a ruptured spleen and an abdomen filled with both fresh and old blood. Splenectomy was followed by recovery, but nine days postoperatively another chill occurred and *Plasmodium vivax* was recovered. Another case, also in a returned soldier, is reported by Kellner, Hochstein and Tillman.¹⁷ In this case, shock quickly developed and the patient died before operation could be performed. At post-mortem examination, the abdomen contained 2500 cc of fresh blood. The spleen was extremely soft and presented a transverse laceration in its midportion, together with several other small stellate lacerations. It is advised that great caution be observed in palpating for the spleen in an acute attack of malaria.

Although infectious mononucleosis is almost always a benign disease and is subject to few complications, it is occasionally accompanied by serious symptoms. In a case seen with Dr A. Grassi, of Haverhill, severe thrombocytopenic purpura developed, requiring splenectomy. Reports of splenic rupture are increasing in number. Davis, MacFee, Wright and Allyn¹⁸ report a typical case of the disease in a young man who was suddenly seized with sharp pain in the left upper quadrant of the abdomen and in the left shoulder and developed the symptoms of shock. At operation, a wide longitudinal split of the splenic capsule was found, together with two tears in the pulp. The splenic disease was typical of infectious mononucleosis. Recovery ensued. Other cases have been described by King,¹⁹ Darlev, Black, Smith and Good,²⁰ Ziegler²¹ and Vaughan, Regan and Terplan.²² Rupture in the last case took place with simple straining at stool. Martin²³ reports a case of ruptured aneurysm of the splenic artery.

Splenic rupture occurring spontaneously in an apparently normal spleen is reported by Duby.²⁴ A twenty-eight-year-old, married woman was suddenly seized with severe upper abdominal pain, difficult breathing and fainting. It was thought that she might have an ectopic pregnancy with rupture, and operation was therefore performed. Large amounts of intra-abdominal blood were found, and exploration revealed an enlarged, soft spleen with a large rent near the upper pole. Splenectomy was followed by recovery. The spleen weighed 340 gm and showed multiple lacerations. No cause for the rupture was obvious, and the splenic histology was unrevealing.

Splenic Tumors and Cysts and Accessory Spleens

Bostwick²⁵ reviews the 157 cases of primary neoplasms of the spleen in the literature and adds 7 of his own. Seven types are discriminated: angioma — either hemangioma or lymphangioma, lymphoma, reticuloendothelial neoplasm, embryonic inclusions, including various types of cysts, fibrosarcoma, leiomyosarcoma, and neurosarcoma.

A report from Argentina by Unchalo, Mainetti and Cuculicchio²⁶ concerns an interesting case of a

to tissue injury and played a part in the control of protein metabolism. These results, although they require amplification and confirmation, are among the first clear-cut and direct bits of evidence indicating the presence of splenic hormones.

The relation of "splenin" to "thrombocytopen," described a number of years ago by Troland and Lee,⁶ remains to be determined. It appears both from clinical studies and from the study of extracts of spleens removed from patients with idiopathic thrombocytopenic purpura that the spleen in this disease contains a material, possibly hormonal, that has distant effects on the production of platelets from the megakaryocytes of the bone marrow. Since the platelet count becomes and remains extremely high following splenectomy in the normal animal and human being, and since splenectomy in idiopathic thrombocytopenic purpura is followed by a dramatic increase in platelets, it seems reasonable to conclude that the spleen in this disease contains an excess of the normal platelet-regulating substance. Idiopathic thrombocytopenic purpura may therefore be a form of hypersplenism. The frequent presence of thrombocytopenia in patients with splenomegaly and the return of the platelet count to normal or above normal following splenectomy afford clinical confirmation of this concept. The results with the injection of splenic extracts from patients with idiopathic thrombocytopenic purpura have been inconstant, about half the investigators confirming Troland and Lee's original observations and half reporting no reduction in platelets. Recent experiments in our laboratory with dogs as the test animals indicate the presence of an active megakaryocyte-platelet inhibitor in splenic extracts from patients with the disease.⁷

Hypersplenism. The spleen normally exerts definite effects on the bone marrow, causing both quantitative and qualitative changes in the blood cells. These normal effects, however, seem to have little significance, since the splenectomized patient can live a healthy, normal life with no shortening of the life span. But under pathologic conditions the spleen may develop unusual importance and may even be detrimental to life. When the splenic physiology becomes abnormal, various effects that are concerned with the bone marrow and blood may ensue. The bone marrow produces three types of cells — red cells, granulocytes and platelets. The splenic or hypersplenic effects, so far as they can be determined, are anemia, neutropenia, thrombocytopenia and various combinations of these conditions. Hypersplenism may thus be selective or total. If total, pancytopenia is present.

Splenic thrombocytopenia is the best known of the forms of hypersplenism. In many cases idiopathic thrombocytopenic purpura occurs suddenly, but in others it is prolonged, with remissions and relapses. Recent studies of the bone marrow by Dameshek and Miller⁸ show that platelet formation by

the megakaryocytes is greatly reduced, but that following splenectomy it is greatly increased, leading to a rapid increase in the platelets in the blood. It appears that there is present in the spleen of patients with this disease an active material that causes inhibition of growth and delivery of platelets from the bone-marrow megakaryocytes to the blood. Thrombocytopenia may be primary or idiopathic, or it may be symptomatic of many conditions causing splenomegaly. Thus, in portal hypertension, — as in cirrhosis of the liver, — in disorders of fat metabolism (Gaucher's disease) and in chronic infectious splenomegaly the platelet count often becomes reduced, at times greatly so.

Splenic anemia has been discussed for years but has been largely discarded in the modern literature, chiefly because it became a blanket term covering many different disorders in which two features were present — anemia and splenomegaly. Many cases of leukemia, Cooley's anemia, sickle-cell anemia and so forth were called splenic anemia, until finally one investigator after another separated from this heterogeneous group different specific disorders. This left few conditions that could actually be designated as splenic anemia.

Abrami, De Gaudart d'Allaines and Dugas,⁹ in a recent number of the French hematologic journal *Le Sang*, advocated revival of the term "splenic anemia" to include cases with splenomegaly and anemia in which splenectomy was therapeutically successful, apparently through the removal of an inhibitory effect of the enlarged spleen. Many cases of hemolytic anemia are cured by splenectomy. In some of these the red cells are defective, in a few, usually those in which the white-cell and platelet counts are also reduced, the spleen seems to be at the central point of the disease picture and splenectomy is dramatically successful. These cases are probably examples of hypersplenism with splenic anemia. Whether the spleen exerts only a hemolytic effect in these cases or also has an effect on maturation of red cells or their delivery from the bone marrow to the blood is not yet completely clear.

Splenic neutropenia is gradually becoming better known as a definite syndrome. This condition seems to be a form of hypersplenism in which the bone-marrow granulocytes are chiefly affected. First described by Frank¹⁰ in 1916 under the term "aleukia splenica," the syndrome was revived more recently by Wiseman and Doan¹¹ under the designation "splenic neutropenia." Briefly, the combination of leukopenia, extreme granulocytopenia and splenomegaly is present. Pyogenic infections and fever are often present. Studies of the bone marrow rule out the presence of leukemia, lymphosarcoma and so forth and show increased numbers of granulocytes, despite the low granulocyte count in the blood. If the various studies and interpretations have been correct, splenectomy is followed by a

THE HEMORRHAGIC DISEASES

As in previous reviews, the following classification of the hemorrhagic diseases will be used, chiefly because it seems both simple and physiologically accurate. It is based on the thesis that loss of blood from capillaries is ordinarily controlled by an intact blood-vessel lining, by abundant platelets and by certain plasma constituents, such as prothrombin, fibrinogen and thromboplastin. Hemorrhagic diseases may therefore be classified as follows: vascular purpura, in which there is a disturbance of the blood-vessel wall, thrombocytopenic purpura, in which there is a greatly diminished number of platelets, and disturbances of blood coagulation — hemophilia, hypoprothrombinemia, fibrinopenia and so forth — in which a defect is present in one of the several blood-clotting factors.

Vascular Purpura

Bleeding into the skin in the form of ecchymoses and petechiae, unattended by a reduction of blood platelets, occurs under a variety of conditions — infectious or "toxic" — or for unknown cause. The large, purplish ecchymoses that have recently been so often observed in cases of meningococcemia are apparently due to the lodgment of meningococci in the skin capillaries and perhaps to some toxic influence on the blood-vessel walls. More frequent than these are the ecchymoses that many middle-aged women develop, particularly those with soft skins and rounded arms. These black-and-blue spots, often called "devil's pinches" because they occur spontaneously, usually appear in crops, chiefly on the thighs and arms. Their etiology is by no means obvious, although an endocrinal influence of some sort has been postulated. They have no particular significance and do not respond to vitamin, endocrine or other therapy. Of greater significance are the cases of vascular purpura in which crops of purplish ecchymoses occur about joints. These may be associated with renal disturbances. Histologic studies may disclose lesions resembling those of periarteritis nodosa. It is possible that such cases are related to such so-called "vascular" diseases as disseminated lupus erythematosus and periarteritis nodosa. There is evidence that the latter condition is a form of vascular allergy.

A blood-vessel disease that is familial and hereditary is hereditary hemorrhagic telangiectasia, first described by Osler, Rendu and Weber. Voyles and Ritchey³⁴ report 2 cases of this disease, which is characterized by the presence of multiple telangiectases, hemorrhage and anemia and a familial history. Their review of the literature disclosed 500 cases, occurring in about one hundred families. The hereditary factor is transmitted as a simple dominant and may affect either sex, atavism is occasionally noted. Epistaxes occur frequently, because the lesions that are often found in the nasal mucosa as well as in the skin and the mucous mem-

branes consist of a dilatation of a blood vessel that is covered only by a very thin layer of epithelium. Cauterization, pressure packs, iron and transfusions have been used in therapy. Recently I have successfully employed packs of synthetic fibrin foam or absorbable sponge soaked in thrombin solution (bovine) to control the bleeding in such cases. Correll, Prentice and Wise³⁵ have recently described certain biologic investigations of the new absorbable sponge developed in the research laboratories of the Upjohn Company. This material has the attributes of fibrin and can be cut into any desired size or shape, it takes up solutions such as thrombin solution readily and can be molded to fit closely any bleeding surface. The pledgets gradually become absorbed and therefore do not require removal. Rundles³⁶ describes an unusual case of hereditary telangiectasia with epistaxis, bleeding from the gastrointestinal tract due to multiple gastric telangiectases, demonstrated by gastroscopy, and an aneurysm of the pulmonary artery. At post-mortem examination, multiple small aneurysms of the splenic artery were also found.

Thrombocytopenic Purpura

Four types of thrombocytopenic purpura can be discriminated — that due to bone-marrow disease, in which the megakaryocytes are greatly diminished as part of a generalized disturbance, as in aplasia, leukemia, metastatic lymphosarcoma, fibrosis and so forth, that due to a local or selective bone-marrow disturbance in which a toxic, chemical or allergic disturbance affects the megakaryocytes and thus leads to a low platelet level, that due to the hypersplenic effects of an enlarged spleen (see above), as in cirrhosis of the liver, Gaucher's disease, chronic infectious splenitis and so forth, and idiopathic thrombocytopenic purpura, in which, although no splenic enlargement is present, there is probably a greatly disturbed splenic function.

Freeman³⁷ reports the case of a thirty-seven-year-old man with a long history of syphilis and anti-syphilitic therapy. Because of a positive serologic test, mapharsen was given and was followed after ten injections by the development of purpura and death. The blood showed extreme anemia, neutropenia and thrombocytopenia. Another case of thrombocytopenic purpura due to mapharsen is reported by Schwartz and Vonder Heide,³⁸ who stress the benign character of the disorder and the lack of bone-marrow disturbance. These are not borne out in my experience. A case of sulfathiazole purpura is reported by Strong and Glassburn.³⁹ This patient had scarlet fever and was treated with sulfathiazole. After 19 gm had been given, thrombocytopenic purpura developed. Scarlet fever per se is only rarely the cause of thrombocytopenia. Rappaport, Nixon and Barker⁴⁰ report the case of a thirty-seven-year-old man who was treated for rheumatoid arthritis with large doses of sodium

young woman with fever, cough, weight loss and an enlarged spleen whose sputum contained the hooks of *Taenia echinococcus*. At operation, a large cyst replacing the spleen was found. Formalization and marsupialization were performed without splenectomy. Almost three years later, another abdominal operation was required and exploration disclosed complete absence of the spleen in the left hypochondrium, with a thick irregular process adherent to the diaphragm and the tail of the pancreas. There had been no recurrence of the hydatid cyst. Another interesting case report of a splenic cyst is that of Jameson and Smith,³⁷ who described a calcified cyst in an eighteen-year-old student complaining of left upper abdominal pain. X-ray films showed a partially calcified mass in the left upper quadrant, not connected with the stomach or the kidneys. Operation revealed an enlarged spleen that was replaced in large part by a calcified cyst. Splenic cysts are rare, only 152 cases of all types having been reported up to 1941, calcification has been reported in only 7 cases. In a case personally observed, a large mass in the upper abdomen, particularly prominent on the left, was thought to be of splenic origin because the white-cell count was low and contraction occurred following the injection of adrenalin. Operation disclosed an extremely large unilocular cyst, which was removed in toto, with complete recovery.

Accessory spleens may be an extremely annoying feature following splenectomy, particularly in idiopathic thrombocytopenic purpura and hemolytic anemia. Recurrences in such conditions may be due to the abnormal activity of such a splenunculus. Rhame²⁸ reports the case of a young man requiring abdominal operation whose spleen had been removed six years previously for traumatic rupture. Exploration revealed a tumor in the midjejunum under the serosa of the antimesenteric border of the bowel, impinging on the bowel lumen. Several similar smaller tumors were found along the greater curvature of the stomach and the lower margin of the transverse colon and in the greater omentum. Microscopically, all the specimens removed were hyperplastic hemolymph nodes, having the appearance of splenic tissue except for the trabeculae. It is considered that, in the young, splenic function may be restored after splenectomy, through hypertrophy of hemolymph nodes and by accessory splenic tissue. An unusual location for an accessory spleen is described by Olken,³⁹ who at autopsy in a fifty-six-year-old man who had died of a bleeding peptic ulcer found a tail of accessory splenic tissue that passed through the inguinal canal into the scrotum, where a bulb of splenic tissue was located.

Splenectomy

The indications for splenectomy are discussed in a series of letters in *Modern Medicine* for May, 1945. These letters were solicited in response to the abstract of an article by Carpenter³⁰ reviewed in the

same publication in March, 1945. Dameshek classifies indications as absolute, probable and possible. The first are rupture of the spleen, idiopathic thrombocytopenic purpura,³⁰ particularly if acute, familial hemolytic jaundice of the spherocytic variety if one or more crises have occurred, acute or subacute hemolytic anemia if a few transfusions have proved ineffective and if various specific causes for the increased hemolysis have been ruled out, and tumors and cysts of the spleen, if properly diagnosed. The *probable* indications include certain cases of splenic neutropenia, certain cases of Mediterranean sickle-cell anemia with unusual degrees of hemolysis and certain cases of splenic disease with pancytopenia. The *possible* indications comprise certain cases of chronic congestive splenomegaly, including cirrhosis of the liver and so forth, particularly those with leukopenia and thrombocytopenia. Doan, in the same symposium, lists the following indications: congenital hemolytic icterus, thrombocytopenic purpura hemorrhagica in which the marrow shows increased megakaryocytes, primary splenic neutropenia, primary splenic panhematopenia and any other type of splenomegaly associated with anemia or leukopenia, with or without thrombocytopenia. Doan's criteria for splenectomy are based essentially on the laboratory studies centered in sternal-marrow aspiration, with supravital studies of the removed cells, and the adrenalin test for splenic contraction. The latter, Doan believes, gives a biopsy, as it were, of the cells sequestered by the spleen. He thinks that in idiopathic thrombocytopenic purpura and splenic neutropenia the spleen sequesters cells rather than causing inhibitory effects on the bone marrow.

Cooley,³¹ in the last article published before his death in October, 1945, described a new refractory hypochromic anemia, associated with elliptocytosis, which was unresponsive to liver and iron therapy and was present as a familial trait. There was apparently no Mediterranean or Negro admixture and no evidence of increased hemolysis. Splenectomy in 1 case resulted in slow, steady improvement. Cooley suggested that there is a group of anemias in which a defective type of hemoglobin or red-cell formation is present and in which there is a splenic influence on the bone marrow.

Pappenheimer, Thompson, Parker and Smith³² report 3 cases of a severe form of hypochromic anemia, possibly hemolytic, not responding to liver or iron, in which splenectomy was performed. Two patients died of progressive anemia after splenectomy, in the third case the anemia was unchanged. Following splenectomy, all patients showed in the red cells small iron-staining coccoid or bacilloid bodies having a superficial resemblance to Bartonella parasites. It was concluded that the bodies were probably analogous to the so-called "siderocytes" previously described by Grüneberg.³³

THE HEMORRHAGIC DISEASES

As in previous reviews, the following classification of the hemorrhagic diseases will be used, chiefly because it seems both simple and physiologically accurate. It is based on the thesis that loss of blood from capillaries is ordinarily controlled by an intact blood-vessel lining, by abundant platelets and by certain plasma constituents, such as prothrombin, fibrinogen and thromboplastin. Hemorrhagic diseases may therefore be classified as follows: vascular purpura, in which there is a disturbance of the blood-vessel wall, thrombocytopenic purpura, in which there is a greatly diminished number of platelets, and disturbances of blood coagulation — hemophilia, hypoprothrombinemia, fibrinopenia and so forth — in which a defect is present in one of the several blood-clotting factors.

Vascular Purpura

Bleeding into the skin in the form of ecchymoses and petechiae, unattended by a reduction of blood platelets, occurs under a variety of conditions — infectious or "toxic" — or for unknown cause. The large, purplish ecchymoses that have recently been so often observed in cases of meningococcemia are apparently due to the lodgment of meningococci in the skin capillaries and perhaps to some toxic influence on the blood-vessel walls. More frequent than these are the ecchymoses that many middle-aged women develop, particularly those with soft skins and rounded arms. These black-and-blue spots, often called "devil's pinches" because they occur spontaneously, usually appear in crops, chiefly on the thighs and arms. Their etiology is by no means obvious, although an endocrinal influence of some sort has been postulated. They have no particular significance and do not respond to vitamin, endocrine or other therapy. Of greater significance are the cases of vascular purpura in which crops of purplish ecchymoses occur about joints. These may be associated with renal disturbances. Histologic studies may disclose lesions resembling those of periarteritis nodosa. It is possible that such cases are related to such so-called "vascular" diseases as disseminated lupus erythematosus and periarteritis nodosa. There is evidence that the latter condition is a form of vascular allergy.

A blood-vessel disease that is familial and hereditary is hereditary hemorrhagic telangiectasia, first described by Osler, Rendu and Weber. Vovles and Ritchey³⁴ report 2 cases of this disease, which is characterized by the presence of multiple telangiectases, hemorrhage and anemia and a familial history. Their review of the literature disclosed 500 cases, occurring in about one hundred families. The hereditary factor is transmitted as a simple dominant and may affect either sex, atavism is occasionally noted. Epistaxes occur frequently, because the lesions that are often found in the nasal mucosa as well as in the skin and the mucous mem-

branes consist of a dilatation of a blood vessel that is covered only by a very thin layer of epithelium. Cauterization, pressure packs, iron and transfusions have been used in therapy. Recently I have successfully employed packs of synthetic fibrin foam or absorbable sponge soaked in thrombin solution (bovine) to control the bleeding in such cases. Exploration revealed a tumor in the midjejunum under the serosa of the antimesenteric border of the bowel, impinging on the bowel lumen. Several similar smaller tumors were found along the greater curvature of the stomach and the lower margin of the transverse colon and in the greater omentum. Microscopically, all the specimens removed were hyperplastic hemolymph nodes, having the appearance of splenic tissue except for the trabeculae. It is considered that, in the young, splenic function may be restored after splenectomy, through hypertrophy of hemolymph nodes and by accessory splenic tissue. An unusual location for an accessory spleen is described by Olken,²⁹ who at autopsy in a fifty-six-year-old man who had died of a bleeding peptic ulcer found a tail of accessory splenic tissue that passed through the inguinal canal into the scrotum, where a bulb of splenic tissue was located.

Splenectomy

The indications for splenectomy are discussed in a series of letters in *Modern Medicine* for May, 1945. These letters were solicited in response to the abstract of an article by Carpenter³⁰ reviewed in the

same publication in March, 1945. Dameshek classifies indications as absolute, probable and possible. The first are rupture of the spleen, idiopathic thrombocytopenic purpura, particularly if acute, familial hemolytic jaundice of the spherocytic variety if one or more crises have occurred, acute or subacute hemolytic anemia if a few transfusions have proved ineffective and if various specific causes for the increased hemolysis have been ruled out, and tumors and cysts of the spleen, if properly diagnosed. The *probable* indications include certain cases of splenic neutropenia, certain cases of Mediterranean sickle-cell anemia with unusual degrees of hemolysis and certain cases of splenic disease with pancytopenia. The *possible* indications comprise certain cases of chronic congestive splenomegaly, including cirrhosis of the liver and so forth, particularly those with leukopenia and thrombocytopenia. Doan, in the same symposium, lists the following indications: congenital hemolytic icterus, thrombocytopenic purpura hemorrhagica in which the marrow shows increased megakaryocytes, primary splenic neutropenia, primary splenic panhematopenia and any other type of splenomegaly associated with anemia or leukopenia, with or without thrombocytopenia. Doan's criteria for splenectomy are based essentially on the laboratory studies centered in sternal-marrow aspiration, with supravital studies of the removed cells, and the adrenalin test for splenic contraction. The latter, Doan believes, gives a biopsy, as it were, of the cells sequestered by the spleen. He thinks that in idiopathic thrombocytopenic purpura and splenic neutropenia the spleen sequesters cells rather than causing inhibitory effects on the bone marrow.

Cooley,³¹ in the last article published before his death in October, 1945, described a new refractory hypochromic anemia, associated with elliptocytosis, which was unresponsive to liver and iron therapy and was present as a familial trait. There was apparently no Mediterranean or Negro admixture and no evidence of increased hemolysis. Splenectomy in 1 case resulted in slow, steady improvement. Cooley suggested that there is a group of anemias in which a defective type of hemoglobin or red-cell formation is present and in which there is a splenic influence on the bone marrow.

Pappenheimer, Thompson, Parker and Smith³² report 3 cases of a severe form of hypochromic anemia, possibly hemolytic, not responding to liver or iron, in which splenectomy was performed. Two patients died of progressive anemia after splenectomy, in the third case the anemia was unchanged. Following splenectomy, all patients showed in the red cells small iron-staining coccoid or bacilloid bodies having a superficial resemblance to Bartonella parasites. It was concluded that the bodies were probably analogous to the so-called "siderocytes" previously described by Gruneberg.³³

THE HEMORRHAGIC DISEASES

As in previous reviews, the following classification of the hemorrhagic diseases will be used, chiefly because it seems both simple and physiologically accurate. It is based on the thesis that loss of blood from capillaries is ordinarily controlled by an intact blood-vessel lining, by abundant platelets and by certain plasma constituents, such as prothrombin, fibrinogen and thromboplastin. Hemorrhagic diseases may therefore be classified as follows: vascular purpura, in which there is a disturbance of the blood-vessel wall, thrombocytopenic purpura, in which there is a greatly diminished number of platelets, and disturbances of blood coagulation — hemophilia, hypoprothrombinemia, fibrinopenia and so forth — in which a defect is present in one of the several blood-clotting factors.

Vascular Purpura

Bleeding into the skin in the form of ecchymoses and petechiae, unattended by a reduction of blood platelets, occurs under a variety of conditions — infectious or "toxic" — or for unknown cause. The large, purplish ecchymoses that have recently been so often observed in cases of meningococcemia are apparently due to the lodgment of meningococci in the skin capillaries and perhaps to some toxic influence on the blood-vessel walls. More frequent than these are the ecchymoses that many middle-aged women develop, particularly those with soft skins and rounded arms. These black-and-blue spots, often called "devil's pinches" because they occur spontaneously, usually appear in crops, chiefly on the thighs and arms. Their etiology is by no means obvious, although an endocrinal influence of some sort has been postulated. They have no particular significance and do not respond to vitamin, endocrine or other therapy. Of greater significance are the cases of vascular purpura in which crops of purplish ecchymoses occur about joints. These may be associated with renal disturbances. Histologic studies may disclose lesions resembling those of periarteritis nodosa. It is possible that such cases are related to such so-called "vascular" diseases as disseminated lupus erythematosus and periarteritis nodosa. There is evidence that the latter condition is a form of vascular allergy.

A blood-vessel disease that is familial and hereditary is hereditary hemorrhagic telangiectasia, first described by Osler, Rendu and Weber. Voyles and Ritchey²¹ report 2 cases of this disease, which is characterized by the presence of multiple telangiectases, hemorrhage and anemia and a familial history. Their review of the literature disclosed 500 cases, occurring in about one hundred families. The hereditary factor is transmitted as a simple dominant and may affect either sex, atavism is occasionally noted. Epistaxes occur frequently, because the lesions that are often found in the nasal mucosa as well as in the skin and the mucous mem-

branes consist of a dilatation of a blood vessel that is covered only by a very thin layer of epithelium. Cauterization, pressure packs, iron and transfusions have been used in therapy. Recently I have successfully employed packs of synthetic fibrin foam or absorbable sponge soaked in thrombin solution (bovine) to control the bleeding in such cases. Correll, Prentice and Wise²² have recently described certain biologic investigations of the new absorbable sponge developed in the research laboratories of the Upjohn Company. This material has the attributes of fibrin and can be cut into any desired size or shape, it takes up solutions such as thrombin solution readily and can be molded to fit closely any bleeding surface. The pledgets gradually become absorbed and therefore do not require removal. Rundles²³ describes an unusual case of hereditary telangiectasia with epistaxis, bleeding from the gastrointestinal tract due to multiple gastric telangiectases, demonstrated by gastroscopy, and an aneurysm of the pulmonary artery. At post-mortem examination, multiple small aneurysms of the splenic artery were also found.

Thrombocytopenic Purpura

Four types of thrombocytopenic purpura can be discriminated — that due to bone-marrow disease, in which the megakaryocytes are greatly diminished as part of a generalized disturbance, as in aplasia, leukemia, metastatic lymphosarcoma, fibrosis and so forth, that due to a local or selective bone-marrow disturbance in which a toxic, chemical or allergic disturbance affects the megakaryocytes and thus leads to a low platelet level, that due to the hypersplenic effects of an enlarged spleen (see above), as in cirrhosis of the liver, Gaucher's disease, chronic infectious splenitis and so forth, and idiopathic thrombocytopenic purpura, in which, although no splenic enlargement is present, there is probably a greatly disturbed splenic function.

Freeman²⁴ reports the case of a thirty-seven-year-old man with a long history of syphilis and anti-syphilitic therapy. Because of a positive serologic test, mapharsen was given and was followed after ten injections by the development of purpura and death. The blood showed extreme anemia, neutropenia and thrombocytopenia. Another case of thrombocytopenic purpura due to mapharsen is reported by Schwartz and Vonder Heide,²⁵ who stress the benign character of the disorder and the lack of bone-marrow disturbance. These are not borne out in my experience. A case of sulfathiazole purpura is reported by Strong and Glassburn.²⁶ This patient had scarlet fever and was treated with sulfathiazole. After 19 gm had been given, thrombocytopenic purpura developed. Scarlet fever per se is only rarely the cause of thrombocytopenia. Rappaport, Nixon and Barker¹⁰ report the case of a thirty-seven-year-old man who was treated for rheumatoid arthritis with large doses of sodium

young woman with fever, cough, weight loss and an enlarged spleen whose sputum contained the hooks of *Taenia echinococcus*. At operation, a large cyst replacing the spleen was found. Formalization and marsupialization were performed without splenectomy. Almost three years later, another abdominal operation was required and exploration disclosed complete absence of the spleen in the left hypochondrium, with a thick irregular process adherent to the diaphragm and the tail of the pancreas. There had been no recurrence of the hydatid cyst. Another interesting case report of a splenic cyst is that of Jameson and Smith,²⁷ who described a calcified cyst in an eighteen-year-old student complaining of left upper abdominal pain. X-ray films showed a partially calcified mass in the left upper quadrant, not connected with the stomach or the kidneys. Operation revealed an enlarged spleen that was replaced in large part by a calcified cyst. Splenic cysts are rare, only 152 cases of all types having been reported up to 1941, calcification has been reported in only 7 cases. In a case personally observed, a large mass in the upper abdomen, particularly prominent on the left, was thought to be of splenic origin because the white-cell count was low and contraction occurred following the injection of adrenalin. Operation disclosed an extremely large unilocular cyst, which was removed in toto, with complete recovery.

Accessory spleens may be an extremely annoying feature following splenectomy, particularly in idiopathic thrombocytopenic purpura and hemolytic anemia. Recurrences in such conditions may be due to the abnormal activity of such a splenunculus. Rhame²⁸ reports the case of a young man requiring abdominal operation whose spleen had been removed six years previously for traumatic rupture. Exploration revealed a tumor in the midjejunum under the serosa of the antimesenteric border of the bowel, impinging on the bowel lumen. Several similar smaller tumors were found along the greater curvature of the stomach and the lower margin of the transverse colon and in the greater omentum. Microscopically, all the specimens removed were hyperplastic hemolymph nodes, having the appearance of splenic tissue except for the trabeculae. It is considered that, in the young, splenic function may be restored after splenectomy, through hypertrophy of hemolymph nodes and by accessory splenic tissue. An unusual location for an accessory spleen is described by Olken,²⁹ who at autopsy in a fifty-six-year-old man who had died of a bleeding peptic ulcer found a tail of accessory splenic tissue that passed through the inguinal canal into the scrotum, where a bulb of splenic tissue was located.

Splenectomy

The indications for splenectomy are discussed in a series of letters in *Modern Medicine* for May, 1945. These letters were solicited in response to the abstract of an article by Carpenter³⁰ reviewed in the

same publication in March, 1945. Dameshek classifies indications as absolute, probable and possible. The first are rupture of the spleen, idiopathic thrombocytopenic purpura,³¹ particularly if acute, familial hemolytic jaundice of the spherocytic variety if one or more crises have occurred, acute or subacute hemolytic anemia if a few transfusions have proved ineffective and if various specific causes for the increased hemolysis have been ruled out, and tumors and cysts of the spleen, if properly diagnosed. The *probable* indications include certain cases of splenic neutropenia, certain cases of Mediterranean sickle-cell anemia with unusual degrees of hemolysis and certain cases of splenic disease with pancytopenia. The *possible* indications comprise certain cases of chronic congestive splenomegaly, including cirrhosis of the liver and so forth, particularly those with leukopenia and thrombocytopenia. Doan, in the same symposium, lists the following indications: congenital hemolytic icterus, thrombocytopenic purpura hemorrhagica in which the marrow shows increased megakaryocytes, primary splenic neutropenia, primary splenic panhematopenia and any other type of splenomegaly associated with anemia or leukopenia, with or without thrombocytopenia. Doan's criteria for splenectomy are based essentially on the laboratory studies centered in sternal-marrow aspiration, with supravital studies of the removed cells, and the adrenalin test for splenic contraction. The latter, Doan believes, gives a biopsy, as it were, of the cells sequestered by the spleen. He thinks that in idiopathic thrombocytopenic purpura and splenic neutropenia the spleen sequesters cells rather than causing inhibitory effects on the bone marrow.

Cooley,³¹ in the last article published before his death in October, 1945, described a new refractory hypochromic anemia, associated with elliptocytosis, which was unresponsive to liver and iron therapy and was present as a familial trait. There was apparently no Mediterranean or Negro admixture and no evidence of increased hemolysis. Splenectomy in 1 case resulted in slow, steady improvement. Cooley suggested that there is a group of anemias in which a defective type of hemoglobin or red-cell formation is present and in which there is a splenic influence on the bone marrow.

Pappenheimer, Thompson, Parker and Smith³² report 3 cases of a severe form of hypochromic anemia, possibly hemolytic, not responding to liver or iron, in which splenectomy was performed. Two patients died of progressive anemia after splenectomy, in the third case the anemia was unchanged. Following splenectomy, all patients showed in the red cells small iron-staining coccoid or bacilloid bodies having a superficial resemblance to Bartonella parasites. It was concluded that the bodies were probably analogous to the so-called "siderocytes" previously described by Gruneberg.³³

may be of some therapeutic value when the blood prothrombin time becomes excessively increased with dicumarol therapy. Otherwise transfusions of fresh blood and large amounts of vitamin K are routinely used. Field and Link⁴⁹ found that the administration of large amounts of vitamin K protected rats against the action of dicumarol and in fact induced a temporary state of hyperprothrombinemia. Large amounts of 2-methyl-1, 4-naphthoquinone when administered to dogs, rabbits and rats were productive of hyperprothrombinemia lasting for several days. According to the observations of Spooner and Meyer,⁵⁰ dicumarol apparently not only affects the prothrombin time but also causes a reduction in platelet adhesiveness.

Fibrinopenia The rarest form of coagulation defect is that due to fibrinopenia or fibrinogenopenia. Henderson, Donaldson and Scarborough⁵¹ report such a case. The principal features of this hemorrhagic disease are its hereditary character, a high evidence of consanguinity in the parents, its presence in both sexes, a total absence of fibrinogen in the blood and complete incoagulability of the blood. The disorder is probably caused by a hereditary defect in fibrinogen formation. Acquired cases, in which the disorder is due to a toxic or neoplastic interference with fibrinogen formation by the liver and bone marrow, may occur.

Other disorders of coagulation Pseudothrombophilia is a hemorrhagic disorder that is occasionally encountered and that does not fit well into any one of the above groups. There is an increased tendency toward bleeding from minor wounds, the only constant defect found is a distinct increase in the bleeding time. The coagulation time may be slightly prolonged, and the recalcified clotting time may also be increased. The platelets are normal. Therapy by transfusions, splenectomy and so forth is without effect.

Evans and MacLaren⁵² report the case history of a thirty-nine-year-old man who suffered bleeding from the skin, mucosa, and viscera. This disorder, they state, is a hereditary one affecting both males and females for at least four generations. No disturbances in coagulation time, bleeding time, prothrombin time or platelet count were present.

Penicillin and Blood Coagulation

Moldavsky, Hasselbrock, Cateno and Goodwin⁵³ studied the effect of penicillin on the coagulation, bleeding and prothrombin times in 20 patients. A marked reduction in coagulation time occurred in inverse ratio to the penicillin concentration. No change in prothrombin time took place. These authors suggest that penicillin is conducive to thrombus formation and may therefore be useful as a coagulant in certain hemorrhagic disorders. On the other hand, Hines and Kessler⁵⁴ found that penicillin sometimes caused a great increase in the effect of heparin in 2 cases of subacute bacterial endocarditis in which the latter drug was given as an adjuvant.

Influence of the Contacting Surface on Coagulability of the Blood

When blood is placed in a glass test tube, it clots normally in fifteen to twenty minutes, which is considered the normal coagulation time. It should be remembered, however, that this is an artificial method for determining coagulation, the blood vascular apparatus being something far different from glass. The smooth endothelial surfaces of the capillaries probably hinder blood coagulation. Tocantins⁵⁵ studied various materials from the standpoint of their effect on coagulation and demonstrated wide variations. For example, blood clotted much faster in glass than in the plastic lusteroid. This difference, which is greatly accentuated in hemophilic blood, is due, Tocantins concludes, to an excess of so-called "anticephalin" in the blood of hemophilia. He proposes this as another differential feature, particularly in mild cases of true hemophilia.

ANEMIA

A simplified classification of anemia was presented in last year's review.⁵⁶ Briefly, all cases of anemia may be divided into those due to a deficiency of the materials necessary for blood formation, — the deficiency anemias, — those due to a disturbed function of the bone-marrow production centers — aplastic and myelophthisic anemias — and those due to an increased loss or destruction of red cells — the hemorrhagic and the hemolytic anemias. A combination of this etiologic type of classification with one relating to cell size or color index is often useful in working out diagnostic leads, especially when it is realized that the anemia is merely a symptom indicating some sort of underlying disturbance.

Deficiency Anemias

Under the deficiency anemias are included liver-extract deficiency (pernicious anemia), iron deficiency, vitamin B deficiency and certain other conditions including sprue and tropical macrocytic anemia. In pernicious anemia, search has continued for the actual factor that is effective in relieving the liver-extract deficiency state. According to many recent reports, folic acid — a fraction of the vitamin B complex — may be the long-looked-for substance. One of the first reports in a medical journal on the use of this substance is that by Moore et al.,⁵⁷ who treated 2 cases of pernicious anemia with folic acid. Since then, many reports, official and unofficial, have shown conclusively that only a relatively few milligrams of folic acid are enough to induce a complete remission and maintain the blood counts at or near normal levels. A series of previous reports indicated that certain patients refractory to highly potent injectable liver extract might respond to the oral administration of large amounts of crude or proteolyzed liver extract. Thus, Watson and Castle⁵⁸ made observations on 3 women with nutritional macrocytic anemia, 2 of them were preg-

salicylate The drug was discontinued and was resumed three weeks later Severe hemorrhages ensued in association with a low platelet level The megakaryocytes in the bone marrow were immature, with vacuolated cytoplasm and pyknotic nuclei Splenectomy was performed, but the patient died It is concluded that this was a case of allergic reaction to sodium salicylate with a direct toxic effect on the bone-marrow megakaryocytes In the absence of any evidence of hypersplenism, splenectomy could hardly be expected to have had an effect in such cases

Schwartz⁴¹ describes the diagnostic and prognostic value of eosinophilia in the bone marrow in cases of thrombocytopenic purpura He believes that if the eosinophils exceed an arbitrary base line of 50 in relation to 1000 leukocytes of the metamyelocyte-polymorphonuclear series, the thrombocytopenia is of an allergic nature and will improve spontaneously without splenectomy With low eosinophil counts, however, spontaneous improvement is unlikely and splenectomy will probably be required Although these conclusions are based on the analysis of a fairly large series of cases, 30 in all, they require confirmation Nevertheless, the paper serves a highly useful purpose in directing attention to the possibility that certain cases of idiopathic thrombocytopenic purpura are allergic in nature According to our own experience,⁸ the megakaryocytes in idiopathic thrombocytopenic purpura are increased but platelet formation is greatly diminished Following splenectomy, there is a remarkable increase in platelet formation by the megakaryocytes When there is active bleeding, the postponement of splenectomy may prove disastrous, because of bleeding into vital structures Carelli and Cangelosi⁴² report a case of idiopathic thrombocytopenic purpura in which total blindness occurred, with active bleeding Splenectomy performed when the bleeding had become quiescent was productive of a rapid increase in platelets, but no improvement in the optic atrophy occurred This case points a valuable moral although there is some danger in splenectomy in acute thrombocytopenic purpura, it is usually better to accept it than to adopt a waiting policy

Disturbances of Blood Coagulation

Hemophilia It seems likely that methods for keeping in check the dread disease hemophilia will shortly be available The plasma-fractionation methods developed by Cohn and his collaborators at the Harvard Medical School have yielded an antihemophilic substance that has already been used experimentally by several groups of investigators At the Thorndike Memorial Laboratory, where much work on hemophilia has already been done, Minot et al⁴³ report on the effects of so-called "Fraction I" of plasma, which contains 60 per cent of fibrinogen, in 16 cases of hemophilia In 15 of these, the intravenous or intramuscular administration of

115 to 125 mg of the material was followed by a quick return of the coagulation time to normal Fibrinogen alone is without effect Intramuscular injections are at present associated with much pain Further work on this and other fractions is awaited with much interest, and it may well be that before long the hemophilic patient will be able to give himself daily injections of the deficient plasma fraction and thus maintain his coagulation time at normal values

Occasional cases resembling hemophilia occur in women One such case is reported by Madison and Quick⁴⁴ The patient had numerous serious hemorrhagic episodes All the features in this case except one — the recalcified coagulation time — were identical with those of hemophilia Quick had previously shown that the latter test is useful in differentiating a mild coagulation defect from true hemophilia In hemophilia, the rapid centrifugation of oxalated hemophilic blood, followed by recalcification of the plasma, is productive of slow coagulation, whereas with slow centrifugation rapid coagulation occurs In other hemorrhagic conditions, this difference does not occur

Hypoprothrombinemia The prolongation of the prothrombin time by the continued administration of salicylates was the subject of editorial comment in the *Journal of the American Medical Association*⁴⁵ Salicylates in large doses appear to act in a fashion similar to that of dicumarol and may thus cause a reduction in circulating prothrombin Severe cases of salicylate-induced hypoprothrombinemia may be associated with hemorrhage Large doses of vitamin K may either prevent the development of prothrombin deficiency or hasten its disappearance Pirk and Engelberg⁴⁶ found that quinine in ordinary dosage prolonged the prothrombin time, and suggested that the administration of vitamin K might be prophylactically beneficial in troops suffering bleeding wounds who were taking this drug An example of the rare condition of idiopathic hypoprothrombinemia is reported by Austin and Quastler⁴⁷ In this case severe and finally fatal hemorrhages took place All other causes of hypoprothrombinemia — deficiency of vitamin K, hepatic damage and dicumarol poisoning — had been ruled out

Hypothrombinemia continues to be utilized in some clinics as a prophylactic therapeutic method for the prevention of thrombosis following operation Dicumarol, the active principle causing sweet-clover disease in cattle, causes prolongation of both the prothrombin and coagulation times By careful observation of both these factors during administration of the drug, it is possible to maintain the coagulation times at high levels and thus minimize the dangers of thrombosis The dangers of hemorrhage have, however, not been fully controlled Jaques and Dunlop⁴⁸ noted that increases in the prothrombin time induced by dicumarol in rats could be shortened by adding calcium This

may be of some therapeutic value when the blood prothrombin time becomes excessively increased with dicumarol therapy. Otherwise transfusions of fresh blood and large amounts of vitamin K are routinely used. Field and Link⁴⁹ found that the administration of large amounts of vitamin K protected rats against the action of dicumarol and in fact induced a temporary state of hyperprothrombinemia. Large amounts of 2-methyl-1, 4-naphthoquinone when administered to dogs, rabbits and rats were productive of hyperprothrombinemia lasting for several days. According to the observations of Spooner and Meyer,⁵⁰ dicumarol apparently not only affects the prothrombin time but also causes a reduction in platelet adhesiveness.

Fibrinopenia The rarest form of coagulation defect is that due to fibrinopenia or fibrinogenopenia. Henderson, Donaldson and Scarborough⁵¹ report such a case. The principal features of this hemorrhagic disease are its hereditary character, a high evidence of consanguinity in the parents, its presence in both sexes, a total absence of fibrinogen in the blood and complete incoagulability of the blood. The disorder is probably caused by a hereditary defect in fibrinogen formation. Acquired cases, in which the disorder is due to a toxic or neoplastic interference with fibrinogen formation by the liver and bone marrow, may occur.

Other disorders of coagulation Pseudothrombophilia is a hemorrhagic disorder that is occasionally encountered and that does not fit well into any one of the above groups. There is an increased tendency toward bleeding from minor wounds, the only constant defect found is a distinct increase in the bleeding time. The coagulation time may be slightly prolonged, and the recalcified clotting time may also be increased. The platelets are normal. Therapy by transfusions, splenectomy and so forth is without effect.

Evans and MacLaren⁵² report the case history of a thirty-nine-year-old man who suffered bleeding from the skin, mucosa, and viscera. This disorder, they state, is a hereditary one affecting both males and females for at least four generations. No disturbances in coagulation time, bleeding time, prothrombin time or platelet count were present.

Penicillin and Blood Coagulation

Moldavsky, Hasselbrock, Cateno and Goodwin⁵³ studied the effect of penicillin on the coagulation, bleeding and prothrombin times in 20 patients. A marked reduction in coagulation time occurred in inverse ratio to the penicillin concentration. No change in prothrombin time took place. These authors suggest that penicillin is conducive to thrombus formation and may therefore be useful as a coagulant in certain hemorrhagic disorders. On the other hand, Hines and Kessler⁵⁴ found that the penicillin sometimes caused a great increase in the effect of heparin in 2 cases of subacute bacterial endocarditis in which the latter drug was given as an adjunct.

Influence of the Contacting Surface on Coagulability of the Blood

When blood is placed in a glass test tube, it clots normally in fifteen to twenty minutes, which is considered the normal coagulation time. It should be remembered, however, that this is an artificial method for determining coagulation, the blood vascular apparatus being something far different from glass. The smooth endothelial surfaces of the capillaries probably hinder blood coagulation. Tocantins⁵⁵ studied various materials from the standpoint of their effect on coagulation and demonstrated wide variations. For example, blood clotted much faster in glass than in the plastic lusteroid. This difference, which is greatly accentuated in hemophilic blood, is due, Tocantins concludes, to an excess of so-called "anticephalin" in the blood of hemophilia. He proposes this as another differential feature, particularly in mild cases of true hemophilia.

ANEMIA

A simplified classification of anemia was presented in last year's review.⁵⁶ Briefly, all cases of anemia may be divided into those due to a deficiency of the materials necessary for blood formation, — the deficiency anemias, — those due to a disturbed function of the bone-marrow production centers — aplastic and myelophthisic anemias — and those due to an increased loss or destruction of red cells — the hemorrhagic and the hemolytic anemias. A combination of this etiologic type of classification with one relating to cell size or color index is often useful in working out diagnostic leads, especially when it is realized that the anemia is merely a symptom indicating some sort of underlying disturbance.

Deficiency Anemias

Under the deficiency anemias are included liver-extract deficiency (pernicious anemia), iron deficiency, vitamin B deficiency and certain other conditions including sprue and tropical macrocytic anemia. In pernicious anemia, search has continued for the actual factor that is effective in relieving the liver-extract deficiency state. According to many recent reports, folic acid — a fraction of the vitamin B complex — may be the long-looked-for substance. One of the first reports in a medical journal on the use of this substance is that by Moore et al.,⁵⁷ who treated 2 cases of pernicious anemia with folic acid. Since then, many reports, official and unofficial, have shown conclusively that only a relatively few milligrams of folic acid are enough to induce a complete remission and maintain the blood counts at or near normal levels. A series of previous reports indicated that certain patients refractory to highly potent injectable liver extract might respond to the oral administration of large amounts of crude or proteolyzed liver extract. Thus, Watson and Castle⁵⁸ made observations on 3 women with nutritional macrocytic anemia, 2 of them were preg-

nant, and their cases would ordinarily have been classified as pernicious anemia of pregnancy. In all 3 cases, highly concentrated injectable liver extract was without effect, whereas large amounts of crude liver extract given orally were quite effective. Davis⁵⁹ reports somewhat similar observations in 3 cases of macrocytic anemia in children, proteolyzed liver given orally was rapidly effective. These observations are extended by Davis and Davidson⁶⁰ who successfully treated 15 apparently typical cases of pernicious anemia with oral proteolyzed liver after therapy with a parenteral liver extract preparation had proved unsuccessful. They conclude that proteolyzed — actually whole crude — liver contains a factor of hemopoietic value lacking in fractionated or concentrated liver extract. According to recent data, this unknown factor may be folic acid. The upshot of these several observations is that if one is reasonably certain that the macrocytic anemia in a given case is on a deficiency basis, therapy with either folic acid or crude liver extract should be used. Whether folic acid represents the entire answer to the therapy of pernicious anemia, and for that matter of all the deficiency states associated with macrocytic anemia, remains to be seen. This is particularly important with reference to the neurologic phenomena of pernicious anemia.

An important complication in pernicious anemia is the development of polyposis and gastric carcinoma. Polyps seem to form rather readily in the atrophied gastric mucosa of patients with the disease, and malignant degeneration of the polyps is fairly frequent. From a statistical study of 293 post-mortem cases of pernicious anemia, Kaplan and Rigler⁶¹ concluded that gastric carcinoma is three times as frequent in this group as in the general run of autopsied cases, the actual incidence being 12 per cent. It is suggested that frequent x-ray examination of the gastrointestinal tract be performed in cases of pernicious anemia.

The interesting pernicious anemia of pregnancy is discussed in an excellent and well documented article by Callender,⁶² based on a study of 25 cases. Excessive vomiting or diarrhea suggesting toxemia of pregnancy is frequent. The patient is not usually icteric, and changes in the tongue often occur. The blood picture is by no means typical, but the bone marrow usually shows the characteristic megaloblastic appearance of liver-extract deficiency. The gastric juice generally shows free hydrochloric acid. In addition to these atypical features, most patients are refractory to liver extract, and transfusions are often required. It is already indicated that folic acid will become the therapy of choice.

Hemolytic Anemias

Life span of the red cell. A number of articles dealing with the longevity of the red cell have appeared. Callender, Powell and Wits,⁶³ by the method of differential agglutination, determined that the average life span of the human erythro-

cyte is one hundred and twenty days — that is, that 0.83 per cent of the circulation is replaced daily. Harne, Lutz, Zimmerman and Davis⁶⁴ studied the life span of the red cells of monkeys by observing reticulocyte showers after hemorrhage and found it to be ninety-four to one hundred and seventeen days. Singer and Weisz⁶⁵ studied the same problem in the erythrocytes of dogs by observing the output of bile pigment in biliary fistulas of the renal type. By this method the average life span was found to be one hundred and ten days. In another article, Singer⁶⁶ reviews the various methods for determining the life span of the red cell and suggests that determination of this factor may be important in studying hemolytic anemia. By methods of cross determination — that is, by studying the survival time of normal red cells in the patient's circulation and that of his red cells in a normal circulation — it would be possible to demonstrate in a given hemolytic disorder whether the fundamental defect lay in the red cell itself or was extracellular.

The maturation of reticulocytes within the circulation was studied by Young and Lawrence,⁶⁷ who injected 150 cc of blood containing 73 per cent reticulocytes into a child with aplastic anemia. From all appearances, the reticulocytes matured within the circulation and were removed in about eight days. These results, the authors state, are to be accepted with caution in estimating the rate of red-cell regeneration and the life span of the normal erythrocyte.

Certain hemolytic mechanisms. Much is known of the fate of one of the red-cell constituents, hemoglobin, and of its conversion to bilirubin. Less knowledge exists, however, regarding the actual mechanisms by which the red cell itself is destroyed. It is not known whether it becomes swollen and bursts, is phagocytized by the ubiquitous reticulo-endothelial system and the spleen or simply breaks down and becomes fragmented through the innumerable buffetings it undoubtedly receives in its many passages through the circulation. Many theories have been proposed, but none have been completely confirmed. Although it is probable that the spleen makes red cells thicker during their more or less lengthy sojourns in that organ, it is not entirely clear that the organ is the graveyard of the red cell. A similar criticism holds for the reticulo-endothelial system, which many writers so glibly refer to as the site of red-cell destruction. Somehow, the chemical concepts dealing with lecithin and "lysolecithin" hemolysis are not highly convincing. It is possible that other simpler and more mechanical principles have to do with red-cell destruction. These may include erythrostatics in various organs, including the spleen, the effects of mechanical trauma and the inevitable ageing of the red cell.

Various mechanisms dealing with abnormal red-cell destruction, about which more is known, have

been cited in previous reviews. These include the effects of hemolysins, agglutinins, certain chemical factors and such physical factors as heat and mechanical trauma. Dameshek and Miller⁶⁸ demonstrated that red cells that are acted on by various types of agglutinins become more vulnerable to the effects of mechanical trauma than are normal erythrocytes — that is, their mechanical fragility is greatly increased. Stats and Wasserman⁶⁹ later showed that the cold hemagglutinin resulted in hemolysis when the cells were subjected to trauma. In further studies, Stats⁷⁰ states that no clear understanding of the role of mechanical trauma in normal or abnormal red-cell destruction is at hand. Shen, Castle and Fleming⁷¹ also studied the factor of mechanical fragility and have shown that an increased fragility occurs in the presence of agglutinins, in sickle-cell anemia and in certain cases of congenital hemolytic jaundice. They concluded that mechanical fragility is probably a factor in certain hemolytic processes.

Hereditary hemolytic anemias. Three types of hereditary hemolytic anemia may be discriminated — spherocytic (congenital hemolytic jaundice), Mediterranean target-oval cell (Cooley's anemia, Mediterranean anemia) and African target-sickle cell (sickle-cell anemia). The Mediterranean type, associated with leptocytosis — thin or target cells — has recently come to the fore as a type frequently seen in persons of Italian, Greek, Syrian and Portuguese ancestry. Dameshek⁷² has discriminated severe, moderate and mild types, the severe type having been known for years as Cooley's anemia. Despite the low color index, there is no response to iron therapy. Neel and Valentine⁷³ have made comprehensive studies of the disease in the rather large and homogeneous Italian population of Rochester, New York. They divide the condition into two types — thalassemia major and thalassemia minor. The major type occurred in 1 of 2368 births, the minor type was present in 1 of each 25 Italians tested. According to their figures, about 4 per cent of all Italians show hypochromic anemia or erythrocytosis, target or elliptical cells or both and increased hypotonic resistance of the red cells. Stippling of the red cells is a prominent feature and may lead to the incorrect diagnosis of lead poisoning in a patient who has been exposed to this metal. Many cases of Mediterranean anemia show more elliptocytosis than leptocytosis.

Target cells or leptocytes, which are unusually thin and are therefore unusually resistant to hypotonic salt solutions, are a prominent feature in both Mediterranean anemia and sickle-cell disease. Their presence in these conditions is probably indicative of an inherent fault in hemoglobin metabolism or perhaps the lack of an additional factor necessary for the complete synthesis of hemoglobin. Valentine and Neel⁷⁴ produced target cells in vitro by suspending normal erythrocytes in plasma or serum rendered hypertonic by evaporation or by the addi-

tion of sodium chloride or potassium oxalate. Furthermore, target cells from a case of sickle-cell disease were converted to normal-appearing red cells by suspending them in plasma rendered hypotonic. The significance of these observations is not entirely clear.

Sickle-cell anemia shows many target cells in the stained blood-smear preparations. This immediately brings up a possible relation between this disease and the Mediterranean syndrome. Many points of similarity are present, and forms intermediate between the two diseases are at times discriminated. Such a possible intermediate form may be that observed by Wagner⁷⁵ who found 86 per cent ovalocytes in a healthy Negro donor. No sickling was present. I have seen occasional target-cell and oval-cell cases in Negroes without sickling. The entire subject, particularly with reference to hereditary features, needs amplification. Scherer and Cecil⁷⁶ report a case of typical familial spherocytosis in a Negro. They state that this type of congenital hemolytic jaundice has been reported only once before in a Negro. As Negro blood becomes more and more diluted by intermarriage with other races, it is possible that the incidence of the spherocytic type will increase.

Cooley⁷⁷ described an anemia observed in two brothers of non-Mediterranean (Dutch) ancestry that appeared to be transmitted in a sex-linked manner similar to that of hemophilia. Striking elliptocytosis was present, in association with microcytosis, hypochromia, erythrocytosis and splenomegaly. The oral and intravenous administration of iron was without effect. Splenectomy was performed in one of the patients with only a partial response, although many of the elliptocytes disappeared. Cooley concludes that there is an inherent defect in hemoglobin synthesis unaffected by splenectomy.

A case of hemolytic anemia in infancy, possibly congenital or possibly acquired, is reported by David and Minot⁷⁸. During a hemolytic crisis the patient's serum showed the presence of an auto-hemolysin and an isohemolysin, which disappeared after splenectomy. The patient made a full recovery and behaved in most respects like most patients with acute hemolytic anemia of the acquired type. James and Evans⁷⁹ report a case of acquired hemolytic jaundice having its onset at the age of seventy and cured by splenectomy. Fourteen similar cases in patients aged fifty or over are discussed, five showed improvement after splenectomy. The risk of splenectomy in the elderly patient is naturally much higher than it is in the young one, acceptance of this risk is nevertheless essential if even one third of the patients are to be saved.

Hemolytic anemia that is secondary or symptomatic of a more fundamental disorder is occasionally seen. This occurs most frequently in Hodgkin's disease, lymphosarcoma and lymphatic leukemia, particularly when the spleen is greatly involved.

nant, and their cases would ordinarily have been classified as pernicious anemia of pregnancy. In all 3 cases, highly concentrated injectable liver extract was without effect, whereas large amounts of crude liver extract given orally were quite effective. Davis⁵⁹ reports somewhat similar observations in 3 cases of macrocytic anemia in children, proteolyzed liver given orally was rapidly effective. These observations are extended by Davis and Davidson⁶⁰ who successfully treated 15 apparently typical cases of pernicious anemia with oral proteolyzed liver after therapy with a parenteral liver extract preparation had proved unsuccessful. They conclude that proteolyzed — actually whole crude — liver contains a factor of hemopoietic value lacking in fractionated or concentrated liver extract. According to recent data, this unknown factor may be folic acid. The upshot of these several observations is that if one is reasonably certain that the macrocytic anemia in a given case is on a deficiency basis, therapy with either folic acid or crude liver extract should be used. Whether folic acid represents the entire answer to the therapy of pernicious anemia, and for that matter of all the deficiency states associated with macrocytic anemia, remains to be seen. This is particularly important with reference to the neurologic phenomena of pernicious anemia.

An important complication in pernicious anemia is the development of polyposis and gastric carcinoma. Polyps seem to form rather readily in the atrophied gastric mucosa of patients with the disease, and malignant degeneration of the polyps is fairly frequent. From a statistical study of 293 post-mortem cases of pernicious anemia, Kaplan and Rigler⁶¹ concluded that gastric carcinoma is three times as frequent in this group as in the general run of autopsied cases, the actual incidence being 12 per cent. It is suggested that frequent x-ray examination of the gastrointestinal tract be performed in cases of pernicious anemia.

The interesting pernicious anemia of pregnancy is discussed in an excellent and well documented article by Callender,⁶² based on a study of 25 cases. Excessive vomiting or diarrhea suggesting toxemia of pregnancy is frequent. The patient is not usually icteric, and changes in the tongue often occur. The blood picture is by no means typical, but the bone marrow usually shows the characteristic megaloblastic appearance of liver-extract deficiency. The gastric juice generally shows free hydrochloric acid. In addition to these atypical features, most patients are refractory to liver extract, and transfusions are often required. It is already indicated that folic acid will become the therapy of choice.

Hemolytic Anemias

Life span of the red cell. A number of articles dealing with the longevity of the red cell have appeared. Callender, Powell and Witts,⁶³ by the method of differential agglutination, determined that the average life span of the human erythro-

cyte is one hundred and twenty days — that is, that 0.83 per cent of the circulation is replaced daily. Harne, Lutz, Zimmerman and Davis⁶⁴ studied the life span of the red cells of monkeys by observing reticulocyte showers after hemorrhage and found it to be ninety-four to one hundred and seventeen days. Singer and Weisz⁶⁵ studied the same problem in the erythrocytes of dogs by observing the output of bile pigment in biliary fistulas of the renal type. By this method the average life span was found to be one hundred and ten days. In another article, Singer⁶⁶ reviews the various methods for determining the life span of the red cell and suggests that determination of this factor may be important in studying hemolytic anemia. By methods of cross determination — that is, by studying the survival time of normal red cells in the patient's circulation and that of his red cells in a normal circulation — it would be possible to demonstrate in a given hemolytic disorder whether the fundamental defect lay in the red cell itself or was extracellular.

The maturation of reticulocytes within the circulation was studied by Young and Lawrence,⁶⁷ who injected 150 cc of blood containing 73 per cent reticulocytes into a child with aplastic anemia. From all appearances, the reticulocytes matured within the circulation and were removed in about eight days. These results, the authors state, are to be accepted with caution in estimating the rate of red-cell regeneration and the life span of the normal erythrocyte.

Certain hemolytic mechanisms. Much is known of the fate of one of the red-cell constituents, hemoglobin, and of its conversion to bilirubin. Less knowledge exists, however, regarding the actual mechanisms by which the red cell itself is destroyed. It is not known whether it becomes swollen and bursts, is phagocytized by the ubiquitous reticulo-endothelial system and the spleen or simply breaks down and becomes fragmented through the innumerable buffetings it undoubtedly receives in its many passages through the circulation. Many theories have been proposed, but none have been completely confirmed. Although it is probable that the spleen makes red cells thicker during their more or less lengthy sojourns in that organ, it is not entirely clear that the organ is the graveyard of the red cell. A similar criticism holds for the reticulo-endothelial system, which many writers so glibly refer to as the site of red-cell destruction. Somehow, the chemical concepts dealing with lecithin and "lysolecithin" hemolysis are not highly convincing. It is possible that other simpler and more mechanical principles have to do with red-cell destruction. These may include erythrostatics in various organs, including the spleen, the effects of mechanical trauma and the inevitable ageing of the red cell.

Various mechanisms dealing with abnormal red-cell destruction, about which more is known, have

been cited in previous reviews. These include the effects of hemolysins, agglutinins, certain chemical factors and such physical factors as heat and mechanical trauma. Dameshek and Miller⁶⁵ demonstrated that red cells that are acted on by various types of agglutinins become more vulnerable to the effects of mechanical trauma than are normal erythrocytes—that is, their mechanical fragility is greatly increased. Stats and Wasserman⁶⁹ later showed that the cold hemagglutinin resulted in hemolysis when the cells were subjected to trauma. In further studies, Stats⁷⁰ states that no clear understanding of the role of mechanical trauma in normal or abnormal red-cell destruction is at hand. Shen, Castle and Fleming⁷¹ also studied the factor of mechanical fragility and have shown that an increased fragility occurs in the presence of agglutinins, in sickle-cell anemia and in certain cases of congenital hemolytic jaundice. They concluded that mechanical fragility is probably a factor in certain hemolytic processes.

Hereditary hemolytic anemias. Three types of hereditary hemolytic anemia may be discriminated—spherocytic (congenital hemolytic jaundice), Mediterranean target-oval cell (Cooley's anemia, Mediterranean anemia) and African target-sickle cell (sickle-cell anemia). The Mediterranean type, associated with leptocytosis—thin or target cells—has recently come to the fore as a type frequently seen in persons of Italian, Greek, Syrian and Portuguese ancestry. Dameshek⁷² has discriminated severe, moderate and mild types, the severe type having been known for years as Cooley's anemia. Despite the low color index, there is no response to iron therapy. Neel and Valentine⁷³ have made comprehensive studies of the disease in the rather large and homogeneous Italian population of Rochester, New York. They divide the condition into two types—thalassemia major and thalassemia minor. The major type occurred in 1 of 2368 births, the minor type was present in 1 of each 25 Italians tested. According to their figures, about 4 per cent of all Italians show hypochromic anemia or erythrocytosis, target or elliptical cells or both and increased hypotonic resistance of the red cells. Stuppling of the red cells is a prominent feature and may lead to the incorrect diagnosis of lead poisoning in a patient who has been exposed to this metal. Many cases of Mediterranean anemia show more elliptocytosis than leptocytosis.

Target cells or leptocytes, which are unusually thin and are therefore unusually resistant to hypotonic salt solutions, are a prominent feature in both Mediterranean anemia and sickle-cell disease. Their presence in these conditions is probably indicative of an inherent fault in hemoglobin metabolism or perhaps the lack of an additional factor necessary for the complete synthesis of hemoglobin. Valentine and Neel⁷⁴ produced target cells *in vitro* by suspending normal erythrocytes in plasma or serum rendered hypotonic by evaporation or by the addition

of sodium chloride or potassium oxalate. Furthermore, target cells from a case of sickle-cell disease were converted to normal-appearing red cells by suspending them in plasma rendered hypotonic. The significance of these observations is not entirely clear.

Sickle-cell anemia shows many target cells in the stained blood-smear preparations. This immediately brings up a possible relation between this disease and the Mediterranean syndrome. Many points of similarity are present, and forms intermediate between the two diseases are at times discriminated. Such a possible intermediate form may be that observed by Wagner⁷⁵ who found 86 per cent ovalocytes in a healthy Negro donor. No sickling was present. I have seen occasional target-cell and oval-cell cases in Negroes without sickling. The entire subject, particularly with reference to hereditary features, needs amplification. Scherer and Cecil⁷⁶ report a case of typical familial spherocytosis in a Negro. They state that this type of congenital hemolytic jaundice has been reported only once before in a Negro. As Negro blood becomes more and more diluted by intermarriage with other races, it is possible that the incidence of the spherocytic type will increase.

Cooley⁷⁷ described an anemia observed in two brothers of non-Mediterranean (Dutch) ancestry that appeared to be transmitted in a sex-linked manner similar to that of hemophilia. Striking elliptocytosis was present, in association with microcytosis, hypochromia, erythrocytosis and splenomegaly. The oral and intravenous administration of iron was without effect. Splenectomy was performed in one of the patients with only a partial response, although many of the elliptocytes disappeared. Cooley concludes that there is an inherent defect in hemoglobin synthesis unaffected by splenectomy.

A case of hemolytic anemia in infancy, possibly congenital or possibly acquired, is reported by David and Minot⁷⁸. During a hemolytic crisis the patient's serum showed the presence of an auto-hemolysin and an isohemolysin, which disappeared after splenectomy. The patient made a full recovery and behaved in most respects like most patients with acute hemolytic anemia of the acquired type. James and Evans⁷⁹ report a case of acquired hemolytic jaundice having its onset at the age of seventy and cured by splenectomy. Fourteen similar cases in patients aged fifty or over are discussed, five showed improvement after splenectomy. The risk of splenectomy in the elderly patient is naturally much higher than it is in the young one, acceptance of this risk is nevertheless essential if even one third of the patients are to be saved.

Hemolytic anemia that is secondary or symptomatic of a more fundamental disorder is occasionally seen. This occurs most frequently in Hodgkin's disease, lymphosarcoma and lymphatic leukemia, particularly when the spleen is greatly involved.

In rare cases a dermoid cyst, usually of the ovary, is associated with severe hemolytic anemia

CASE 32251

PRESENTATION OF CASE

A fifty-two-year-old widow entered the hospital for study of a lesion in the left upper lobe of the lung.

Six years before admission a panhysterectomy had been performed on the patient at another hospital for carcinoma of the fundus of the uterus. Pathological examination revealed a pedunculated papillary adenocarcinoma of the fundus, with minimal invasion of the myometrium. After operation she was observed frequently until two months before admission, with negative results, at this time she had a cold, with a productive cough during which one sputum sample was blood streaked. A circumscribed area of increased density, 2 cm in diameter, had appeared in the base of the left upper lobe of the lung. Tubercle bacilli could not be demonstrated in the sputum. The cough disappeared shortly, but the lesion in the lung remained. There were no further hemoptyses, and she was asymptomatic at the time of admission.

Between the ages of forty-one and fifty the patient had frequently been observed at a sanatorium following the death of her husband from tuberculosis. At first there was a small area of productive infiltration in the first right interspace, which gradually cleared during the period of study. No lesion was ever seen in the left lung. There was also a long history of moderately severe hypertension, with one episode of dyspnea and ankle swelling. She had several anginal attacks over a period of many years. Four years before admission a right pyelotomy for renal calculi was performed.

On physical examination the vagina was deep, and there was a well suspended vaginal cuff. The cervix and uterus were not palpable. The vaults were clear, and rectal examination was negative. The cardiac rhythm was irregular, and a blowing systolic murmur was heard at the apex. The lungs were clear.

The temperature was 98.6°F, the pulse 80, and the respirations 16. The blood pressure was 190 systolic, 115 diastolic.

There were 14 gm of hemoglobin. The white-cell count was 8000. A rounded area of increased density 2 cm in diameter was visible in the chest film just opposite the anterior end of the fourth left rib in the basal portion of the upper lobe (Figs 1 and 2). X-ray examination of the skull, pelvis and long bones was negative. In the intravenous pyelogram 58 per cent of the dye was excreted in sixty minutes. The right renal pelvis as seen by retrograde examination was reduplicated. The lowermost group of calyces was less blunted than those in the upper group. The superior calyces were represented only by large, somewhat irregular cavities. A distinct defect consistent with an aberrant vessel was seen between the somewhat widened upper ureter and the pelvis. The calyces on the left were normal, but the pelvis was large. The ureter was normal. Ten red cells and rare white cells per high-power field were found in the right kidney urine sediment, and occasional red cells and three white cells per high-power field in the left.

An operation was performed on the thirty-first hospital day.

DIFFERENTIAL DIAGNOSIS

DR RICHARD SCHATZKI "An operation was performed on the thirty-first hospital day." The record does not say what kind of operation, whether it was on the kidney or the lung, but I suppose that it was performed on the lung.

Apparently I have been given the task of answering the time-honored question of the cause of a round shadow in the lung. Before we come to that, let us analyze the rest of the patient's history. We know that she had hypertension and angina. I do not believe that these need concern us at all. She had lesions of her kidneys. We had better look at the pyelograms. The intravenous and retrograde examinations were performed in a two-week interval. The films demonstrate what the record says—that both kidneys function and both look abnormal, the right more than the left. On the right side the kidney pelvis is bifid. The lower part of the bifid pelvis shows the dilatation frequently seen with an aberrant vessel. At the ureteropelvic junction one can see a defect that fits that diagnosis. The upper part of the bifid pelvis is not dilated, but there are large sacs representing markedly dilated calyces. On the left side, the calyces are fairly normal. The kidney pelvis itself shows some dilatation, which is not too remarkable. The appearance of the right kidney is consistent with what one sees in an aberrant vessel with extensive infection in the upper half of the bifid pelvis. We can say that this patient had pyelonephritis in the upper half of the kidney. Could this be tuberculous pyelonephritis? Since the patient was exposed to tuberculosis, I think that it could be, but a few facts make it a little unlikely. The first is that a number of years

before admission she had a pyelotomy and stones were removed from that kidney. Tuberculosis would probably have been diagnosed at that time. In addition, the kidney condition on admission was asymptomatic. That does not rule out tuberculosis, but tuberculosis is less likely than nonspecific pyelonephritis.

Another pathologic condition was a round mass in her lung. The two x-ray examinations were done six weeks apart, and the shadow did not change. On the lateral view the lesion seems clearly to lie in the lower portion of the left upper lobe. The

heart to the left. The hilar shadows do not look abnormal, and they are in normal position and of normal size. There is one helpful fact in the history: the patient apparently had a negative chest film two years prior to entry. At least that is what the record states. For the sake of discussion we shall assume that the interpretation was correct, which would automatically exclude a number of congenital lesions, or some slowly growing lesions. In other words, there was a round mass, which developed in two years. This lesion was first discovered when the patient had a so-called "upper

FIGURE 1 X-Ray Film of Chest
The arrow points to a rounded area of increased density

shadow is not quite round in the only lateral view that we have here. In addition to this finding I see two more abnormalities, which are not described in the record and which indicate that there is a slight decrease in the size of the left lung somewhere. On the lateral view there are a few streaks in the region of the lingula of the left upper lobe, which are less distinct in the anteroposterior view. The right lung, which normally extends posteriorly to the region of the spinous process, extends almost to the left edge of the spine, indicating that the right lung is too large and the left lung too small. In addition there seems to be a slight shift of the

respiratory infection" and had some blood-streaked sputum. The slight decrease in the size of the lung could conceivably be the residue of atypical pneumonia, which she might have had at that time, and could be merely a red herring so far as the lung lesion is concerned. Could the patient have had an infarct two months previously, of which this was the residue? The round mass lies in the middle of the lobe and not against the pleural surface, which automatically excludes an infarct.

If one leaves out queer and unusual things, one is left with three possibilities: tuberculosis, metastatic cancer and primary cancer of the lung. This

patient had been exposed to tuberculosis. Tuberculosis can produce a round single lesion in the lung. More frequently in the primary phase, but also in the reinfection type of tuberculosis, single or multiple round lesions are seen. From a roentgenologic viewpoint this could be tuberculosis. The exposure was many years back, the patient had repeated examinations in between showing a negative chest film, and the location was rather unusual for primary

assume that this lesion was metastatic, we must forget what we said about the decrease in the size of the lung. I assume that had nothing to do with the present lesion, which could be a metastasis.

Could this woman have had a primary tumor of the lung, a bronchiogenic carcinoma? It would be just about the smallest I have seen, but that is because we probably have not heretofore operated on them at that stage of the game, whereas we now do,

FIGURE 2 X-Ray Film of Chest
The arrow points to a rounded area of increased density.

or reinfective type of tuberculosis, but still this may have been tuberculosis.

The patient had a carcinoma of the uterus removed six years before entry. Could this lesion in the lung be a metastasis? Cancer of the uterus may metastasize to the lung, and metastases may appear in the lung at such a late date, even though the primary tumor has been removed. How about the small hematemeses that the patient had? Can metastases produce bleeding? Yes, they can. Dr. King and Dr. Castleman* have published some cases of involvement of the bronchial tree by metastatic tumor causing hemorrhage. If we as-

suming to the marked development of chest surgery. In years past we should have enumerated the possibilities that we are talking about now and said, "Let us watch." This could be a very small primary carcinoma of the lung, more or less in the periphery.

I am ending up where I usually end up with a single round lesion in the lung. From purely roentgenologic evidence, it is often impossible to make a differential diagnosis. This picture could be explained by any of the three possibilities that I have mentioned. That is my answer as a roentgenologist. As a clinician, I should probably take a guess, and I shall say that it was a malignant tumor.

DR. EDWARD B. BENEDICT: Would you consider a metastasis from a kidney tumor?

*King, D. S. and Castleman, B. "Bronchial involvement in metastatic pulmonary malignancy." *J. Thoracic Surg.* 4:305-315, 1943.

before admission she had a pyelotomy and stones were removed from that kidney. Tuberculosis would probably have been diagnosed at that time. In addition, the kidney condition on admission was asymptomatic. That does not rule out tuberculosis, but tuberculosis is less likely than nonspecific pyelonephritis.

Another pathologic condition was a round mass in her lung. The two x-ray examinations were done six weeks apart, and the shadow did not change. On the lateral view the lesion seems clearly to lie in the lower portion of the left upper lobe. The

heart to the left. The hilar shadows do not look abnormal, and they are in normal position and of normal size. There is one helpful fact in the history: the patient apparently had a negative chest film two years prior to entry. At least that is what the record states. For the sake of discussion we shall assume that the interpretation was correct, which would automatically exclude a number of congenital lesions, or some slowly growing lesions. In other words, there was a round mass, which developed in two years. This lesion was first discovered when the patient had a so-called "upper

shadow is not quite round in the only lateral view that we have here. In addition to this finding I see two more abnormalities, which are not described in the record and which indicate that there is a slight decrease in the size of the left lung somewhere. On the lateral view there are a few streaks in the region of the lingula of the left upper lobe, which are less distinct in the anteroposterior view. The right lung, which normally extends posteriorly to the region of the spinous process, extends almost to the left edge of the spine, indicating that the right lung is too large and the left lung too small. In addition there seems to be a slight shift of the

respiratory infection" and had some blood-streaked sputum. The slight decrease in the size of the lung could conceivably be the residue of atypical pneumonia, which she might have had at that time, and could be merely a red herring so far as the lung lesion is concerned. Could the patient have had an infarct two months previously, of which this was the residue? The round mass lies in the middle of the lobe and not against the pleural surface, which automatically excludes an infarct.

If one leaves out queer and unusual things, one is left with three possibilities: tuberculosis, metastatic cancer and primary cancer of the lung. This

basis, we are on safe grounds in assuming that it was a metastasis from the uterus, which had been resected seven years previously.

CASE 32252

PRESENTATION OF CASE

A thirty-two-year-old housewife entered the hospital for study of a mass in the right lung.

One and a half years before admission the patient entered another hospital because of headache and weight loss. An area of density 3.0 by 2.5 cm was visible by x-ray in the right lower lobe. It was smooth in outline and homogeneous in density. The lung fields were otherwise clear. There had been no cough or hemoptysis. Bronchoscopy was negative. The patient refused operation and was discharged. During the next year and a half she was constantly fatigued, but lost no more weight. The headaches became less frequent and severer. The attacks were often associated with dizziness and mild nausea. Mild exertional dyspnea appeared in the last six months. One month before admission a mild hacking, nonproductive cough developed. There was no fever or sweating at night.

With the birth of a son thirteen years prior to admission, the patient had had "milk legs," which kept her in bed nine weeks. Early in this period there was a sudden sharp, pleuritic pain anteriorly in the left chest. This lasted a day and caused difficulty in breathing.

A cousin with whom the patient had close contact died of tuberculosis eight years before admission. At the age of twenty-four the patient had a bilateral salpingectomy. The pathological report was acute bilateral salpingitis. The periods thereafter were regular until admission, lasting from one to six days. The first day of the period was usually accompanied by cramping pains.

On physical examination there was a decrease in breath and spoken voice sounds over an area 4 cm in diameter to the right of the spine over the right lower lobe. The heart was normal. There was a healed midline suprapubic scar, with an area of slight tenderness around it. The cervix was long and normal. The uterus was forward and attached to the abdominal wall, was larger than normal and felt round. A hard, firm, irregular mass was palpated along the right side of the fundus.

The temperature was 99°F, the pulse 72, and the respirations 20. The blood pressure was 110 systolic, 70 diastolic.

The red-cell count was 4,180,000 with 12.7 gm of hemoglobin. The white-cell count was 7700, with 57 per cent neutrophils. The urine was normal. A x-ray examination of the lung revealed a mass just below the right hilum, probably in the right lower lobe. It had not changed in appearance from the original film. A flat plate of the abdomen and an

intravenous pyelogram showed normal urinary tracts. There was an ill defined, irregular mass in the pelvis slightly more to the right than left measuring approximately 11 x 6 cm in diameter. It did not appear to exert any pressure on the urinary tract. A barium enema was negative.

An operation was performed on the twelfth hospital day.

DIFFERENTIAL DIAGNOSIS

DR DONALD S. KING: As Dr. Schatzki said in the preceding case, we are constantly faced with the problem of what to do with cases that show in the x-ray film, a small rounded area of density in the lung field. Within the last three weeks we have seen such shadows in 3 cases, similar to the one that is presented to me today. I should like to put up the films on these 3 cases along with the film of the case that I am to discuss. The first film is the film of today's case. Unfortunately there is only a Buckle film, which does not give the same density as an ordinary film. The lateral film in this case is also shown. As one notes the 3 other cases are different from the case under discussion in that the lesions are in the peripheral areas of the lungs and are not near the hilum. The first of the outside patients had a negative x-ray film in 1939. An x-ray film taken in 1942 showed the rounded lesion. Fortunately I was away at the time that this film was taken and did not have to decide whether anything should be done about it. We have other films taken in 1944 and 1946, which show that the lesion had changed very little if at all. The second case was one in which the lesion was picked up by routine examination of all the employees of one of the large Boston department stores; there were no symptoms of pulmonary disease. In the third case there were definite pulmonary symptoms, and the decision to operate will probably not be difficult.

In the discussion of today's case we note first the story of pleuritic pain that lasted a day and caused difficulty in breathing. There seems little question that the symptoms were due to a pulmonary infarct. I do not believe that there is any association between this episode and the rounded shadow that appeared some years later.

As in the case discussed by Dr. Schatzki, this patient was also exposed to tuberculosis, and the diagnosis of tuberculosis must therefore be considered. There is a possibility that the bilateral salpingitis was also of a tuberculous nature but I assume that a pathological report of acute salpingitis rules out tuberculosis. Am I right in this, Dr. Meigs?

DR JOE V. MEIGS: Yes.

DR KING: "There was a decrease in breath and spoken voice sounds over an area 4 cm in diameter to the right of the spine." This examiner certainly made a careful examination. I shall wager anything that he had seen the x-ray films before he made that report.

DR SCHATZKI I should consider metastases from any tumor. We have the old one, adenocarcinoma of the uterus. I do not see a primary tumor of the kidneys in the films.

DR JOE V MEIGS Is it not unusual for a patient with carcinoma of the endometrium, a papillary type, without much invasion of the myometrium, to have metastases six years later? Most patients who have that sort of cancer do not have recurrences and metastases.

DR DONALD S KING I hope it is not cancer because if it is we must do a great deal of operating. It may be cancer and I should not want to be the one to say it is not. The case that I have to discuss in a moment is something of the same problem, and I brought down slides on 3 other cases that are waiting for a decision on this type of shadow. These 2 cases this morning will help us in making our decision. I shall guess that the diagnosis in this case is tuberculosis.

DR F DENNETTE ADAMS What about bronchoscopy?

DR TRACY B MALLORY The lesion was so far out in the periphery that it was not helpful. I do not know whether Dr Benedict expressed an opinion about this beforehand.

DR BENEDICT We were of the opinion that it would not show anything.

DR NICHOLAS MARTIN What about the possibility of adenoma of the bronchus?

DR SCHATZKI I do not believe that we have had a single benign adenoma of the lung that has not produced fairly marked bronchial occlusion.

DR MARTIN I disagree — not absolutely, but I think it does occur.

DR RICHARD H SWEET Before we discuss it any further might we not ask this question: Is it not true that adenomas are related to the large bronchi?

DR MARTIN Yes.

DR SWEET We have had one benign adenoma that was not in a large bronchus.

DR MARTIN I still think we have to list it as a possibility.

DR SCHATZKI Would not the negative x-ray examination two years previously be against benign adenoma?

DR MARTIN Yes, that is a better reason.

DR SWEET Dr Schatzki and Dr King brought up what I consider an important point, namely, the utilization of surgery in some of these cases to make a diagnosis as well as to carry out treatment, because thoracic surgery is now on such a sound basis that we can operate in cases of this sort with a negligible risk. In recent years we have explored many of these patients whom, as Dr Schatzki said, we used to watch. Our preliminary diagnosis was tumor, probably metastatic. I was impressed, as Dr King and Dr Schatzki were, by the fact that if it was a primary carcinoma, it was certainly a very small one, smaller than any that I can recollect.

There was another factor that made the case interesting — the patient entered with the complaint of hypertension. Dr Smithwick was asked to see her about the possibility of treating the hypertension surgically. The question arose whether she might have the first stage of sympathectomy done at the same time as the lung operation. That was the question put to me. I did not see her until late in the course of the study. I was opposed to combining the two procedures because I believed that the tumor in the lung was of greater importance to this patient from the standpoint of length of life than the hypertension. I agreed that, if it turned out to be a simple procedure, we might do a thoracic exploration. We explored her and found an anomalous upper lobe. The peculiarities that Dr Schatzki mentioned are explained, I think, on an anatomical basis, because she had a lingula with an almost complete fissure. That fissure was subdivided to correspond to the two branches of the lingular bronchus. It was a peculiar looking lingula. At the base of the proximal portion of one of the lingular segments was a tumor, which was obviously neoplastic. We thought first of doing a lingulectomy, but it was so close to where I had to resect that I decided that the safer and more conservative procedure was to do a left upper lobectomy. Because it was a simple operation, I allowed Dr Scannell, after I had completed the lobectomy, to do a sympathectomy, which he did, and the patient made an excellent recovery.

CLINICAL DIAGNOSIS

Tumor of lung, probably metastatic

DR SCHATZKI'S DIAGNOSIS

Malignant tumor of lung

ANATOMICAL DIAGNOSIS

Pulmonary metastasis from adenoacanthoma of uterus

PATHOLOGICAL DISCUSSION

DR MALLORY The crux of the diagnosis rests on the histologic examination of this tumor. It was quite small, 2 cm in diameter, and very well circumscribed. A small bronchus ran into and terminated in the tumor, and the mucosa of this bronchus was slightly roughened by invasive tumor at the point of contact. On microscopical examination the tumor proved to be an adenocarcinoma, with a number of foci of squamous-cell metaplasia, the type of tumor ordinarily called an adenoacanthoma. This is a relatively frequent type of tumor in the uterus, much less usual in any other organ, and I cannot remember ever having seen it as a form of primary bronchiogenic carcinoma. We were eventually able to borrow a slide of the original uterine tumor and found that it also had the characteristic appearance of an adenoacanthoma. On that

basis, we are on safe grounds in assuming that it was a metastasis from the uterus, which had been resected seven years previously

CASE 32252

PRESENTATION OF CASE

A thirty-two-year-old housewife entered the hospital for study of a mass in the right lung

One and a half years before admission the patient entered another hospital because of headache and weight loss. An area of density 3.0 by 2.5 cm was visible by x-ray in the right lower lobe. It was smooth in outline and homogeneous in density. The lung fields were otherwise clear. There had been no cough or hemoptysis. Bronchoscopy was negative. The patient refused operation and was discharged. During the next year and a half she was constantly fatigued, but lost no more weight. The headaches became less frequent and severer. The attacks were often associated with dizziness and mild nausea. Mild exertional dyspnea appeared in the last six months. One month before admission a mild hacking, nonproductive cough developed. There was no fever or sweating at night.

With the birth of a son thirteen years prior to admission, the patient had had "milk legs," which kept her in bed nine weeks. Early in this period there was a sudden, sharp, pleuritic pain anteriorly in the left chest. This lasted a day and caused difficulty in breathing.

A cousin with whom the patient had close contact died of tuberculosis eight years before admission. At the age of twenty-four the patient had a bilateral salpingectomy. The pathological report was acute bilateral salpingitis. The periods thereafter were regular until admission, lasting from one to six days. The first day of the period was usually accompanied by cramping pains.

On physical examination there was a decrease in breath and spoken voice sounds over an area 4 cm in diameter to the right of the spine over the right lower lobe. The heart was normal. There was a lower lobe. The heart was normal. There was a healed midline suprapubic scar, with an area of slight tenderness around it. The cervix was long and normal. The uterus was forward and attached to the abdominal wall, was larger than normal and felt round. A hard, firm, irregular mass was palpated along the right side of the fundus.

The temperature was 99°F, the pulse 72, and the respirations 20. The blood pressure was 110 systolic, 70 diastolic.

The red-cell count was 4,180,000 with 12.7 gm of hemoglobin. The white-cell count was 7700, with 57 per cent neutrophils. The urine was normal. X-ray examination of the lung revealed a mass just below the right hilum, probably in the right lower lobe. It had not changed in appearance from the original film. A flat plate of the abdomen and an

intravenous pyelogram showed normal urinary tracts. There was an ill defined, irregular mass in the pelvis slightly more to the right than left measuring approximately 11 x 6 cm in diameter. It did not appear to exert any pressure on the urinary tract. A barium enema was negative.

An operation was performed on the twelfth hospital day.

DIFFERENTIAL DIAGNOSIS

DR DONALD S. KING: As Dr. Schatzki said in the preceding case, we are constantly faced with the problem of what to do with cases that show, in the x-ray film, a small rounded area of density in the lung field. Within the last three weeks we have seen such shadows in 3 cases, similar to the one that is presented to me today. I should like to put up the films on these 3 cases along with the film of the case that I am to discuss. The first film is the film of today's case. Unfortunately there is only a Bucky film, which does not give the same density as an ordinary film. The lateral film in this case is also shown. As one notes, the 3 other cases are different from the case under discussion in that the lesions are in the peripheral areas of the lungs and are not near the hilum. The first of the outside patients had a negative x-ray film in 1939. An x-ray film taken in 1942 showed the rounded lesion. Fortunately I was away at the time that this film was taken and did not have to decide whether anything should be done about it. We have other films taken in 1944 and 1946, which show that the lesion had changed very little if at all. The second case was one in which the lesion was picked up by routine examination of all the employees of one of the large Boston department stores; there were no symptoms of pulmonary disease. In the third case there were definite pulmonary symptoms, and the decision to operate will probably not be difficult.

In the discussion of today's case we note first the story of pleuritic pain that lasted a day and caused difficulty in breathing. There seems little question that the symptoms were due to a pulmonary infarct. I do not believe that there is any association between this episode and the rounded shadow that appeared some years later.

As in the case discussed by Dr. Schatzki, this patient was also exposed to tuberculosis, and the diagnosis of tuberculosis must therefore be considered. There is a possibility that the bilateral salpingitis was also of a tuberculous nature, but I assume that a pathological report of acute salpingitis rules out tuberculosis. Am I right in this, Dr. Meigs?

DR JOE V. MEIGS: Yes.

DR KING: "There was a decrease in breath and spoken voice sounds over an area 4 cm in diameter to the right of the spine." This examiner certainly made a careful examination. I shall wager anything that he had seen the x-ray films before he made that report.

I assume, from the description of the pelvic examination, that there were two masses, one of which was the uterus itself and the other outside the uterus, but I cannot be absolutely sure of this from the description given

The most important sentence in the whole history of the case is in the x-ray report, which reads, "It had not changed in appearance from the original film." We are therefore dealing with an x-ray lesion that did not change in one and a half years. The X-ray Department goes on to report, "An intravenous pyelogram showed normal urinary tracts." Obviously the doctors in charge of the case were looking for evidence of a hypernephroma from which there had been a solitary metastasis to the lung.

I suppose again, as in Dr Schatzki's case, that the operation performed was an operation on the lung and not on the pelvis, and that we are again faced with the question of the nature of the round shadow. My first inclination was to bet again on tuberculosis because of the story of exposure and because the symptoms were somewhat suggestive of a tuberculous infection. But there are two things against this diagnosis. In the first place, with a small rounded shadow that is due to tuberculosis, there is usually evidence of tuberculosis elsewhere in the lungs. This is, however, not necessarily true. In the second place, except in a calcified primary complex, the rounded shadows due to tuberculosis, or so-called "tuberculoma," usually change in appearance in eighteen months' time. I believe that almost all the tuberculomas that we have observed have changed in the x-ray film in this length of time. Am I right, Dr Sweet?

DR RICHARD H SWEET Yes, I agree.

DR KING I am therefore inclined to say that the lesion under discussion is not tuberculosis.

As I noted in the beginning, this rounded shadow is near the hilum of the lung where we have seen some bronchiogenic cysts, and some of the smaller cysts in this area have given somewhat similar x-ray appearance. Usually, however, the area of density is larger and gives a somewhat different shadow. I do not believe that this picture is sufficiently characteristic of a bronchiogenic cyst to warrant such a diagnosis.

Primary carcinoma of the bronchus and metastatic cancer are both, I believe, ruled out by the fact that there was no change in the appearance of the x-ray film in a year and a half. So far as our experience goes I do not believe that there has been a single case of primary or metastatic cancer of the lung in which the x-ray shadow has not changed in this length of time. Even the hypernephromas, some of which are very slow growing, have changed definitely in that time.

Of course I am concerned about the condition in the pelvis. As I went over the case I was about to forget that there was anything wrong there, and until the discussion of Dr Schatzki's case I had not

given a thought to the possibility of a pulmonary metastasis from the pelvis. Assuming that the operation was on the lung, it is quite obvious that the doctors in charge did not believe that there was pelvic cancer from which a metastasis might occur. But I should like to have Dr Meigs discuss the possible diagnoses of the pelvic mass.

DR TRACY B MALLORY You are wrong about that. The operation was on the pelvis.

DR KING This is, of course, a bombshell. I was going to forget the pelvic disease so I am even more interested in what you think about the pelvis condition, Dr Meigs.

DR MEIGS I have a note on the record that I shall try to find.

DR FLETCHER H COLBY I am not convinced that metastatic lesions in the lungs necessarily change, as you say, in a brief period. I do not know about one and half years.

DR KING The only ones that I can be sure about are the ones that I have followed personally, and as I said, all of these have increased in size in a few months. In the famous case of hypernephroma^{1, 2} in which the kidney was first removed and the metastasis taken out several months later, with apparent cure after twelve years, the metastatic lesion had almost doubled in size in a year's time. We have also recently followed a case in the Baker Memorial Hospital in which the hypernephroma was taken out five years ago and metastatic lesions appeared in the lung one year ago. The lesions in the lung have unmistakably increased in size during the year's observation. What the chest x-ray films might have shown if they had been taken in the four-year period before the metastatic lesions were discovered, I do not know.

DR COLBY Some are fairly slow in growing. They must be, because secondary deposits may appear even as late as fifteen years or more.

DR KING I am going on the basis of my own experience in tumors like this.

DR MEIGS I shall read part of my note. "The cervix is long and normal in appearance. The uterus is forward and attached to the abdominal wall, it is large and round—definitely larger than it should be. The left side is negative, but in the right side I believe I feel a hard, firm, irregular mass. This mass probably represents the right ovary, although with tumor in the lung I think we ought to consider that that might be a question of neoplasm. Dr Benedict should be asked if he would like to peritoneoscope her. If he does not, and all studies on your Service are negative, we would be very glad to explore her."

The question is, What kind of mass is it? Apparently she had no abnormal menstrual periods. One would have to consider the possibility of a fibroid growing off the side of the uterus. It might be in the form of leiomyosarcoma, which is a malignant tumor and may metastasize to the lung. Pelvic

inflammatory disease we rule out because she had had both tubes removed. One would have to consider ovarian tumor, and it could even be endometrial cancer.

DR. KING: I should not have Dr. Meigs do my work for me, but I think it is fair under the circumstances.

We do not know what this lesion in the lung was then?

DR. MALLORY: Yes, we do.

DR. KING: And you know what the pelvis showed too?

DR. MALLORY: Yes.

DR. KING: I am now faced with the question of whether we can connect the two processes. I came determined not to consider the pelvis as a possible source of metastasis, and I shall keep to that line of approach. I do not believe that this is metastatic cancer, and I have already discarded tuberculosis and bronchiogenic cyst. The question that was raised about benign adenoma in the previous case interests me a great deal. Until 1942, except for one possible case, all the adenomas that we had followed were at least in part in the lumina of the larger bronchi and could be definitely proved by bronchoscopic biopsy. I had been told that while I was away there was a case admitted from another hospital in which operation had shown an adenoma that was entirely outside the bronchus. The case under discussion may be that case. I do not know. In view of the fact that this lesion has not changed in x-ray appearance in a year and a half and that it is close to the large bronchi, adenoma must be considered as a possible diagnosis.

There are a multitude of other benign tumors that should be mentioned, but it would be pure guesswork to try to name any other tumor. Fibroma, chondroma and hamartoma are all possible, but taking everything into consideration since I have to commit myself as to diagnosis I should say adenoma.

CLINICAL DIAGNOSIS

Adenoma of bronchus

DR. KING'S DIAGNOSIS

Benign adenoma of lung

ANATOMICAL DIAGNOSES

Adenoma of bronchus

Endometriosis of ovary

PATHOLOGICAL DISCUSSION

DR. MALLORY: The first operation was on the pelvis, and an ovarian mass was found to be due to

extensive endometriosis of the ovary. About ten days later the chest was explored, and Dr. Sweet will now tell about that.

DR. SWEET: This patient was admitted on the gynecological service, and I was asked to see her before the pelvic operation relative to what was wrong in the chest and whether anything should be done. I thought we had better see what was in the pelvis first because at that time we did give some thought to metastatic tumor. Having proved that the pelvic tumor was benign and therefore not responsible for the pulmonary lesion, we did go ahead with the chest operation. My reasoning was exactly the same as Dr. King's, and I came to the same conclusion on the same premise—that it was an adenoma. It was an interesting operation because when I first exposed the tumor it was in the lower lobe, presenting on the fissure as it lay against the middle lobe. I thought that I could excise the tumor locally. There was not much lung tissue over it. I believed that it was something I could pry out without difficulty, but in dissecting I saw that it was actually growing out of a bronchus and did a lobectomy. The further pathologic details we shall hear from Dr. Mallory, but I was convinced at the time that I was taking out an adenoma.

DR. KING: Was it inside or outside?

DR. SWEET: Both.

DR. MALLORY: I have the gross picture of the resected specimen. You can see the tumor without any difficulty, almost completely circumscribed, but as Dr. Sweet explained it was definitely adherent to the outer portion of the bronchial wall. There was no involvement of the bronchial mucosa and no narrowing of the bronchus by tumor. These tumors ordinarily arise within the bronchus, although they may also extend outward between the cartilages and form a dumbbell-shaped mass. This is a unique case, in our series at any rate, in that the tumor lay entirely outside the bronchus, with no projection in the bronchial lumen.

DR. MEIGS: This patient had bilateral salpingitis and endometritis eight years before admission. It is rare to see endometriosis under such conditions when the tubes are closed. This seems to refute Sampson's theory of menstrual blood flowing back through the tubes and producing endometriosis. If she had had the condition when she was first operated on it would probably have been noted.

DR. MALLORY: You might have noted it, but most surgeons do not see it as readily as you do.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Feoway, Boston 15, Massachusetts.

TO THE MEMORY OF WALTER B. CANNON

ELSEWHERE in this issue of the *Journal* is a description of the Walter B. Cannon Memorial Hospital Fund. It is the purpose of this editorial to draw attention to this enterprise, and to point out how near the work to which this fund is to be devoted was to Dr. Cannon's heart.

For a number of years Spanish students worked intimately with Dr. Cannon in his laboratory, and when the lamentable overthrow of liberalism occurred in Spain, their continuing relation was greatly curtailed. Dr. Cannon had an instinctive, almost puritanical justice in his make-up, which overflowed with especial forcefulness when intellectual freedom suffered, particularly when the sufferers were imaginative young men.

If life had been spared him, Dr. Cannon would have worked ceaselessly for the Spanish outcasts in France, and he would have been sympathetic towards aiding a hospital to lighten their misery. He was always intimately involved with actual medicine and surgery, and for years the staff of the Peter Bent Brigham Hospital felt his close interest in their problems. Moreover, throughout World War I all his efforts while he was in France and England were directed toward solution of the clinical problems represented by surgical shock and hemorrhage. In World War II his interests continued in the same direction and were coupled with efforts to promote more intimate relations between productive scholars in different countries.

The memorial is finely appropriate to the man and he in his turn would have been particularly happy that this just and merciful monument in his name is, at least in part, the gift of medical friends and colleagues. Many will remember how touched he was on the occasion of his twenty-fifth year as George Higginson Professor of Physiology, Harvard Medical School, that the funds for the celebration were subscribed in small amounts from several hundred former students and associates, and not in large contributions from a few. It is to be hoped that men and women in medicine will respond to this appeal by giving what they can. Good wishes mean much, but a good wish with a single dollar behind it can mean much more!

THE CARE OF THE PATIENT

WE have become accustomed, in recent years, to think of the care of the patient from an economic and sociologic point of view — to fall in line with the theory, not now so startling as it once was, that the inhabitants of the earth should share more freely than was once the case in the fruits of their earth and in the benefits of human progress. From the tradition cherished at one time that the patient was a sort of bond servant of his practitioner, because of his own choice, we are gradually coming to entertain the idea that reasonably good medical care should be available, at least to most of us, at a price commensurate with our ability to pay, and that that cost, in fairness to the profession supply-

ing the service, should be spread over the whole population or certain segments of it

Thus have come into being prepaid hospital-insurance plans, group practice as applied to industries, respectable coalitions of physicians to furnish medical service at a reasonable cost, as exemplified by the Blue Shield of the Massachusetts Medical Society, and, finally, impending federal

control of certain types or parts of practice. This does not necessarily spell the doom of all private practice as we have known it, with its inadequacies and its inequalities both as to cost and as to quality, but it does mean that a social revolution is on the high road, and we might as well ride with it.

Many of these things will come to pass well or ill, wisely or unwisely, according to the will of

the people and the ability of their representatives to plan, and since we cannot block them we had best try and direct them. What concerns us even more closely, because it is our medical skill that provides it, is the caliber of care that our fellow men receive from us. This we must not lose sight of when we are arguing over costs because we, and not the patient, know best the quality of our goods.

It is, of course, a truism to say that medical knowledge and the treatment and prevention of disease, which are the aims of medical knowledge, are making rapid advances. They have been making rapid advances since the authority of Galen was thrown off. What is important to recognize is that the art of medicine, valuable as it is, is becoming more and more simply an adjunct of the science. More and more the study and the treatment of the sick are being taken away from the home and the office and brought into the hospital and its contiguous laboratory.

Less and less is the practitioner — and this is no reflection on him — able alone to carry out the

studies and institute the treatments that his patients may require. Hospital facilities must be available to him, but whether or not he is on the staff, those facilities are usually inadequate unless they include trained professional personnel — in the operating rooms, in the x-ray department, in the laboratory and on the ward.

Much of the best medical care now depends on

teamwork, — this is the real revolution in medicine, — and this often implies the best hospital care in every sense of the word. One of the crying needs of medical practice today, so far as the technical care of the patient is concerned, is not simply to have a hospital to which the practitioner can take his patient and there care for him but rather to have a hospital to which he can take him and, if

necessary, leave him to the care of those qualified in the details of modern medical procedures.

MASSACHUSETTS MEDICAL SOCIETY POSTWAR LOAN FUND

The Postwar Loan Fund has been set up, and all discharged medical officers who were members of the Massachusetts Medical Society in good standing at the time of their entry into the service may apply for loans from this fund. For further information apply to

MASSACHUSETTS MEDICAL SOCIETY DEATHS

ELLIS — Edward K. Ellis, M.D., of Needham, died June 7. He was in his sixty-seventh year.

Dr. Ellis received his degree from Tufts College Medical School in 1902. He was a member of the New England Ophthalmological Society and a fellow of the American Medical Association.

His widow survives.

OVERLANDER — J. Eliot Overlander, M.D., of Springfield, died May 26. He was in his sixty-sixth year.

Dr. Overlander received his degree from Harvard Medical School in 1909. He was formerly senior medical officer of the Springfield Hospital. He was a fellow of the American Medical Association.

His widow survives.

QUEST — James F. Quest, M.D., of Boston, died May 27. He was in his sixty-eighth year.

Dr. Quest received his degree from the University of Vermont College of Medicine in 1906. He was a fellow of the American Medical Association.

TREANOR — John P. Treanor, M.D., of Dorchester, died May 4. He was in his eighty-second year.

Dr. Treanor received his degree from Harvard Medical School in 1895. He was a member of the New England Pediatric Society and a fellow of the American Medical Association.

His widow survives.

MISCELLANY

DR WALTER B CANNON MEMORIAL
HOSPITAL FUND

A memorial to Dr Walter B Cannon, late George Higginson Professor of Physiology at Harvard Medical School, is to be established in Toulouse, France. A hospital there, organized and staffed by Spanish refugees in France to serve their fellow refugees, is to be expanded and operated under its new name, the Dr Walter B Cannon Memorial Hospital.

Dr Cannon, who was president of the American Association for the Advancement of Science in 1939, actively aided the Spanish Republicans from the start of the Civil War in 1936 to the end of his life. He became chairman of the Medical Bureau to Aid Spanish Democracy in 1937 and at his death was honorary co-chairman, Boston Chapter, Joint Anti-Fascist Refugee Committee. Through the Unitarian Service Committee, the Joint Anti-Fascist Refugee Committee has been helping 150,000 Spanish refugees remaining in France after three years of war and seven years of destitution and suffering. Ineligible for aid from the Red Cross, UNRRA or the French Government, these people without a country are as acutely in need of medical care as almost anyone in the world. They depend entirely on American charity.

About one hundred and fifty prominent Boston citizens have just started a drive for \$75,000 to buy some of the necessary equipment for the hospital in Toulouse and to safeguard its continued operation. All funds are managed and spent in France by the Unitarian Service Committee. After Spain returns to democracy, the memorial to Dr Cannon will be perpetuated there.

Co-chairmen of the drive are Dr George R. Minot, professor of medicine, Harvard Medical School, Dr Frederick May Eliot, president, American Unitarian Association, Ralph Barton Perry, professor of philosophy, Harvard University, and Paul T. Smith, attorney. Among the medical sponsors are Drs Donald G. Anderson, Joseph C. Aub, Herrman L. Blumgart, Arlie V. Bock, Ethan Allan Brown, Allan M. Butler, William B. Castle, David Cheever, Stanley Cobb, Edwin J. Cohn, Hilbert F. Day, Robert L. DeNormandie, Cecil K. Drinker, John T. Edsall, Laurence B. Ellis, James M. Faulkner, Jacob Fine, Alexander Forbes, Channing Frothingham, James L. Gamble, Bernard I. Goldberg, Charles A. Janeway, Chester S. Keefer, Mary R. Lakeman, Eugene M. Landis, Samuel A. Levine, Moses H. Lurie, Helen I. D. McGillicuddy, J. H. Means, Leroy M. S. Miner, Dwight O'Hara, Marian C. Putnam, David Rapoport, George C. Shattuck, Richard M. Smith, Paul D. White, George B. Wislocki and S. Ruth Wolbach.

Headquarters of the Dr Walter B. Cannon Memorial Hospital Fund are at 14 Beacon Street, Boston.

CORRESPONDENCE

FIRST USE OF X-RAYS IN BOSTON

To the Editor The letter in the May 16 issue of the *Journal* on the first use of x-rays in Boston reminded me of an incident. As a student I sat in the staff chairs of the old amphitheater at the Massachusetts General Hospital waiting for Dr Warren's lecture and reading the *Boston Post*, in which there was a short item mentioning that a Doctor Roentgen, of Vienna, had discovered a method of photographing the bones through the flesh. I circled it with a blue pencil and passed it to Dr Warren when he came in. He read it and smiled, remarking, "That is a good newspaper story, isn't it, young man?" Before many months Dr Warren was having his own cases x-rayed. I never got a chance to remind him of his remark.

Walter Dodd, who was the Massachusetts General Hospital pharmacist and who was interested in photography, took many pictures of pathological specimens. Being a snapshot amateur, I was interested in his work. In fear and trembling I got a picture of the dissecting room in the Boylston Street Medical School, and was caught by good old Tom Bonney, but gave him a print to placate him. Fond memories.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Periodontal Diseases and Soft Tissue Lesions of the Oral Cavity: Diagnosis and treatment. By Arthur H. Merrett, D.D.S., Sc.D. Third edition. 8°, cloth, 256 pp., with 53 illustrations. New York: Macmillan Company, 1945. \$3.50.

† The previous editions of this monograph contained only the text on periodontal diseases. In this third edition a second part, comprising six chapters on soft-tissue lesions of the mouth, has been added. The author's approach is clinical, and the original text has been revised and brought up to date.

A Textbook of Ophthalmology. By Sanford R. Gifford, M.D. 12°, cloth, 457 pp., with 215 illustrations, 4 charts and 13 plates. Philadelphia: W. B. Saunders Company, 1945. \$4.00.

Dr Gifford before his death completed the revision of the third edition of his small textbook first published in 1938. The text has been brought up to date, and new material has been added on ptosis, contact glasses, cyclodiathermy and keratoconjunctivitis. New illustrations in black and white have been incorporated in the text. Also twelve full page color plates are used to delineate common diseased conditions of the eyes. The objective of the author, formerly professor at Northwestern University, was to compress into a small volume for medical students and general practitioners the essentials of modern ophthalmology. The need for three editions of his book speaks well for the attainment of his purpose.

DISPUTED INDICATIONS AND TECHNICS FOR CESAREAN SECTION*

EDWARD G. WATERS, M.D.†

JERSEY CITY, NEW JERSEY

WITH cesarean section, opinion on indications and choice of operation should certainly approach unanimity. So much has been written and so many formidable analytic compilations have been advanced that one might well doubt that serious divergence of opinion would exist concerning any factor of importance bearing on cesarean section. This happy state can hardly be considered to have arrived, however, if one but scans the more recent publications.

Our clinic is somewhat unusual in the interrelations of its three services. Each admits patients for a twenty-four-hour period in rotation, and the conduct of complicated labor is the responsibility of the chief of service. This arrangement has encouraged lively dispute and discussion through the years, unrestrained yet honest, open and constructive. As a result of constant reappraisal of results in open meetings shared by the three services, settled opinions have been recorded. Thus, after fourteen years and over 30,000 deliveries, we find ourselves largely in agreement on the indications for cesarean section, as well as on the technics to be followed.

We recognize that not all would agree with our attitude toward these problems. It is the purpose of this paper to discuss the most frequently disputed indications and to state the position currently arrived at with respect to them and to the operations preferred.

INDICATIONS

The first problem is that of elective cesarean section for primiparas. One might immediately ask who elects and on what foundation. With cases of obvious fetopelvic disproportion there is no dispute. These, however, form a distinct minor group. The vast majority of cases constitute the so-called "borderline pelvis" group, in which the estimation of the fetopelvic relation establishes a challenge to the most honest and capable attendant in his effort to determine the proper solution. We frankly admit

our inability in many such cases to decide in advance of an adequate test of labor the ability of the patient to deliver herself or to be safely delivered by vagina. We marvel at the judgment and experience of the omniscient, which permit *in advance of labor* appreciation of the size, shape and moldability of the fetal head, the extent of the physiologic relaxation of the pelvic joints, the thickness and tension of the nonosseous pelvic structures, the character and effectiveness of the uterine contractions, the time factor in even partial dilatation and effacement of the cervix, the exact expectation date and the favorable parturitional effect that the unknown, possibly endocrine instigator of labor may exert. Certainly mechanical and x-ray pelvimetry, no matter how accurate, tell none of these things.

With due regard for these factors, we allow sufficient labor in borderline pelvic cases to permit the primiparous patient to demonstrate her capability for vaginal delivery. In patients with premature rupture of the membranes who go into labor late or are seen after what we consider a safe period for a clean operation, with a proper operational armamentarium there is surely no urgency until labor advances. The majority may be expected to progress as if such membrane rupture had not occurred, and the problematical status of the minority puts them in a group for special management in any case. Not many of us now accept premature rupture of the membranes per se as an indication for cesarean section, even when the exact fetopelvic estimation is not clear. We regard x-ray pelvimetry with esteem but without abject deference and place it well below the clinical examination and estimation of the patient's labor prospects. These opinions direct a policy of allowing all primiparas adequate labor except in the presence of obvious disproportion when labor begins.

The role of cesarean section in cardiac patients was formerly highly debatable. We no longer perform it in these cases unless there is an obstetric indication for the operation. Nor do we permit its use solely for the purpose of sterilization, when there are other methods that are so much easier. Between

MARCH. Goddard Hospital. Brockton.

APRIL. State Farm. Bridgewater.

MAY. Lakeville Sanatorium. Lakeville.

It was believed that a hysterectomy would be fatal, for the contraction of the uterus permitted further blood loss and the reappearance of shock. A procedure that I have found life-saving in similar cases was therefore performed. The loose peritoneum at the lateral edges of the incision was dissected to expose the uterine arteries, and these were ligated—but not cut—with ties of No. 2 chromic catgut. Within a few minutes the flabby noncontracting uterus exhibited fibrillary contractions and assumed the crinkled or crepe-paper appearance that indicates response to the induced anoxia.

The intravenous administration of blood, maintenance of the Trendelenburg position, the application of heat and so forth were continued. Four hours postoperatively the pulse was 90 and of good quality and the blood pressure was 124/90. The patient had almost complete anuria for 3 days but thereafter made an uneventful convalescence. There were some residual signs indicating damage to the cerebral nerve tissue from shock-anoxia, but these have since cleared up.

In view of the existing lesions, this patient would probably have succumbed if temporizing measures had been employed.

Our attitude toward pre-eclampsia and eclampsia is definitely conservative. We do not perform cesarean section on patients with eclampsia unless antitoxic measures have checked the eclampsia and made the patient operable. Patients with pre-eclampsia are treated medically unless the toxemia is progressive or recurrent. Termination of the pregnancy is then proceeded with, for we have found that the old practice of carrying the patient along has produced poor results in morbidity and mortality for mother and baby alike. Chesley's² follow-up of our patients shows the earlier the onset of toxemia and the longer it obtains before delivery, the poorer the prognosis for the baby and the worse the end result for the mother. Babies delivered early in a severely toxemic pregnancy have a better chance than those carried to or near term, and permanent damage to maternal structures parallels the duration of the toxemia. The method of terminating the pregnancy is dependent on the severity of the toxemia and associated factors, such as abruption.

Data on 879 cases of mild pre-eclampsia have been recorded. There were no maternal deaths. These cover a five-year period ending in 1940. Cesarean section was performed in 61 cases (6.9 per cent), an incidence approximately twice the clinic incidence. Approximately two thirds of the operations were performed because of fetopelvic disproportion. There were 16 cases of abruption, and in 5 of these cesarean section was performed, with 4 stillbirths.

In 117 cases of severe pre-eclampsia seen during the same period, section was done in 26 (22 per cent). Eleven patients had abruption of the placenta, 4 had cephalopelvic disproportion and 11 had other complications as coexisting indications. The need for cesarean section in severe pre-eclampsia is thus seen to be three times as great as it is in the mild group. The operative mortality was 8 per cent, 2 deaths ensuing when abruption of the placenta complicated the severe toxemia. There were 5 deaths in all,—a mortality of 4 per cent,—4 of them in patients with abruption of the placenta. Since 78 per cent of those with severe pre-eclampsia were delivered vaginally, it is evident that our policy is

to treat all such cases energetically and anticipate vaginal delivery but to resort to cesarean section when progressive or recurrent toxemia is present and in some cases with placental abruption. Section was performed in 11 of 17 patients with abruption occurring with severe toxemia, with 2 deaths. In 6 cases in which the patients were allowed to deliver vaginally, there were 2 deaths. In all 17 cases the infants were stillborn.

From 1931 until November, 1945, we treated 236 cases of eclampsia. Nineteen patients died, a mortality of 8 per cent, and 10 were undelivered. Cesarean section was performed in 20 cases (8 per cent), in 4 of them for severe abruption. In 5 cases section was done on patients with severe toxemia who developed eclampsia post partum, in 15 cases it was done on eclamptic patients. Two patients were operated on while uncontrolled, in opposition to the practice in our clinic. Section was performed in 10 cases one to nine days after the initial convulsion, and in 3 on the day of the first convulsion because of severe placental abruption. There were no maternal deaths following any of the cesarean sections. With elimination of the 5 cases in which eclampsia developed postoperatively, the patients having been progressively pre-eclamptic when operated on, and the 3 cases in which operation was performed for abruption complicating eclampsia, the corrected incidence of cesarean section in eclampsia is seen to be 12, or 5 instead of 8 per cent. This figure clearly indicates our present attitude toward cesarean section in eclampsia. The operation is not employed if we know or believe that the patient is about to have convulsions. It is occasionally done when the convulsive phase has been completely overcome. It is sometimes necessary when abruption of the placenta occurs. But eclampsia should be one of the rarest indications. If it is employed in the convulsive stage, a high mortality, such as that reported by De Normandie³ in his last five-year study—21 per cent of 53 cases—may be anticipated.

From October, 1931, through 1944, we observed 215 known hypertensive patients who went through two hundred and seventy pregnancies. There were 6 maternal deaths, a mortality of 2 per cent. In two hundred and thirteen pregnancies carried past twenty-eight weeks, cesarean section was performed in 28 cases and hysterotomy in 3 of these, with 1 maternal death—a mortality of 4 per cent—and 7 fetal deaths—a mortality of 25 per cent. In one hundred and eighty-five vaginal deliveries, the corresponding mortality rates were 1 and 24 per cent. Two patients died undelivered, and 1 after an abortion at twenty-three weeks. There were 15 cases of abruption, with a total loss of 80 per cent. Eleven patients were delivered vaginally, with no deaths, and on 4 cesarean section was performed, with 1 death due to peritonitis.

January, 1933, and August, 1942, in a series of 578 cases of cardiac disease complicating pregnancy 39 (6.7 per cent) were subjected to cesarean section. The operative incidence, however, dropped from 8 per cent in the first 345 cases to 4.4 per cent in the last 223 cases, with a clinic incidence of 1.3 per cent as compared with one of 15 per cent among 53 private patients.¹

We employ a system of absolute bed rest for patients who have had or are threatened with decompensation, and constant cardiologic supervision for all the seemingly less severe cardiac cases. In this group, the incidence of decompensation has been reduced from 22.3 to 2.5 per cent and the mortality from 3.5 to 0.6 per cent, largely through competent medical care and the elimination of operative interference except for strictly coincidental obstetric indications. Such appraisal of experiences supports our proscription of cesarean section on purely cardiac indications, for private and clinic patients alike. The management and conduct of the cardiac patient in labor is determined by the cardiac consultant and the chief of service.

There are few conditions that have aroused more debate on management than has abruption of the placenta or premature separation of the placenta after the twenty-eighth week of pregnancy. We all recognize the occurrence of slight or partial separations that present no clinical problem. We admit the value of early diagnosis of mild cases, especially

cesarean section in a multiparous patient with an effaced cervix approaching full dilatation in whom an abruption develops or in any patient with shock or hemorrhage, without first re-establishing

blood volume, overcoming anoxia and combating shock? Who would refuse this operation when a complete abruption occurs with the cervix and birth tract unready for delivery, when means are readily at hand for combating shock and blood loss? Who dares sit by while an initial response to active measures against shock may cloak disruption of the myometrium and progressive hemorrhage into the broad ligaments and peritoneal cavity? The answers fix the policy of the clinic, and the validity of such answers is to be found in the mortality report. Injudicious or poor management means more deaths, and there is no statistical compromise with death. On this basis and on that of the data on our material already published we are willing to be judged.

A brief recital of an extremely severe case, illustrating sequential procedures, follows.

A 40-year-old multigravida was seen on February 21, 1945, about 2 weeks beyond term, in deep shock. The prenatal course had been normal, and there had been no abnormal or toxemic findings 5 and 2 days previously.

The patient fainted in her home and remained unconscious for 8 minutes. There were no other signs or symptoms. A relative, a competent obstetrician, examined her within 15 minutes. At that time she was mentally clear. The blood pressure was 120/60 and the pulse 78, the uterus was relaxed, and the fetal heart beat was present. Since the patient was at or beyond term and had never fainted before, she was sent to the hospital for the purpose of inducing labor.

Half an hour after admission, the patient was in deep shock, with a blood pressure of 64/20 and a pulse of 70, barely palpable, cold wet extremities and poor vascular tone. There was some abdominal tenderness but no pain, and the uterus seemed to have considerably increased in size in 5 days. She became unconscious and almost moribund, no pulse or blood pressure being obtainable. The fetal heart could not be heard.

Intravenous injections of plasma were begun at once and, while bank blood was being cross-matched, glucose solution was concurrently run into the other arm. In 2 hours, forced administration of 750 cc of plasma, 1000 cc of blood and 1000 cc of 10 per cent glucose, together with the administration of oxygen and the usual measures against shock, caused a rise in the blood pressure to 110/70 and a good pulse of 88. The patient regained consciousness, felt well and took an active interest in the proceedings, although she had received 0.03 gm of morphine. There was still no vaginal bleeding. The abdomen was opened and a hugely distended Couvelaire type of uterus was revealed. The lower segment was markedly stretched, and when incised spurted blood to a height of 1 meter. A rapid low transverse cesarean section was done, and the dead fetus, huge clots and the separated placenta were removed. The uterine incision was closed, but the uterus failed to contract under stimulation or the intravenous and intra-uterine injection of oxytocics.

in toxemic and primiparous patients, which may presently progress to the severest form. Most of us are not misled by the amount of external blood loss usually noted in over 80 per cent of mild and severe cases alike. The degree of shock is dependent on myometrial disruption as well as on blood loss, and it is frequently difficult to know which of these is more responsible for associated symptoms. If one admits the existence of the mild, the progressive and finally the complete abruption, with its dramatic picture and disastrous possibilities, one must also agree that each presents its own problem and requires its own solution. Who would perform

It was believed that a hysterectomy would be fatal, for the retraction of the uterus permitted further blood loss and the reappearance of shock. A procedure that I have found effective in similar cases was therefore performed. The loose peritoneum at the lateral edges of the incision was dissected to expose the uterine arteries, and these were ligated — but not cut — with ties of No. 2 chromic catgut. Within a few minutes the flabby noncontracting uterus exhibited fibrillary contractions and assumed the crinkled or crepe-paper appearance that indicates response to the induced anoxia.

The intravenous administration of blood, maintenance of the Trendelenburg position, the application of heat and so forth were continued. Four hours postoperatively the pulse was 90 and of good quality and the blood pressure was 124/90. The patient had almost complete anuria for 3 days but thereafter made an uneventful convalescence. There were some residual signs indicating damage to the cerebral nerve tissue from shock-anoxia, but these have since cleared up.

In view of the existing lesions, this patient would probably have succumbed if temporizing measures had been employed.

Our attitude toward pre-eclampsia and eclampsia is definitely conservative. We do not perform cesarean section on patients with eclampsia unless antitoxic measures have checked the eclampsia and made the patient operable. Patients with pre-eclampsia are treated medically unless the toxemia is progressive or recurrent. Termination of the pregnancy is then proceeded with, for we have found that the old practice of carrying the patient along has produced poor results in morbidity and mortality for mother and baby alike. Chesley's² follow-up of our patients shows the earlier the onset of toxemia and the longer it obtains before delivery, the poorer the prognosis for the baby and the worse the end result for the mother. Babies delivered early in a severely toxemic pregnancy have a better chance than those carried to or near term, and permanent damage to maternal structures parallels the duration of the toxemia. The method of terminating the pregnancy is dependent on the severity of the toxemia and associated factors, such as abruption.

Data on 879 cases of mild pre-eclampsia have been recorded. There were no maternal deaths. These cover a five-year period ending in 1940. Cesarean section was performed in 61 cases (6.9 per cent), an incidence approximately twice the clinic incidence. Approximately two thirds of the operations were performed because of fetopelvic disproportion. There were 16 cases of abruption, and in 5 of these cesarean section was performed, with 4 stillbirths.

In 117 cases of severe pre-eclampsia seen during the same period, section was done in 26 (22 per cent). Eleven patients had abruption of the placenta, 4 had cephalopelvic disproportion and 11 had other complications as coexisting indications. The need for cesarean section in severe pre-eclampsia is thus seen to be three times as great as it is in the mild group. The operative mortality was 8 per cent, 2 deaths ensuing when abruption of the placenta complicated the severe toxemia. There were 5 deaths in all, — a mortality of 4 per cent, — 4 of them in patients with abruption of the placenta. Since 78 per cent of those with severe pre-eclampsia were delivered vaginally, it is evident that our policy is

to treat all such cases energetically and anticipate vaginal delivery but to resort to cesarean section when progressive or recurrent toxemia is present and in some cases with placental abruption. Section was performed in 11 of 17 patients with abruption occurring with severe toxemia, with 2 deaths. In 6 cases in which the patients were allowed to deliver vaginally, there were 2 deaths. In all 17 cases the infants were stillborn.

From 1931 until November, 1945, we treated 236 cases of eclampsia. Nineteen patients died, a mortality of 8 per cent, and 10 were undelivered. Cesarean section was performed in 20 cases (8 per cent), in 4 of them for severe abruption. In 5 cases section was done on patients with severe toxemia who developed eclampsia post partum, in 15 cases it was done on eclamptic patients. Two patients were operated on while uncontrolled, in opposition to the practice in our clinic. Section was performed in 10 cases one to nine days after the initial convulsion, and in 3 on the day of the first convulsion because of severe placental abruption. There were no maternal deaths following any of the cesarean sections. With elimination of the 5 cases in which eclampsia developed postoperatively, the patients having been progressively pre-eclamptic when operated on, and the 3 cases in which operation was performed for abruption complicating eclampsia, the corrected incidence of cesarean section in eclampsia is seen to be 12, or 5 instead of 8 per cent. This figure clearly indicates our present attitude toward cesarean section in eclampsia. The operation is not employed if we know or believe that the patient is about to have convulsions. It is occasionally done when the convulsive phase has been completely overcome. It is sometimes necessary when abruption of the placenta occurs. But eclampsia should be one of the rarest indications. If it is employed in the convulsive stage, a high mortality, such as that reported by De Normandie³ in his last five-year study — 21 per cent of 53 cases — may be anticipated.

From October, 1931, through 1944, we observed 215 known hypertensive patients who went through two hundred and seventy pregnancies. There were 6 maternal deaths, a mortality of 2 per cent. In two hundred and thirteen pregnancies carried past twenty-eight weeks, cesarean section was performed in 28 cases and hysterotomy in 3 of these, with 1 maternal death — a mortality of 4 per cent — and 7 fetal deaths — a mortality of 25 per cent. In one hundred and eighty-five vaginal deliveries, the corresponding mortality rates were 1 and 24 per cent. Two patients died undelivered, and 1 after an abortion at twenty-three weeks. There were 15 cases of abruption, with a total loss of 80 per cent. Eleven patients were delivered vaginally, with no deaths, and on 4 cesarean section was performed, with 1 death due to peritonitis.

January, 1933, and August, 1942, in a series of 578 cases of cardiac disease complicating pregnancy 39 (6.7 per cent) were subjected to cesarean section. The operative incidence, however, dropped from 8 per cent in the first 345 cases to 4.4 per cent in the last 223 cases, with a clinic incidence of 1.3 per cent as compared with one of 15 per cent among 53 private patients.¹

We employ a system of absolute bed rest for patients who have had or are threatened with decompensation, and constant cardiologic supervision for all the seemingly less severe cardiac cases. In this group, the incidence of decompensation has been reduced from 22.3 to 2.5 per cent and the mortality from 3.5 to 0.6 per cent, largely through competent medical care and the elimination of operative interference except for strictly coincidental obstetric indications. If one admits the existence of the mild, the progressive and finally the complete abruption, with its dramatic picture and disastrous possibilities, one must also agree that each presents its own problem and requires its own solution. Who would perform

were so. The uterus at term is an organ well protected by nature to withstand infection, else most women would die. Its excellent blood supply, the diminished lymphatic and venous drainage with post-parturient contraction, the return to pelvic location early in involution, late cervical contraction with adequate external drainage and the increase at term of the natural resistance to bacterial invasion all indicate control of uterine infection if no peritonitis has been induced. Patients with foul intrauterine infections do not die either after extraperitoneal cesarean section or after eventual delivery by vagina. But if they have had a classic or low-segment cesarean section they often do, and peritonitis kills most of those dying after Porro operations. The surgeon who performs a Porro operation always assumes that without it the patient would have died, but with an extraperitoneal operation the patient would have recovered in any case. The figures from appreciable groups of cases could be allowed to speak for themselves, without "correcting" for certain deaths. We no longer believe that patients die from myometritis, parametritis or pelvic cellulitis provided that the infected areas are drained, but they still die from peritonitis. In

all septic parturient patients, the peritoneal cavity should not be opened. How better can one obey than with an extraperitoneal cesarean section? And except for vaginal delivery, there is no other way.

The operation in itself is an anatomical one of moderate difficulty but certainly presents no challenge to the obstetrician of surgical competence. The second-time hernia operation by the anatomy-wise and adept intern is generally a creditable one. The same can be said for the extraperitoneal operation. Either the paravesical (Latzko) or the supra-vesical (Waters) approach is good, with definite advantages favoring the latter. The majority of operations in our clinic are now performed with this technique.

THE TREATMENT OF BACTERIAL ARTHRITIS WITH PENICILLIN*

HAROLD L. HIRSH, M.D.,† HENRY L. FEFFER, M.D.,‡ AND HARRY F. DOWLING, M.D.§

WASHINGTON, D. C.

UNTIL the discovery of penicillin, the methods of treating the infectious arthritides were not entirely satisfactory. Although the sulfonamides were often valuable, the results obtained with them left much to be desired. The superior antibacterial action of penicillin in vitro justified a trial of this agent in certain bacterial infections of the joints. The present report is an account of our experience with penicillin in the treatment of 26 patients with bacterial arthritis.

GONOCOCCAL ARTHRITIS

Seventeen patients with gonococcal arthritis were treated with penicillin (Table 1). The diagnosis was made in 9 cases by culturing gonococci from the joint fluid and in 8 cases by finding gram-negative diplococci in a smear of the joint fluid. Thirteen of the patients also exhibited a local genital or urinary infection from which gonococci were cultured or which showed gram-negative diplococci on smear. There were 9 men and 8 women. In 15 cases the

arthritis was acute, having been present for less than a month in each. In the remaining 2 patients the disease had been present for three and six months, respectively.

The patients with acute gonococcal arthritis may be divided into two groups according to the kind of treatment received. The 7 patients in Group A were given penicillin intramuscularly for short periods, ranging from eight to thirty hours. One patient (Case 3) was given a second and a third course of intramuscular penicillin of seventy-two and one hundred hours' duration, respectively. Another patient (Case 6) received an injection of 50,000 units of penicillin intra-articularly, in addition to 80,000 units intramuscularly. A third patient (Case 7) was given 100,000 units of penicillin orally every two hours for forty-eight hours, followed by intermittent intramuscular injections to a total of 550,000 units. There was no improvement of the arthritis in any case, although local genitourinary infections, whenever present, cleared up completely. With the exception of 1 patient who left the hospital against advice, all these patients finally recovered on symptomatic measures, sulfonamides or fever therapy.

Because of the complete failure of these short courses of penicillin, it was decided to treat for at

*From the George Washington Medical Division and the Orthopedic Service, Gallinger Municipal Hospital and the Department of Medicine, George Washington University.

Another indication for cesarean section is placenta previa. Of 341 cases observed from January 1, 1932, through 1941, cesarean section was performed in 104, with no deaths. Among the 237 patients delivered vaginally there were 2 deaths.

TECHNICS

In general, any type of cesarean section is relatively easy to perform. Previously it was largely in the hands of general surgeons, because most of those who delivered babies knew nothing about surgery. Although more adequate training in surgery and the application of surgical principles and technics have accelerated the surgical advance of obstetrics, too often there are adherence to old and outmoded procedures and hesitancy to utilize newer operations of proved worth. The surgical inferiority complex ill mantles the modern obstetrician; he must forget his midwife ancestry. He must be capable of successfully dealing with the technics and complications not only of any type of vaginal delivery but also of any type of abdominal delivery.

There are three major abdominal operations in obstetrics—transperitoneal section, extraperitoneal section and cesarean hysterectomy. The classic

Although the mortality figures for classic section and for the low-segment operation do not materially differ when done electively in good-risk patients not in labor and with intact membranes, the low-segment operation must be chosen for its lower morbidity, smoother convalescence and lessened incidence of subsequent rupture of the uterine scar. When the membranes have been ruptured or the patient has been long in labor or has been subjected to repeated examination, it is far superior. It is time for all obstetricians to learn and use an acceptable form of low-segment operation, and to cease justifying continued use of the antiquated classic section. Our own preference is for the low-segment operation with transverse cervical or isthmal incision. This means combining the old Kehrer technic with the Munro-Kerr incision placed low on the isthmal segment, as advocated and popularized by Phaneuf. In more than 2000 cesarean sections performed in this clinic during the last fourteen years, low-segment operations have been chosen in 69 per cent of cases (Table 3).

We believe that the Porro operation as employed in septic cases is an antiquated operation headed for the limbo of ancient and unused technics. Our

TABLE 3 Cesarean-Section Data (October 1, 1931, to January 1, 1945)

TYPE OF DELIVERY	NO OF DELIVERIES	NO OF DEATHS	MORTALITY	
			%

Vaginal	1	0		

operation is reserved for the last, when it precedes removal of the uterus. This applies to degenerating fibroids and those obstructing the birth canal, and uterine rupture. Using the classic operation rather than the low-segment operation in cases of placenta previa represents a poor conception of the anatomic relations of the placenta, uterus and blood supply. The major portion of a placenta previa is not located in the lower segment, and with transverse incision a lesser amount is incised. More positive suture control of the placental site is possible along the line of incision, and the thinner segment carries far fewer vessels. The uterine content and blood spill are kept out of the abdominal cavity, and more accurate estimation of blood loss is possible. The thin uterine wall is grasped with T clamps, and hemostasis is easily obtained while suturing proceeds. There is no valid reason for electing the classic operation in placenta previa, and in my opinion the low-segment operation is always better and safer.

experience with extraperitoneal operations during the last fourteen years shows a mortality rate far lower than that of comparable groups of Porro operations. It also indicates the needless sacrifice of uteri in Porro operations, and has caused us to reconsider our ideas on the manner of death in post-partum cesarean sepsis. The data from our clinic regarding extraperitoneal sections have recently been published⁴ and will not be reviewed in detail. Septic deaths after section are usually due to peritonitis. In De Normandie's³ last five-year report from Massachusetts, 39 per cent of the 273 deaths following cesarean section were from sepsis and another 10 per cent from embolus. There was a 4 per cent loss after extraperitoneal section. The hackneyed chant from the Porroites continually threatens us with the dire happenings that will follow retention of an infected uterus in the abdomen. This is voluble nonsense unsupported by facts. We could not possibly show a mortality of 1 per cent in over 500 cases of extraperitoneal section if this

were so. The uterus at term is an organ well protected by nature to withstand infection, else most women would die. Its excellent blood supply, the diminished lymphatic and venous drainage with post-parturitional contraction, the return to pelvic location early in involution, late cervical contraction with adequate external drainage and the increase at term of the natural resistance to bacterial invasion all indicate control of uterine infection if *no peritonitis has been induced*. Patients with foul intrauterine infections do not die either after extraperitoneal cesarean section or after eventual delivery by vagina. But if they have had a classic or low-segment cesarean section they often do, and peritonitis kills most of those dying after Porro operations. The surgeon who performs a Porro operation always assumes that without it the patient would have died, but with an extraperitoneal operation the patient would have recovered in any case. The figures from appreciable groups of cases should be allowed to speak for themselves, without "correcting" for certain deaths. We no longer believe that patients die from myometritis, parametritis or pelvic cellulitis provided that the infected areas are drained, but they still die from peritonitis. In

all septic parturient patients, the peritoneal cavity should not be opened. How better can one obey than with an extraperitoneal cesarean section? And except for vaginal delivery, there is no other way.

The operation in itself is an anatomical one of moderate difficulty but certainly presents no challenge to the obstetrician of surgical competence. The second-time hernia operation by the anatomy-wise and adept intern is generally a creditable one. The same can be said for the extraperitoneal operation. Either the paravesical (Latzko) or the supravescical (Waters) approach is good, with definite advantages favoring the latter. The majority of operations in our clinic are now performed with this technic.

THE TREATMENT OF BACTERIAL ARTHRITIS WITH PENICILLIN*

HAROLD L. HIRSH, M.D.,† HENRY L. FEFFER, M.D.,‡ AND HARRY F. DOWLING, M.D.§

WASHINGTON, D. C.

UNTIL the discovery of penicillin, the methods of treating the infectious arthritides were not entirely satisfactory. Although the sulfonamides were often valuable, the results obtained with them left much to be desired. The superior antibacterial action of penicillin in vitro justified a trial of this agent in certain bacterial infections of the joints. The present report is an account of our experience with penicillin in the treatment of 26 patients with bacterial arthritis.

GONOCOCCAL ARTHRITIS

Seventeen patients with gonococcal arthritis were treated with penicillin (Table I). The diagnosis was made in 9 cases by culturing gonococci from the joint fluid and in 8 cases by finding gram-negative diplococci in a smear of the joint fluid. Thirteen of the patients also exhibited a local genital or urinary infection from which gonococci were cultured or which showed gram-negative diplococci on smear. There were 9 men and 8 women. In 15 cases the

arthritis was acute, having been present for less than a month in each. In the remaining 2 patients the disease had been present for three and six months, respectively.

The patients with acute gonococcal arthritis may be divided into two groups according to the kind of treatment received. The 7 patients in Group A were given penicillin intramuscularly for short periods, ranging from eight to thirty hours. One patient (Case 3) was given a second and a third course of intramuscular penicillin of seventy-two and one hundred hours' duration, respectively. Another patient (Case 6) received an injection of 50,000 units of penicillin intra-articularly, in addition to 80,000 units intramuscularly. A third patient (Case 7) was given 100,000 units of penicillin orally every two hours for forty-eight hours, followed by intermittent intramuscular injections to a total of 550,000 units. There was no improvement of the arthritis in any case, although local genitourinary infections, whenever present, cleared up completely. With the exception of 1 patient who left the hospital against advice, all these patients finally recovered on symptomatic measures, sulfonamides or fever therapy.

Because of the complete failure of these short courses of penicillin, it was decided to treat for at

least five days all patients subsequently admitted. The 8 patients treated in this manner are listed in Group B. They were given amounts of penicillin totaling 925,000 to 2,000,000 units. In every case the symptoms and signs of joint disease completely subsided during the course of treatment and did not return. These patients have been kept under observation for periods varying from one to five months without any recurrence of their arthritis.

The 2 patients with chronic arthritis caused by the gonococcus were each given several short courses of penicillin. In addition, 1 was given three intra-

pneumococcus in 1 case each. Five of the 7 patients with staphylococcal arthritis recovered. Three of these were treated with intra-articular penicillin. The fourth (Case 21) received the drug by continuous intravenous administration. The fifth patient (Case 22) was given penicillin intramuscularly and when he failed to improve on this regime, supplemental intra-articular injections were employed. In Case 20, the joint healed following three injections of penicillin into the joint cavity, but the swelling and tenderness in the periarticular tissues improved more slowly and some induration and thick-

articular injections in amounts varying from 50,000 to 200,000 units. Although the urethritis that was present in 1 case subsided completely, the administration of penicillin had no effect on the condition of the joints in either patient. Both patients later received fever therapy in a hypertherm cabinet, with complete resolution of the arthritis.

STAPHYLOCOCCAL, STREPTOCOCCAL AND PNEUMOCOCCAL ARTHRITIS

Nine patients with other types of bacterial arthritis were treated with penicillin (Table 2). Staphylococci were isolated from the joint fluids in 7 cases and a hemolytic streptococcus and a Type 12

ening of these tissues remained. Two months later the swelling of these tissues increased, redness and heat reappeared, and a low-grade fever supervened. Penicillin administered intramuscularly resulted in a complete recovery within two weeks.

Both the patients with staphylococcal arthritis in whom penicillin therapy failed were treated at a time when the drug was scarce. Both had bacteremia as well as inflammation of a knee joint. One patient (Case 23) was given sulfamerazine by mouth and penicillin intra-articularly in daily injections of 50,000 units. Although penicillin concentrations of 0.156 to 0.625 units per cubic centimeter were maintained in the joint fluid—levels that were

found to be bactericidal for the patient's organism — staphylococci continued to be obtained on culture. The patient finally died of staphylococcal bacteremia

The other patient in whom treatment failed (Case 24) was given penicillin intramuscularly in doses of 20,000 units every four hours and in the knee joint in amounts of 10,000 units each day. Under this regime, the local bacteremia remained uncontrolled and the infection extended into the lower end of the femur, resulting in an osteomyelitis and periostitis. An arthrotomy was performed so that penicillin could be instilled into the joint through a catheter. When there was no improvement after this regime had been followed for three weeks, penicillin was

DISCUSSION

In view of the startling success of penicillin therapy in gonorrhea, one might expect similarly excellent results in acute arthritis caused by the gonococcus. Actually, the value of penicillin in the latter condition is an unsettled question at the present time. Thompson,¹ Bloomfield et al.² and Josey and Kirshman³ obtained no benefit from the use of penicillin in their patients with gonococcal arthritis. On the other hand, some investigators⁴⁻¹¹ report excellent results in small series of patients. In some cases, the arthritis responded to a short course of penicillin administered for the primary genitourinary infection, whereas others required a longer course

*Two months later intramuscular penicillin was given for residual periarticular inflammation

†Still receiving penicillin intramuscularly for possible acute tricuspid endocarditis.

discontinued. The joint was then placed in a cast, and the patient made a gradual but complete recovery.

One patient with arthritis of the left knee, caused by a beta-hemolytic streptococcus (Case 25) was given doses of penicillin varying from 50,000 to 200,000 units directly into the joint every second or third day over a period of eight days. Although the arthritis improved rapidly, swelling and tenderness of the periarticular tissues remained until penicillin was also administered intramuscularly, whereupon the entire infection healed completely.

A pneumococcal arthritis of the knee joint without any evidence of infection elsewhere was present in Case 26. At first, daily intra-articular injections of 15,000 units were administered. When improvement on this regime was incomplete, the dose was changed to 12,500 units twice per day. This was continued for fifteen days, by which time the patient had completely recovered.

or several courses. Most of these authors do not state whether there was swelling of the joints or other local signs of inflammation or whether the joint fluid contained leukocytes or bacteria.

The present study was confined to patients with an increased amount of fluid in one or more joints, which either yielded gonococci on culture or showed them on smear. The first 7 patients were given penicillin intramuscularly for periods of eight to thirty hours or, as in 1 case, orally for forty-eight hours. These regimes were uniformly unsuccessful, even though additional short courses of intramuscular penicillin were given to 2 patients and penicillin was injected into the knee joint of another. Since it was concluded that more prolonged treatment was necessary, each patient was given intramuscular injections approximating 10,000 units an hour for a period of at least five days. Of 8 patients so treated, improvement was not apparent for at least three days in 5 and not for five to eight days in 3. All

8 of the patients with acute arthritis treated by this method recovered completely

Our experience with chronic gonococcal arthritis has been limited. The 2 patients treated did not improve when given intramuscular penicillin, supplemented in 1 case by three intra-articular injections. In view of the results in patients with the acute form of the disease, better results might have been obtained in chronic arthritis if treatment had been extended over a longer period.

When one turns to the treatment of arthritis caused by the staphylococcus, streptococcus hemolyticus and pneumococcus, two principles are evident. First, penicillin should be injected into the joint in amounts and at intervals sufficient to provide a continuous bactericidal concentration. For the strains encountered we have found that doses of 50,000 units every second day or 100,000 units every third day are sufficient for this purpose. The second principle of treatment is that penicillin should be given systemically in adequate amounts and for long enough periods to combat extra-articular infection. It is probably best to administer it systemically to all patients for the first few days. In patients with bacteremia, inflammation of periarticular tissues or infections elsewhere in the body and in those who may be suspected of developing an osteomyelitis, systemic penicillin therapy should be continued until all evidences of infection have disappeared.

SUMMARY AND CONCLUSIONS

Twenty-six patients with bacterial arthritis were treated with penicillin. Seventeen of them had gonococcal arthritis, 7 had staphylococcal arthritis, and 1 each had arthritis caused by the hemolytic streptococcus and the pneumococcus.

Successful results were obtained in acute gonococcal arthritis when penicillin was administered

systemically in adequate doses, and in arthritis caused by the staphylococcus, the hemolytic streptococcus and the pneumococcus when adequate amounts of penicillin were injected into the joint, accompanied by penicillin systemically in patients with extra-articular infection.

The following dosage schedules are recommended. In acute gonococcal arthritis, 25,000 units should be injected intramuscularly every three hours for at least five days, or longer if needed. In arthritis caused by the staphylococcus, the beta-hemolytic streptococcus or the pneumococcus, 30,000 to 50,000 units should be administered intra-articularly on alternate days until local and general signs of inflammation have disappeared. If extra-articular infection is present, penicillin should also be given intramuscularly in amounts of 25,000 units every three hours.

THREE YEARS' EXPERIENCE WITH ELECTRIC CONVULSIVE THERAPY

JACOB NORMAN, M.D.,* AND JOHN T. SHEA, M.D.†

FOXBOROUGH, MASSACHUSETTS

ELECTRIC convulsive therapy has been used for the last three years at the Foxborough State Hospital and has become the chief form of physical therapy in the treatment of psychoses of psychogenic origin and of severe psychoneuroses. During this period 266 patients have been treated, as follows: schizophrenia, 175 cases, manic-depressive psychosis, 51 cases, involutional melancholia, 24 cases, and psychoneurosis, 16 cases. The majority of the schizophrenic patients had been in the hospital for periods ranging from one to thirty years and showed definite deterioration.

In all newly admitted functional cases, an attempt was made to obtain permission for shock therapy, especially in cases in which the patient presented serious difficulties in hospital care, such as combativeness, resistance to feeding, mutism, suicidal and homicidal tendencies and assaultiveness. Permission for treatment was readily obtained in 60 per cent of these cases.

During the first year of use of electric convulsive therapy, we tended to be conservative and in most cases waited two or three months before recommending the treatment. As time went on, experience convinced us that the time element is a great factor in the prognosis of shock therapy for schizophrenia and that the number of remissions proportionately decreases in relation to the length of illness. Of late it has been our policy to recommend this therapy early, and as a rule it is begun within thirty days following admission.

The criteria adopted for the selection of chronic cases for this treatment were rather broad. An attempt was made to obtain permission for treatment in cases that presented a syndrome of depression, agitation, guilt feelings and retardation, regardless of the diagnosis made. A large group of cases, most of which were those of chronic dementia praecox, were treated mainly because of requests coming from the patient's family, regardless of the duration of the illness and the type of onset. It is only during the last year that we have been reluctant to treat large numbers of old, deteriorated schizophrenic patients. Another group of chronic cases were selected for treatment because of the difficulties presented in their care, and the object was to modify symptoms to a point at which the patients would make a better hospital adjustment.

We have found that giving treatments three times weekly has met the therapeutic requirements for most patients. The number of treatments given

varied greatly. The acutely ill patients required a smaller number of treatments than did the chronic cases. The manic-depressive depressed and involutional melancholia cases required fewer treatments than did the manic-depressive manic cases. The schizophrenic patients in general required a larger number of treatments. In the treatment of chronic schizophrenic cases, we were governed by the reported experiences of Kalinowsky,¹ giving twenty treatments and, if improvement was evident, another series of ten to fifteen treatments after a rest interval of two or three weeks, even if the patient lost all the improvement gained from the first series. If no improvement was noted after the series of twenty treatments, no further treatment was given except that in 12 cases of chronic schizophrenia fifty treatments were given, regardless of the fact that the patients did not improve after the first twenty. During the course of these fifty treatments, several patients began to show organic psychotic symptoms, such as untidiness, impairment of intellectual functions and marked regression, and therapy was interrupted for several weeks until these symptoms subsided. In all treated cases, whenever marked confusion was evidenced treatment was interrupted until the confusion had disappeared. In the technic of treatment, it was the object always to produce a major convulsion, since it was observed that in some cases a subconvulsive seizure delayed improvement.

In the manic-depressive depressed cases, good results were obtained from an average of eight treatments. The involutional melancholia cases required an average of fifteen treatments. The manic-depressive manic cases required an average of twenty treatments. In the acute schizophrenic group with a sudden onset, ten to twelve convulsions sufficed. The chronic schizophrenic cases with an insidious onset were refractory to any number of treatments. We have no experience in the use of combined electro-shock and insulin therapy in the latter group.

All improved cases received a certain amount of psychotherapy and reorientation during and following treatment. In a small number of cases, an attempt was made during treatment to give more intensive psychotherapy, in the hope that this would decrease the number of shock treatments required and at the same time give the patient a deeper insight into his problems. The results did not indicate that this method was practical. As soon as the patient became accessible to psychotherapy he invariably occupied his interview with statements to the effect that he had been sick but

*Senior physician Foxborough State Hospital

†Assistant superintendent Foxborough State Hospital

was now well, ready to go home and not interested in discussing his problems. In addition, the patient's relatives, as soon as they observed improvement, began to press for early home visits, which interrupted attempts at intensive psychotherapy.

In the majority of improved treated cases, the patient soon began to object to further treatment and had a tendency to cover up his remaining symptoms in an effort to convince the physician that treatment should be discontinued. This attitude is not conducive to a frank and open discussion of existing psychogenic problems and conflicts. In view of this, it seems that intensive psychotherapy must of necessity be carried on after the patient's release from the hospital. Although these patients are required to report at the hospital at regular intervals, — approximately once a month for one year, — this is not sufficient for intensive psychotherapy. An exception to this conclusion was encountered in the psychoneurotic group, in which a few electric-shock treatments greatly facilitated psychotherapy.

Although the maximum number of shock treatments has not been definitely established and some clinicians advocate the administration of three or four series of twenty treatments each, one often doubts that this is a sound therapeutic procedure, especially in view of the much more favorable results reported in chronic schizophrenia with insulin-shock therapy.

During the three years in which we have employed electric-shock therapy, approximately 4000 treatments have been administered and complications have been negligible. There have been no fatalities and no fractures of the spine or other bones. Temporary confusion and more prolonged impairment of memory were the most frequently encountered complications. In some cases impairment of memory lasted for three months after cessation of therapy. In the cases that received fifty treatments, some patients showed symptoms pointing to the possibility of organic brain damage.

One patient developed signs of active pulmonary tuberculosis after receiving his fifteenth convulsive shock. Another developed pulmonary tuberculosis three months after receiving fifty treatments. A young, robust male patient developed pleural effusion with high fever during the course of convulsive therapy.

Four patients with the diagnosis of dementia praecox, paranoid type, developed definite assaultive tendencies during the treatment, and 2 of these threatened suicide and made suicidal gestures. Two patients developed grand-mal seizures within two months of cessation of treatment.

CLINICAL RESULTS AND DISCUSSION

The difficulties encountered in evaluating the clinical response to this type of therapy are many

and are no doubt the cause of the great discrepancies noted in the results obtained in reports from different hospitals. The greatest disagreements noted are in the reported results in schizophrenia. The cases included under this heading represent a heterogeneous group with a great variation in etiology and prognosis. The results obtained from electro-shock therapy therefore depend greatly on the type of cases selected for treatment.

To evaluate this empirical therapeutic agent, our results must be compared with those obtained in the same hospital before institution of this therapy, and also with those obtained in other hospitals with electroconvulsive treatment.

Kalinowsky¹ and Lowinger and Huddleson² have emphasized that the efficacy of electric-shock therapy in schizophrenia depends on the length of illness before treatment is instituted and the intensity with which treatment is given. In acute schizophrenic cases Kalinowsky reported 68 per cent remissions, whereas in chronic cases he reported only 9 per cent. Many clinicians obtained no remissions in cases with a duration of two years or more.

We too have learned that the time element is of great importance in the prognosis to be expected from shock therapy, but we believe that the mode of onset, the age of the patient at onset, the severity of symptoms and evidence of marked maladjustment beginning in adolescence are the best criteria for prognosis. We have failed to obtain remissions in several acute cases of schizophrenia regardless of the number of treatments prescribed. In these cases the failure could not be ascribed to the length of illness or the lack of intensive treatment. In certain cases, in spite of repeated courses of this therapy we witnessed the return of a foggy, dreamy, confused state after only a few lucid days.

There are also technical difficulties encountered in reporting statistical results of electric-shock treatment. Acute schizophrenia gave a high percentage of remissions, ranging from 60 to 75 per cent, whereas in patients who had been ill for a year or more before treatment was begun the remissions ranged from 2 to 9 per cent. Any report of results that lumps together these two groups is extremely misleading.

There were also certain patients who after treatment had a full remission that lasted sufficiently long to accomplish their discharge from the hospital but promptly developed another episode, were readmitted as new cases, were treated again and were once more released. Others were subsequently admitted to other hospitals for treatment. In some reports these cases appear several times as recovered cases.

In certain reports it is noted that patients improved but required weekly treatments outside the hospital to maintain this improvement. We have such cases, but it is our opinion that they cannot

be considered as improved and are not properly classified as such

In addition, there is always a group of schizophrenic patients who present many symptoms of an affective psychosis and are often described as having schizo-affective disorders. Most of these cases have a good prognosis with any form of treatment and do not necessarily prove the effectiveness of electro-shock therapy in schizophrenia. One is often tempted to revise this diagnosis in reviewing these cases.

For purposes of simplification, our results are recorded in two groups — that of patients who recovered or were much improved and are living outside the hospital, and that of patients not well enough to leave the hospital (Table 1).

Of the 175 schizophrenic patients treated, 120 had been ill for one year or more and 55 had been ill for less than one year. With the latter the re-

mission rate was 62 per cent, with an average hospitalization period of less than six months, with the former the remission rate was 7 per cent. In patients with manic-depressive psychoses, the remission rate was 70 per cent, with the average hospitalization period seven months. In involutional melancholia, the remission rate was 48 per cent, and in psychoneurosis, 80 per cent. Our results on the whole do not differ greatly from those obtained by Kalinowsky in his report of 1500 cases. He gives his remission rates as follows: manic-depressive psychosis, 85 per cent, acute schizophrenia, 54 per cent, schizophrenia of two years' or more duration, 9 per cent, involutional melancholia, 85 per cent, and involutional paranoia, 43 per cent.

Our comparatively low figure of 46 per cent of treated patients well enough to live outside the hospital is accounted for by the fact that almost half the 266 patients treated had chronic schizophrenia, and also by the fact that many of the involutional melancholia cases were of the paranoid type. Especially good results were obtained in a group of young women who developed schizophrenic symptoms following delivery, and also in a group in whom fatigue appeared to be a precipitating factor.

In order to compare our results with those obtained in the same hospital prior to the institution of shock therapy, we have reviewed the records of all patients admitted during 1937 and 1938. During this period there were admitted 100 patients diagnosed as having dementia praecox, 60 per cent of these cases were acute. Two years after admission 24 patients had been discharged, 4 had died, and 72 were in the hospital or had been transferred to other hospitals. Of 33 manic-depressive patients, 17 were out of the hospital, and of 17 patients with involutional psychoses, 5 were out of the hospital. The average length of hospital stay for the schizophrenic patients discharged was sixteen months and that for manic-depressive patients was eleven months.

In the second group, — namely, the patients improved but still hospitalized, — the record is as follows. In the whole group of affective disorders treated, all the patients showed slight improvement in behavior and several have been able to go on short visits. The involutional patients who did not improve sufficiently to leave the hospital improved in physical health and are now employed in various hospital departments.

The great majority of the treated patients with chronic schizophrenia gave a history of insidious onset and showed mutism and bizarreness, with flattening of the emotions. They usually showed some improvement after five or six treatments, but as treatment progressed they tended to regress even further than when treatment was instituted. The paranoid schizophrenic patients became more irritable, stubborn, resistive and assaultive, and treatment was discontinued.

A number of patients who presented marked difficulties in management of several years' duration improved with treatment sufficiently to adjust well on the wards with other patients.

CONCLUSIONS

Three years' experience with electric convulsive therapy has convinced us of its efficacy in the treatment of acute psychoses of functional origin. The length of the psychotic episode was definitely shortened, as is indicated in the figures covering patients admitted in 1937 and 1938 who had no shock treatments, the period of hospitalization was less hazardous, and in acute cases the number of remissions was almost doubled.

As regards the efficacy of this form of treatment in schizophrenia, the results are generally good if treatment is instituted early in the disease and if the cases are of sudden onset and do not show early marked regression.

In the treatment of chronic dementia praecox, we are convinced that electric convulsive therapy is not of much value. We do not feel justified in treating 100 patients with the hope of obtaining seven remissions.

TABLE 1 Summary of Clinical Results		
RESULT	NO OF CASES	PERCENTAGE
Recovery or much improvement (outside hospital)		
All patients	123	46
Men	57	52
Women	66	42
Moderate or little improvement (inside hospital)		
All patients	143	54
Men	53	49
Women	90	58

Although we have had no personal experience with insulin-shock therapy or combined electric-shock and insulin-shock therapy, we are impressed by the results reported by other hospitals. It is our hope that as soon as hospital conditions permit we shall be able to treat with insulin a group of cases that proved refractory to electroconvulsive therapy.

Electric-shock therapy is of value as symptomatic treatment in chronic hospital cases presenting marked difficulties in management, provided that

symptoms can be alleviated with a few treatments and that maintenance treatment is not required too frequently.

MEDICAL PROGRESS

GYNECOLOGY CARCINOMA OF THE VULVA

LANGDON PARSONS, M.D.,* AND JOE VINCENT MEIGS, M.D.†

LITTLE progress has been made in the treatment of carcinoma of the vulva during the last five years, except for a more enlightened conception of the natural lymphatic spread of the disease and emphasis on a more radical surgical approach to the deep lymphatic chains.

Among those primarily interested in the disease, the battle for early recognition and preventive treatment has continued. Despite the many articles appearing in the literature, the patient still presents herself to the operating surgeon with a relatively advanced state of malignancy. Through the medium of the radio, which has taken the place of the corner drugstore, home therapy in the form of soothing salves for relief of intolerable itching or pain has often been tried for several months. The medical profession appears to be not entirely blameless, for there are few conditions in the field of malignant disease that are so badly misdiagnosed and maltreated as is carcinoma of the vulva.

The problem therefore revolves around early recognition of the prodromal symptoms on the part of the patient and, similarly, greater alertness on the part of the physician to the early manifestations either of the premalignant state or of the actual presence of the cancerous lesion. The surgeon for his part must adopt a more radical approach to the eradication of the neoplasm, as regards both the initial lesion and its distant spread.

Such a change in attitude on the part of the laity and the medical profession is of the greatest importance, for the disease in its actual course tends

to remain localized for long periods, metastasizing to distant organs slowly, although freely. An attack may therefore be made on the local lesion and the regional lymphatics with a reasonable hope of cure, provided that a radical enough concept is entertained at the time of the initial attack. For the patient to temporize because of a natural reluctance to consult a physician for an itching vulva or for her to prolong self-treatment with ointment, salve or hormones is to underestimate the disease. An inadequate choice of a surgical approach, such as the use of radium or x-ray, partial vulvectomy, hemivulvectomy or complete vulvectomy with a unilateral superficial groin dissection, is to court disaster.

It appears that the dissemination of knowledge regarding the nature of carcinoma of the vulva has been faulty in that neither the public nor the medical profession is aware of the tragic consequences of neglect in a disease that should present one of the highest possibilities of complete cure of any of the cancerous lesions. Undoubtedly this is due in part to the fact that carcinoma of the vulva represents only 4 per cent of the total cases of genital cancer in women. Thus, although any cancer educational program is followed by the appearance in clinics and private offices of many early or suspicious cases of cancer of the cervix or fundus of the uterus, the same cannot be said for cancer of the vulva.

So far as faulty diagnosis on the part of the physician first consulted is concerned, there are several factors at work. One of these is the failure to recognize the true cancerous state, such as the difference between kraurosis and leukoplakia. Likewise, most physicians have been taught that a cancer is, by and large, nontender. For the most part this is true, but the vulva, like the floor of the mouth, is a notable

*Instructor in surgery, Harvard Medical School, visiting surgeon, Massachusetts General Hospital, surgeon, Pondville Hospital, surgeon, Palmer Memorial Hospital.

†Clinical professor of gynecology, Harvard Medical School, chief of the Vincent Memorial Hospital (Gynecological Service), Massachusetts General Hospital, surgeon, Pondville Hospital, gynecologist, Palmer Memorial Hospital.

exception. The tenderness is probably due to superimposed infection, but the fact that the lesion is tender is enough to divert the attention of the physician from entertaining a suspicion of cancer.

The surgeon dealing with carcinoma of the vulva is likely to be confronted with a patient in the older age group, for the mean average age of these patients lies somewhere between fifty-eight and sixty-one years. The lesion may appear to be unilateral, and the nodes in the superficial groin, if considered at all, may be regarded as inconsequential. The surgeon is thus lulled into a sense of security and either attempts a wide local excision or hemivulvectomy or applies radium locally. If he elects to perform a groin dissection, this is usually undertaken at a later date when it is evident that the nodes previously regarded as insignificant represent metastases. If the dissection is done as part of the original operation or as a staged procedure, it is likely to be a superficial removal of the nodes above Poupart's ligament.

In the first place, cancer of the vulva is a disease of the entire vulva, and the surgeon performing a hemivulvectomy or local removal is more often than not confronted with a contralateral neoplasm or a local recurrence. Neoplasms in this area are prone to recur.

As for the lymphatic spread, there is a marked tendency, depending on the location of the initial lesion, both to bilateral invasion of the regional lymphatics in the groin and to invasion of the deep femoral chain located above Poupart's ligament, where the nodes in the obturator area and Cloquet's node along the external iliac vein are frequently involved. None of these areas can be reached by a superficial node dissection in the groin.

It is thus apparent that many surgeons have fallen into the trap of underestimating their opponent while attempting to spare their patients a more formidable surgical experience. If at the end of six months or one year a local recurrence is observed and the nodes of the groin become obviously involved, the patient must then undergo the same degree of surgery when she is one year older and has less chance of a permanent cure.

DIFFERENTIAL DIAGNOSIS

All writers on this subject agree that all tumors of the vulva should be biopsied, whatever the size of the lesion and whatever the age of the patient. Thus, Speisser¹ writes as follows:

A positive diagnosis should never be made solely on the appearance of infected lesions about the external genitals. Grossly similar lesions may result from different etiologic factors or a single agent may produce variable lesions. Since many of the pathognomonic factors may be absent it is well to do routinely a dark-field and serologic examination, smear for Donovan bodies, Ducrey bacillus and fusospirochetes, intradermal test with Ducrey bacillus antigen and the Frei antigen and a microscopic examination after biopsy.

Carcinoma of the vulva is infrequently found in Negroes, but certain writers have found, as Deibert and Greenblatt² have, that genital cancer may be coexistent with, be stimulated by, or form a direct sequel to venereal disease, particularly lymphogranuloma. Eight of the 9 cases of carcinoma of the vulva occurring in the Negroes in Taussig's³ series were preceded by syphilitic or postsyphilitic granulomas.

The reader is referred to the recent excellent articles by Speisser,¹ Taussig³ and Savill⁴ for detailed information on the subject of infectious diseases. Neoplasms in the area of the vulva have been discussed in the recent literature by Norris and Block,⁵ Folsome,⁶ and MacDonald.⁷

PREVENTION

That certain changes in the tissues of the vulva area predispose to malignant transformation is a well known fact. Leukoplakia, for example, is universally regarded as precancerous because of the tendency to epithelial hypertrophy. Thus, Taussig³ found that 71 (45 per cent) of 161 patients with carcinoma of the vulva had a preceding leukoplakia. During the same period he observed twice this number of cases of leukoplakia without carcinoma. In other words, one third proceeded to the development of carcinoma. One would therefore expect prophylactic vulvectomy to produce a cure and reduce the incidence of subsequent cancer. Kraurosis, on the other hand, is an atrophic process developing in elderly women or in castrates and, as Savill⁴ points out, the pre-existing atrophy prevents the development of the hypertrophic state with keratinization seen in leukoplakic vulvitis.

It therefore appears to be a simple process of selection to provide the proper treatment in the prevention of the cancer. Vulvectomy is definitely indicated in leukoplakia, whereas the vulva with kraurosis should readily respond to therapy with estrogens, whether these are applied locally or parenterally, or to vitamin A and dilute hydrochloric acid orally, as suggested by Swift,⁸ who believes that lack of vitamin A with varying degrees of achlorhydria underlies the pathologic state found in kraurosis, leukoplakia and pruritus vulvae.

Unfortunately, despite a voluminous amount of literature, dating back to the Hunterian lectures of Bonney in 1909, regarding the difference between kraurosis and leukoplakia, confusion still exists. It seems that the two conditions may exist simultaneously in the same patient. Graves and Smith¹⁰ and Adair and Davis¹¹ believe that they are one and the same process, whereas Ketron and Ellis¹² think that each may be identified in the early stages, although they may be present together. The problem is thus not quite so simple as it first appears. Excellent descriptive articles bearing on the discussion of the difference between these conditions may be found in the literature. Savill,⁴ Buxton,¹³

Taussig,³ and Norris and Block⁵ have been recent contributors

Perhaps one should adopt the attitude of Norris and Block⁵ toward prophylactic vulvectomy. These authors write

Physiologic atrophy of the vulva predisposed to pathology. The sequence of events would be the development of minute cracks in this early traumatized atrophic area, followed by infection, itching, more trauma through the years, to the final stage of chronic atrophic dermatitis manifest by a smooth, glistening, translucent parchment-like skin in which the pruritus may be intermittent

In this group vulvectomy is advised

Taussig³ found the following possible etiologic factors in the development of carcinoma of the vulva among 155 cases: leukoplakia, 72 cases, syphilis or postsyphilitic vulva, 9, senile warts, 8, Bartholin's abscess, 4, urethral caruncle, 3, trauma, 3, and no lesion, 58. He makes the following recommendations, based on the suggested etiologic factors, concerning prevention of the disease: complete vulvectomy for leukoplakia, with a rigid follow-up, intensive antisyphilitic treatment in tertiary lesions of the vulva, especially in Negroes, removal of warts on the vulva in the postmenopausal age, close observation or excision of enlarged Bartholin's glands after the age of forty, and cautery excision or radium treatment of urethral caruncles.

Estrin Therapy

The use of estrogens, particularly for the pruritus frequently accompanying kraurosis, has become widespread. Taussig³ points out that although estrin therapy may decrease pruritus, a carcinogen may be dangerous on a precancerous leukoplakic base where the underlying pathologic state is one of hypertrophy. It is obvious that in view of the existing confusion on the question whether kraurosis and leukoplakia coexist or are one and the same process, estrin therapy has frequently been used for leukoplakia. Rust,¹⁴ Buxton,¹⁵ Foss,¹⁶ Klasten,¹⁶ and Finkler and Marks¹⁷ report a high percentage of cures, whether the estrogens are applied locally as a salve, rectally in the form of suppositories or parenterally as injections. Savill,⁴ however, believes that most cases are relieved and not cured. The success or failure of the treatment is based on relief obtained from pruritus and burning. Savill thinks that kraurosis of itself has no symptoms and that the pruritus is but a manifestation of infection. Symptoms recur when the infectious foci again become active. Thus, estrin may be said to relieve symptoms, but the improvement is transitory, and moreover its use in leukoplakia vulvitis may be regarded as dangerous.

TREATMENT OTHER THAN RADICAL SURGERY

Radiation

Radiation therapy, either by application or by local infiltration of radium needles or by generalized

x-ray treatment centered over the vulva, has recently been evaluated. The reports are universally discouraging. Healey¹⁸ at the Memorial Hospital in New York City finds that the normal vulva does not tolerate radiation and that prolonged and extensive ulceration results, with slough, causing widespread necrosis of normal tissue, great suffering and actual shortening of life. When attempts were made to treat the local lesion with radium and the groin with x-rays, the local damage was so severe that the latter was either postponed or omitted. Folsome,⁶ who used radiation therapy alone or in combination with surgery in a series of 128 cases, found it to be ineffective. Stoeckel¹⁹ in a compilation of 126 cases found only 12 per cent five-year survivals. Plate²⁰ in England and Graves and Mezer²¹ in this country had no five-year survivors following radiation therapy.

As regards the use of x-ray treatment in distant nodes, Taussig²² states that a metastatic node is more resistant than is the primary lesion. An irradiated node is an uncertain quantity, for, as Stewart and Farrar²³ observe, there are marked differences in radiation response, not only in adjacent nodes but also in different areas in the same node.

The advantage of radiation therapy is that it carries no primary mortality. This is far outbalanced by the complete ineffectiveness of the treatment, not to mention the profound discomfort associated with its use, whether by radium or by x-ray.

RADICAL SURGICAL TREATMENT

Despite the fact that there is a marked tendency for carcinoma of the vulva to metastasize freely, in common with all genital cancer, Taussig²⁴ finds 70 per cent of the cases suitable for the optimum approach to cure—namely, complete vulvectomy with radical bilateral groin dissections. That free metastases do occur is evidenced by the finding of 88 (57 per cent) of 155 cases in Taussig's series and 87 (48 per cent) in the 183 cases of Taylor and Nathanson.²⁵ This is in part due to long delay by the patient in seeking the physician or by the physician in presenting the patient for proper surgery. The delay in Taussig's series of 155 cases was as follows: less than three months, 7 cases; three to six months, 48 cases; seven to twelve months, 24 cases; thirteen to twenty-four months, 34 cases; over two years, 24 cases; and insufficient data, 18 cases. All writers agree that the worst examples of inexcusable delay, mistaken diagnosis and faulty treatment occur in the treatment of carcinoma of the vulva.

Local Lesion

When a diagnosis of malignant tumor of the vulva, at any age, whether or not ulcerated, has once been established by biopsy, a wide vulvectomy, including the perianal skin, should be performed either by

sharp-knife dissection or by diathermy. If the skin cannot be closed, it should be allowed to granulate in. The perineal defect may be closed by a posterior vaginal-wall flap.

Although it is true, as noted by MacDonald,⁷ that low grade basal-cell lesions, so-called "hydradenoma" (sweat-gland carcinoma) and carcinoma in situ (Bowen's disease)^{26, 27} are said to respond to a purely local excision, there appears to be general agreement that there is no place in the treatment of carcinoma of the vulva for a partial vulvectomy or hemivulvectomy. Taylor and Nathanson,²⁵ among others, have pointed out the marked tendency toward the development of double lesions, local recurrence or new lesions in this area. We have had a case in which Bowen's disease recurred after an extensive incision. The treatment of choice for the local lesion in malignant tumors of the vulva is a wide, complete vulvectomy. The treatment is not without its mortality, for Taussig had 4 deaths in patients over seventy-two years of age among 117 cases.

Radical vulvectomy does not always produce a cure. This is certainly due to the relatively advanced state of the disease when first encountered. Taussig²⁴ groups his cases in five stages, as follows: Group 1, patients without palpable metastases, and a tumor 1 to 3 cm in diameter; Group 2, patients without palpable metastases, and a tumor 4 to 7 cm in diameter; Group 3, patients with a tumor over 7 cm in diameter or smaller tumors, with evident but movable metastases; Group 4, patients with extension to the vagina or subpubic space or with large, fixed lymph nodes; and Group 5, far-advanced cases with broken-down lymph nodes and cachexia. The percentage distribution of Taussig's and Folsome's⁶ cases, according to this classification, is given in Table 1. Taussig's figures

of cures is not forthcoming. Taylor and Nathanson advance the most evident reasons. First, there is a high incidence of local recurrence or recurrence of the primary lesion, too many local excisions and hemivulvectomies are done. Second, although 20 per cent of patients have deep-node involvement, groin dissections in the past have been superficial rather than radical. Third, too few bilateral dissections have been done, although a high percentage of patients have bilateral metastases, especially when the midline is encroached on. Fourth, there is reluctance in the older age group to do radical dissections, with a resultant increase in the number of superficial dissections. Lastly, because of the patient's age or the uncertainty of regional node involvement, groin dissection is postponed until too late.

Regional Lymph Nodes

The propensity of the primary lesion, for free metastasis, despite its relatively slow development, has already been commented on. Taylor and Nathanson²⁵ have observed that clinical appraisal is inaccurate in 30 per cent of cases. Thus, only 70 per cent of the nodes regarded as positive are correctly diagnosed. This is largely due to the associated inflammation frequently accompanying lesions of the vulva. The more important observation, however, is that when no nodes are palpable in the groins, radical dissection shows metastatic involvement in 30 per cent. Thus, when in the case of an elderly woman the surgeon pursues a policy of watchful waiting, under the misguided impression that he is following a conservative course of therapy, he is doing so with one strike already called against him, of which he is unaware. No experienced gambler would take this chance. In 55 per cent of cases the nodes are manifest within the first year, whereas in 70 per cent they appear within two years, the average mean time is six months. Twenty-two per cent demonstrate a belated appearance of nodes, but almost invariably this train of events follows a recurrence of the primary lesion. Thus, to postpone groin dissection because of the age of the patient is to increase by one or two years the age at which she must undergo radical surgery and to decrease her chance of cure.

Some indication of the likelihood of cancerous involvement is given by the size of the palpable node in the groin. As previously stated, 30 per cent are positive when no nodes are palpable, and Taussig found that 18 per cent were positive when the nodes were smaller than 1 cm. When the node is greater than 1 cm, 64 per cent are positive.

Likewise, a consideration of the primary lesion may be helpful in determining the likelihood of regional node metastases. In general it may be said that the size of the lesion is the most important single factor. Undoubtedly this bears a relation to the tendency to encroach on the midline, where

TABLE 1 *Classification of Cases of Carcinoma of Vulva*

GROUP	NO OF CASES		PERCENTAGE	
	TAUSSIG	FOLSOME	TAUSSIG	FOLSOME
1	28	10	18	8
2	48	22	31	17
3	43	40	28	31
4	29	43	18	34
5	7	13	5	10
Totals	155	128		

lead him to conclude, as have Taylor and Nathanson,²⁵ that the size of the initial lesion is the largest single factor in the prognosis. It is therefore not surprising that Taylor and Nathanson find that 41 per cent of 170 treated cases had a local cure for five years. Levin and Clarke²⁸ give the same figure. This represents in both series the summary of all forms of surgical attack on the local lesion and not that of radical vulvectomy.

Inasmuch as patients rarely die of remote metastases, the question arises why a higher percentage

Taussig,³ and Norris and Block⁶ have been recent contributors

Perhaps one should adopt the attitude of Norris and Block⁶ toward prophylactic vulvectomy. These authors write

Physiologic atrophy of the vulva predisposed to pathology. The sequence of events would be the development of minute cracks in this early traumatized atrophic area, followed by infection, itching, more trauma through the years, to the final stage of chronic atrophic dermatitis manifest by a smooth, glistening, translucent parchment-like skin in which the pruritus may be intermittent.

In this group vulvectomy is advised.

Taussig³ found the following possible etiologic factors in the development of carcinoma of the vulva among 155 cases: leukoplakia, 72 cases; syphilis or postsyphilitic vulva, 9; senile warts, 8; Bartholin's abscess, 4; urethral caruncle, 3; trauma, 3; and no lesion, 58. He makes the following recommendations, based on the suggested etiologic factors, concerning prevention of the disease: complete vulvectomy for leukoplakia, with a rigid follow-up; intensive antisiphilitic treatment in tertiary lesions of the vulva, especially in Negresses; removal of warts on the vulva in the postmenopausal age; close observation or excision of enlarged Bartholin's glands after the age of forty; and cautery excision or radium treatment of urethral caruncles.

Estrin Therapy

The use of estrogens, particularly for the pruritus frequently accompanying kraurosis, has become widespread. Taussig³ points out that although estrin therapy may decrease pruritus, a carcinogen may be dangerous on a precancerous leukoplakic base where the underlying pathologic state is one of hypertrophy. It is obvious that in view of the existing confusion on the question whether kraurosis and leukoplakia coexist or are one and the same process, estrin therapy has frequently been used for leukoplakia. Rust,¹⁴ Buxton,¹⁵ Foss,¹⁶ Klawns,¹⁶ and Finkler and Marks¹⁷ report a high percentage of cures, whether the estrogens are applied locally as a salve, rectally in the form of suppositories or parenterally as injections. Savill,⁴ however, believes that most cases are relieved and not cured. The success or failure of the treatment is based on relief obtained from pruritus and burning. Savill thinks that kraurosis of itself has no symptoms and that the pruritus is but a manifestation of infection. Symptoms recur when the infectious foci again become active. Thus, estrin may be said to relieve symptoms, but the improvement is transitory, and moreover its use in leukoplakia vulvitis may be regarded as dangerous.

TREATMENT OTHER THAN RADICAL SURGERY

Radiation

Radiation therapy, either by application or by local infiltration of radium needles or by generalized

x-ray treatment centered over the vulva, has recently been evaluated. The reports are universally discouraging. All writers agree that the worst examples of inexcusable delay, mistaken diagnosis and faulty treatment occur in the treatment of carcinoma of the vulva.

Local Lesion

When a diagnosis of malignant tumor of the vulva, at any age, whether or not ulcerated has once been established by biopsy, a wide vulvectomy, including the perianal skin, should be performed either by

and the dissection is continued laterally. By blunt dissection and retraction the deep epigastric vessels are exposed at the point where they form the medial border of the internal ring. Exposure and ligation of these vessels close to their point of origin is the secret of the entire dissection. It is then possible to reflect the abdominal wall with the round ligament to expose the peritoneum bulging into the iliac fossa. The extent to which the peritoneum may be reflected, giving access to all the retroperitoneal structures in relation to the great vessels, is limited only by the obesity of the patient. The dissection is begun high up. The ureter is found lying medially on the peritoneum. The femoral nerve is identified near the ligament, running laterally to join the femoral vessels. The obturator nerve is found readily in the obturator space laterally.

Starting from above and laterally, the dissection proceeds as the tissue is mobilized medially and downward in relation to the iliac vessels. The obturator nodes are found in the space lying on the obturator internus muscle in association with the obturator nerve. Near the stump of the epigastric vessel nodes are found from the lateral side of the artery to the medial side of the vein, where the external iliac nodes are oftenest involved. The dissection is completed by freeing the tissue medial to the vein in the femoral canal.

The wound is reconstructed, irrigated with saline solution and closed without drainage. The defect in the femoral canal is closed by suturing pectineus fascia to the inguinal ligament. The skin is trimmed to permit a tight closure of the wound without drainage. Pressure dressings are firmly applied, the lower leg is bandaged, and the leg is immobilized for ten days. If at the first dressing serum has collected, it may be aspirated with a syringe and needle. By following this simple procedure the necrosis of the skin edges of the incision observed by Taussig in 90 per cent of his cases has been reduced to a minimum.

bilateral metastases are most evident. Taylor and Nathanson, for example, discovered only 10 per cent bilateral metastases with a unilateral primary lesion, but 27 per cent when the primary disease included or approached the midline. When the size of the initial growth on the vulva is combined with high malignancy and long duration, regional metastases may be expected. In this regard ulcerating lesions are more prone to extend distantly than are papillary lesions, for the latter are by and large of a lower grade of malignancy.

Taussig also believes that the presence of metastasis is of less importance than the size of the primary lesion. His percentage of cures was 11 per cent less in cases with metastases than in those without metastases, whereas lesions greater than 4 cm in size showed 50 per cent fewer cures than the earlier or smaller growths. He further concludes that if a bilateral radical groin dissection is done, the difference between metastatic and nonmetastatic cases measured in terms of five-year survivals is only 11 per cent.

The nodes chiefly involved are the superficial femoral nodes below Poupart's ligament. The secondary spread is by the deep lymphatic nodes to the deep femoral nodes (Rosenmüller's or Cloquet's nodes) or by the inguinal nodes to the external iliac region. It is the latter group that are not touched in the usual superficial groin dissection. Taussig found that in the cases of his series in which the lymph nodes were actually removed, 66 per cent showed involved nodes when a one-sided or superficial operation was done. In the less advanced cases in which a complete radical groin dissection was performed, 41 per cent had metastatic nodes. It is interesting to consider Taussig's five-year survival rate in the light of the above. In the cases in which unilateral or superficial nodes alone were removed there were five-year survivals in only 28 per cent, as against 58 per cent for the more radical, complete dissection.

Moreover, nodes are also found in the obturator space and along the external iliac. The iliac nodes are frequently involved when the lesion is situated along the clitoris.

Where partial or complete removal of the nodes was done, Taussig found 48 per cent of the nodes involved in 95 cases, Taylor and Nathanson found 50 per cent involved in 33 cases.

Inasmuch as Taussig often chooses to perform radical vulvectomy and bilateral radical groin dissections in one stage, the operation is not without its mortality. Age has a direct bearing, for whereas such operations were performed on 45 women under the age of sixty-five with a 2 per cent mortality, operations of the same type in 23 women over sixty-five yielded a mortality of 18 per cent. Vulvectomy alone has an appreciable mortality in the elderly, and 4 of 22 such patients, all over seventy-two years old, died as a result of this procedure. Pos-

sibly the mortality figure for the complete operation can be further reduced if staged procedures are performed.

Operative technic. Taussig's modification of the original Basset operation has been adequately described in the literature. Johnston²⁹ has recently published a further modification for use in the elderly group.

Recently at the Massachusetts General Hospital and at the Pondville Hospital a simple technic for the exposure of the nodes above Poupart's ligament has been routinely employed. This has been described by Taylor and Nathanson²⁵ but has not otherwise been reported. The groin dissection is followed by an attack on the nodes both below and above Poupart's ligament. The advantage of this procedure lies in the excellent exposure and wide vision obtained as high along the iliac veins or as deep in the pelvis as one cares to go. Excellent direct vision of the obturator space is also obtained. All these are secured by the Bassett procedure described in the textbooks, but the repair of the inguinal ligament after section is formidable. The following procedure accomplishes the exposure without division of the inguinal ligament.

Spinal or gas, oxygen and ether anesthesia is given, depending on the age and general condition of the patient. Local anesthesia is rarely used.

The patient is placed with the leg externally rotated and the feet elevated. A straight incision, with the edges beveled outward, is made over the course of the femoral artery across the inguinal crease and carried halfway to the umbilicus, curving toward the anterior spine if one so desires. The extent of the exposure depends in part on the obesity of the patient but more on the extent of the lateral incision through the external oblique fascia — hence the lateral curve.

The dissection is carried out with a sharp knife down to the muscles beyond the saphenous triangle. The saphenous vein is ligated at the lower angle. The fat, nodes and areola tissue along the great vessels are dissected centrally, the large vessels are identified, and the contributing branches are ligated up as high as the point at which the saphenous enters the femoral vein. The femoral canal is dissected clean, including the areola tissue that fills it. By going above Poupart's ligament and removing the fat and nodes overlying the external oblique muscle a bloc dissection of the entire superficial system is accomplished. The skin of the lower portion of the wound is closed without drainage after thorough irrigation. This marks the end of the superficial portion of the dissection and follows the standard procedure.

In the radical portion of the dissection, the external oblique fascia is incised over the course of the inguinal canal as in a herniotomy, and the round ligament is lifted from its bed, exposing the conjoined tendon. This is divided to the internal ring.

where he was finally regulated at 40 units of protamine zinc insulin and 15 units of regular insulin daily and a high-carbohydrate, low-sodium diet.

Second admission (one month later) The patient did well until seven days before entry, when he developed a sore throat and increasing weakness. He also had a dizzy sensation when he bent over. Five days before entry he noticed increasing anorexia and a sharp, constant pain in the right upper quadrant of the abdomen. He had not been drinking much fluid during that time, and his urinary output gradually decreased. The urine also became quite dark in color and gave positive tests for sugar and albumin. He had no dyspnea or orthopnea.

On examination the patient showed a great increase in the slate-gray pigmentation of his skin, with a cyanotic hue, especially marked over the upper chest, arms and face. His face, which had been thin and drawn on the previous admission, was puffy and swollen. The veins of the neck and right arm were strikingly distended. The scleras were muddy. The throat was slightly injected. The chest showed signs of bilateral pleural effusion, and occasional crackling rales were heard at the bases. The heart signs had not changed since the first admission. The abdomen showed marked ascites making palpation difficult, but the liver edge was felt 10 cm. below the costal margin in the mid-clavicular line. There was slight ankle edema. The patient was able to lie quite flat in bed without dyspnea.

The temperature and respirations were normal. The pulse was 94. The blood pressure was 130 systolic, 80 diastolic.

Examination of the blood revealed a red-cell count of 4,000,000, with 11 gm. of hemoglobin. The white-cell count was 15,000, with 66 per cent neutrophils and 30 per cent lymphocytes. The blood sugar was 126 mg. per 100 cc., rising to 364 mg. the next day. At that time the nonprotein nitrogen was 62 mg. per 100 cc. and the carbon dioxide 22.5 milliequiv. per liter. The total protein was 7.0 gm. per 100 cc. with an albumin-globulin ratio of 1.03. The urine showed a green test for sugar and a trace of albumin, but no acetone. The specific gravity was 1.020. The venous pressure in the right arm was equivalent to 340 mm. of water.

An x-ray examination of the chest revealed that since the last examination the diaphragms had become elevated, and this may have accounted for the increase in the size of the cardiac shadow. The cardiothoracic ratio was now 17.5:28.0. The superior mediastinum was somewhat wide. The right leaf of the diaphragm was obscured by irregular areas of increased density in the lung fields, which were probably platelike areas of atelectasis. There was a little fluid in the right pleural sinus.

On the second hospital day, the patient showed pitting edema of the legs up to the knees. Despite penicillin and x-ray therapy to the upper medias-

tinum at the rate of 200r per day for four days, he continued to go downhill rapidly and gradually lapsed into stupor.

An electrocardiogram on the fourth hospital day showed a normal rhythm at a rate of 75, with right-axis deviation. The PR interval was 0.17 to 0.18 second. S_1 and S_2 were prominent. T_1 was upright. T_2 was low upright, and T_3 slightly inverted. CF_2 and CF_4 showed a small R and inverted T. S was prominent in CF_4 . There was a tendency to low amplitude in all leads.

The patient died on the fifth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. WALTER BAUER: The lesion on the nose was evidently a tertiary lesion of syphilis, which disappeared following the administration of potassium iodide.

"He drank a large amount of water and had a urinary frequency of twelve times a day." This is the first suggestion that the patient had hyperglycemia and glycosuria.

Did anyone ever feel the spleen in this patient?

DR. TRACY B. MALLORY: It is not recorded.

DR. BAUER: Despite his difficulty in walking, unsteadiness and not knowing where his feet were, the Romberg and Babinski signs were negative. Is anything said about his eyes? Did he have Argyll-Robertson pupils or any other neurologic abnormality?

DR. JOHN B. STANBURY: All neurologic findings were normal.

DR. BAUER: Is the value of 126 mg. in the insulin-tolerance test higher than one would expect, or is it within normal limits?

DR. STANBURY: It shows insulin sensitivity.

DR. BAUER: But not insulin resistance.

DR. STANBURY: That is correct.

DR. BAUER: It is obvious that in studying this patient an attempt was made to rule out Addison's disease, as well as to gain evidence that hepatic impairment was present. The accumulated information indicates that he had hyperglycemia, glycosuria and hepatic impairment.

The heart was 13.7 cm. to the left. Did he have fairly marked ascites?

DR. STANBURY: Yes.

DR. BAUER: So that the cardiac enlargement was thought to be due to displacement?

DR. STANBURY: We thought that he had cardiac enlargement.

DR. BAUER: I am told that the first electrocardiographic findings are consistent with coronary disease and pericarditis but might be found in other conditions. Evidently they did not persist, as shown by the next electrocardiogram.

Was the diabetes reasonably well controlled?

DR. STANBURY: Quite well controlled without difficulty.

CASE 32261

PRESENTATION OF CASE

First admission A forty-six-year-old Lithuanian-American machinist entered the hospital because of fatigue, weakness and abdominal pains not related to meals.

At the age of twenty-two years the patient had a penile lesion and discharge, which were cleared up by his physician. He had no rash and was well until eight years before entry, when an ulcerating, crusted, thickening of the skin appeared on the side of his nose. This lesion brought him to the Skin Out Patient Department, where blood Hinton and Wassermann tests were positive and the spinal-fluid findings were negative. The lesion regressed under potassium iodide therapy. Six years before entry he received bismuth injections for four months. He then lapsed in his treatments, and was not seen until three years before entry, when he was sent in by the Selective Service Board because of a positive serologic reaction. He then received a total of eight arsenic and thirty-seven bismuth injections, when treatment was stopped because of jaundice. At that time he also complained of weakness, nervousness, exertional dyspnea and epigastric pain. Physical examination revealed a blood pressure of 140 systolic, 110 diastolic, tremor of the tongue and fingers, an aortic systolic murmur and slight midepigastric tenderness. The liver edge was 2 cm. below the costal margin. He was placed on a high-carbohydrate diet and felt improved. During the year before entry he received 10 more bismuth injections. Five months before entry he again noticed increasing weakness, fatigue and occasional pains in the lower abdomen, particularly before bowel movements. He also complained of unsteadiness in the dark and a sensation of not knowing where his feet were. He lost about 8 pounds during this period, despite increased appetite.

The patient admitted drinking two or three quarts of ale a day and whisky occasionally. On one occasion he was seen in the Out Patient Department during an attack of delirium tremens. He drank a large amount of water and had a urinary frequency of twelve times a day.

On examination, the patient appeared chronically ill and showed evidence of recent weight loss. There was a questionable faint slate-gray pigmentation of the skin over the entire body. The heart border was percussed 13.7 cm. to the left of the midclavicular line, with the point of maximum impulse in the fourth interspace. A Grade I systolic murmur was heard at the apex and in the aortic area. The lungs were clear. The abdomen was distended, and a fluid wave obtainable. The liver edge was palpable 7 cm. below the xiphoid process and 3 cm. below the costal margin; the liver was hard and slightly tender. There was also tenderness in the right lower quadrant. There was a general hyporeflexia. Romberg and Babinski tests were negative.

The temperature, pulse and respirations were normal. The blood pressure was 128 systolic, 80 diastolic.

The urine showed a brick-red test for sugar and a +++ test for acetone. A potassium ferrocyanide test for hemosiderin was negative.

Examination of the blood revealed a red-cell count of 3,700,000, with a hemoglobin of 11.9 gm., and a white-cell count of 5900, with a normal differential. The fasting blood sugar was 288 mg. per 100 cc. The carbon dioxide was 28 milliequiv. and the chloride 90 milliequiv. per liter. The sodium was 137.0 milliequiv. per liter. The nonprotein nitrogen was 20 mg., the phosphorus 3.0 mg., the alkaline phosphatase 3.2 units, and the total protein 6.15 gm. per 100 cc., with an albumin-globulin ratio of 1:1. The insulin-tolerance test, starting at 206 mg. glucose per 100 cc., showed reduction to 126 mg. in two hours. A Wilder test for adrenal insufficiency* was negative. The van den Bergh reaction was 0.8 mg. direct and 1.2 mg. total. The cephalin-flocculation test was +++ in forty-eight hours. The bromsulfalein test showed 22 per cent retention. The blood Hinton test was positive. The 17-ketosteroid excretion was 1.8 mg. in twenty-four hours. The spinal-fluid Hinton reaction was positive, but Pandy and gold-sol tests and the cell count were normal. The stool was guaiac positive in two out of four specimens taken. A potassium ferrocyanide skin test and biopsy of the skin were negative for hemosiderin.

X-ray examination of the chest revealed areas of increased density at both bases. The heart was not remarkable. A gastrointestinal series was negative. A cardiogram showed a normal rhythm at a rate of 100, with left-axis deviation. The PR interval was 0.13 to 0.14 second. T₁ and T₂ were flat, and T₃ slightly inverted. TCF₂ and TCF₄ were inverted, and TCF₃ was diphasic.

The patient improved somewhat on a diabetic regime. On the tenth hospital day he developed slight ankle edema, which persisted. He was discharged after twenty days to the Diabetic Clinic.

*Cutler, H. H., Power, M. H., and Wilder, R. M.: Concentrations of chloride, sodium and potassium in urine and blood: their diagnostic significance in adrenal insufficiency. *J. A. M. A.* 111:117-122, 1938.

where he was finally regulated at 40 units of protamine zinc insulin and 15 units of regular insulin daily and a high-carbohydrate, low-sodium diet.

Second admission (one month later) The patient did well until seven days before entry, when he developed a sore throat and increasing weakness. He also had a dizzy sensation when he bent over. Five days before entry he noticed increasing anorexia and a sharp, constant pain in the right upper quadrant of the abdomen. He had not been drinking much fluid during that time, and his urinary output gradually decreased. The urine also became quite dark in color and gave positive tests for sugar and albumin. He had no dyspnea or orthopnea.

On examination the patient showed a great increase in the slate-gray pigmentation of his skin, with a cyanotic hue, especially marked over the upper chest, arms and face. His face, which had been thin and drawn on the previous admission, was puffy and swollen. The veins of the neck and right arm were strikingly distended. The scleras were muddy. The throat was slightly injected. The chest showed signs of bilateral pleural effusion, and occasional crackling rales were heard at the bases. The heart signs had not changed since the first admission. The abdomen showed marked ascites making palpation difficult, but the liver edge was felt 10 cm. below the costal margin in the mid-clavicular line. There was slight ankle edema. The patient was able to lie quite flat in bed without dyspnea.

The temperature and respirations were normal. The pulse was 94. The blood pressure was 130 systolic, 80 diastolic.

Examination of the blood revealed a red-cell count of 4,000,000, with 11 gm. of hemoglobin. The white-cell count was 15,000, with 66 per cent neutrophils and 30 per cent lymphocytes. The blood sugar was 126 mg. per 100 cc., rising to 364 mg. the next day. At that time the nonprotein nitrogen was 62 mg. per 100 cc. and the carbon dioxide 22.5 milliequiv. per liter. The total protein was 7.0 gm. per 100 cc. with an albumin-globulin ratio of 1.03. The urine showed a green test for sugar and a trace of albumin, but no acetone. The specific gravity was 1.020. The venous pressure in the right arm was equivalent to 340 mm. of water.

An x-ray examination of the chest revealed that since the last examination the diaphragms had become elevated, and this may have accounted for the increase in the size of the cardiac shadow. The cardiothoracic ratio was now 17.5:28.0. The superior mediastinum was somewhat wide. The right leaf of the diaphragm was obscured by irregular areas of increased density in the lung fields, which were probably platelike areas of atelectasis. There was a little fluid in the right pleural sinus.

On the second hospital day, the patient showed pitting edema of the legs up to the knees. Despite penicillin and x-ray therapy to the upper medias-

tinum at the rate of 200r per day for four days, he continued to go downhill rapidly and gradually lapsed into stupor.

An electrocardiogram on the fourth hospital day showed a normal rhythm at a rate of 75, with right-axis deviation. The PR interval was 0.17 to 0.18 second. S_1 and S_2 were prominent. T_1 was upright, T_2 was low upright, and T_3 slightly inverted. CF_2 and CF_4 showed a small R and inverted T. S was prominent in CF_3 . There was a tendency to low amplitude in all leads.

The patient died on the fifth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. WALTER BAUER: The lesion on the nose was evidently a tertiary lesion of syphilis, which disappeared following the administration of potassium iodide.

"He drank a large amount of water and had a urinary frequency of twelve times a day." This is the first suggestion that the patient had hyperglycemia and glycosuria.

Did anyone ever feel the spleen in this patient?

DR. TRACY B. MALLORY: It is not recorded.

DR. BAUER: Despite his difficulty in walking, unsteadiness and not knowing where his feet were, the Romberg and Babinski signs were negative. Is anything said about his eyes? Did he have Argyll-Robertson pupils or any other neurologic abnormality?

DR. JOHN B. STANBURY: All neurologic findings were normal.

DR. BAUER: Is the value of 126 mg. in the insulin-tolerance test higher than one would expect, or is it within normal limits?

DR. STANBURY: It shows insulin sensitivity.

DR. BAUER: But not insulin resistance.

DR. STANBURY: That is correct.

DR. BAUER: It is obvious that in studying this patient an attempt was made to rule out Addison's disease, as well as to gain evidence that hepatic impairment was present. The accumulated information indicates that he had hyperglycemia, glycosuria and hepatic impairment.

The heart was 13.7 cm. to the left. Did he have fairly marked ascites?

DR. STANBURY: Yes.

DR. BAUER: So that the cardiac enlargement was thought to be due to displacement?

DR. STANBURY: We thought that he had cardiac enlargement.

DR. BAUER: I am told that the first electrocardiographic findings are consistent with coronary disease and pericarditis but might be found in other conditions. Evidently they did not persist, as shown by the next electrocardiogram.

Was the diabetes reasonably well controlled?

DR. STANBURY: Quite well controlled without difficulty.

DR. BAUER Can you describe the slate-colored pigmentation in more detail?

DR. STANBURY The striking feature in this patient was the pigmentation. When he first came in he had a faint slate-gray pigmentation, most marked in the thorax and the face. There was some argument about it. At the second admission, two months later, we thought that the pigmentation had increased, extending over the lower part of the body. In addition the upper extremities and face had almost black cyanosis. It was a very striking picture.

DR. BAUER And "slate gray" is the best description you can give?

DR. STANBURY Yes.

DR. BAUER This man has evidence of obstruction of the superior vena cava, probably in the region of the right innominate artery, without associated symptoms. The physician in charge must have thought the patient had some type of infection because penicillin was administered, the temperature was normal, however.

The white-cell count was not unlike that seen in many patients with cirrhosis of the liver, 5000, yet it later rose to 15,000.

The superior mediastinum was somewhat wide. I should like first to see the x-ray films of his chest.

DR. JAMES R. LINGLEY I cannot add anything to the record. This film shows a high diaphragm, which caused the apex to be pushed out slightly, but I doubt that the heart was enlarged at that time. There are bands of density at both bases, perhaps due to partial atelectasis of the lower lobe. This film two months later shows what I think is an actual increase in the size of the heart, despite the high position of the diaphragm.

DR. BAUER Is it consistent with atelectasis?

DR. LINGLEY More so than with effusion, because the outline is preserved. There are increased density, atelectasis at both bases and fluid in the right costophrenic angle.

DR. BAUER What can you say about the mediastinum?

DR. LINGLEY I think that it is probably wide because of the position of the diaphragm, the great vessels being spread out over a greater area.

DR. BAUER I thought it fair to assume that this man had contracted syphilis at the age of twenty-two, and that antisyphilitic treatment was not given until the appearance of a tertiary lesion. It also seems fair to conclude that he had never been adequately treated. It is rather difficult to avoid diagnosing central-nervous-system syphilis, probably tabes dorsalis, on the basis of the symptoms and the positive Hinton test on the spinal fluid. I suppose that the latter was relatively inactive or a burned-out process.

In addition this man exhibited obvious hepatic enlargement and ascites. Hepatic impairment was present as demonstrated by all the tests employed. There were also hyperglycemia and glycosuria. I

prefer to explain these findings on the basis of hemochromatosis, despite the negative skin biopsies. One might rightly argue that this man had been exposed to any number of agents that could have injured his liver. He developed jaundice while receiving arsenic. Whether this was an arsenical hepatitis or a coincidental infectious hepatitis, one cannot determine. If it was infectious hepatitis, could it possibly have been syringe transmitted? He also gave a history of excessive alcoholic intake, which is commonly found in people with cirrhosis of the liver, and last, but not least, he had syphilis, which can also cause liver disease. The description of the liver is not that of gumma of the liver. I prefer to try to tie things together in the manner already stated, namely, that the hepatic disease, the glycosuria and the hyperglycemia were part and parcel of hemochromatosis. Between the first and second admissions he developed what I should interpret to be obstruction of the superior vena cava, probably at the junction of the right innominate vein because the findings were more marked on the right than on the left. This, as I said before, came on without any symptoms, so I think that it is reasonable to assume that he did not have a mediastinal tumor. He probably had an idiopathic thrombosis of the superior vena cava, which, though rare, can occur. If one entertains that diagnostic possibility one might ask whether this man had an ascending thrombosis of the vena cava, which first became evident when impaired venous return from the head, neck and right arm was noted. I should think that that was rather unlikely in view of the fact that the physical examination does not suggest findings of the type we expect to encounter in a man with a gradually ascending thrombus of the vena cava.

There is one finding that I have not explained namely, the cardiac enlargement. He never exhibited the signs of aortic regurgitation. There have been a few cases of myocarditis reported as being due to hemochromatosis, and such an explanation might apply in this case. I am well aware, however, that it is exceedingly rare. In concluding I shall say that we are dealing with a man who had syphilis, which was never treated properly. He probably had central-nervous-system syphilis, which was quiescent or burned out. In addition, he had hemochromatosis and obstruction of the superior vena cava, the exact cause of the latter I do not know, but I do not believe that it was due to a mediastinal tumor. I assume that this man went into coma of the type that is seen in hepatic insufficiency, although the record is not too clear on this point.

I should gladly receive suggestions or comments. Dr. Richardson, do you want to help me?

DR. WYMAN RICHARDSON I am keeping quiet.

DR. BAUER I have often told Dr. Mallory that these conferences would test our diagnostic acumen more accurately if he handed one of us the record.

and asked us to discuss it, instead of giving it to us several days in advance. I am glad this system was not in effect today. Although I have read this case abstract four times, I am not absolutely certain of my interpretation. For instance, I failed to mention the symptoms referable to the bowel and the finding of the two positive guaiac tests. One might argue that we had overlooked a malignant lesion of the bowel that finally metastasized to the mediastinum. This is possible, the clinical picture, however, is complicated enough, and I prefer to limit my discussion to the above possibilities.

A PHYSICIAN: What about the possibility of pericardial effusion to account for the cardiac enlargement?

DR. BAUER: I gather that the margins were too distinct for a pericardial effusion. The x-ray picture is more like cardiac enlargement due to myocarditis.

DR. CHESTER M. JONES: With chronic hepatic disease and hepatic insufficiency, do you not believe that abdominal pain and leukocytosis are not infrequent at that stage of the game? The white-cell count of 15,000 is not unusual. As a matter of fact I have often seen leukocytosis in certain phases of liver disease.

DR. ISAAC M. TAYLOR: What about beriberi?

DR. BAUER: I am sure that the terminal cardiac enlargement is consistent with beriberi. I prefer to tie things together in this case, however. I might include other conditions, such as syphilitic myocarditis and syphilitic liver disease, but I think that is making it much too difficult.

DR. J. H. MEANS: Are you interested in the body hair?

DR. BAUER: Yes, I should like to know about it. I should also like to know about the prostate. I assume that Dr. Mallory will tell us about these, as well as other things.

I am still disturbed that the pigmentation is spoken of as slate colored and not brownish, but I do not believe that one negative biopsy should scare us out. It may or may not have been done properly. Hemochromatosis is not always demonstrated in the skin, it can be confined to viscera.

DR. MEANS: How about argyria?

DR. BAUER: It sounds more like argyria. That brings another red herring across the path.

DR. BENJAMIN CASTLEMAN: Dr. Joseph C. Aub saw the patient and brought out the idea that if he had cirrhosis on a pigmentation basis perhaps he had developed a hepatoma. Hepatoma is quite prone to extend into and to block the vena cava.

DR. BAUER: That is a good point. I thought of hepatoma last night but not this morning.

DR. JONES: This would be an ideal case for an inspiration biopsy of the liver.

DR. MALLORY: One was done.

DR. BAUER: I am glad that I did not know about it.

DR. MALLORY: We thought that we should let Dr. Bauer have the pleasure of discussing the case without knowing the answer.

As a matter of fact, when the iron reaction was performed on the biopsy specimen the liver cells and also those of the bile-duct epithelium showed blue granules, a characteristic picture of hemochromatosis.

CLINICAL DIAGNOSIS

Hemochromatosis

DR. BAUER'S DIAGNOSES

Hemochromatosis

Obstruction of superior vena cava

Tertiary syphilis

Central-nervous-system syphilis, probably tabes dorsalis

ANATOMICAL DIAGNOSES

Hemochromatosis, generalized, including liver, pancreas, lymph nodes, thyroid and pituitary glands and heart

Cardiac hypertrophy with marked dilatation

Mural thrombus of right auricle

Ascites

Splenomegaly

Hydrothorax

Esophageal varices

Thrombosis of right cephalic vein

PATHOLOGICAL DISCUSSION

DR. MALLORY: At autopsy we found a considerably enlarged liver, weighing 2380 gm. It was dark chocolate brown. The lymph nodes in the hilus were equally dark brown, as were the pancreas and heart.

All of them were full of hemosiderin. Microscopically it was evident that the thyroid, adrenal and pituitary glands were involved. It is rather characteristic of hemochromatosis that pigment deposits are quite marked in most of the endocrine organs. The heart was dilated and extremely flabby, but showed no microscopic abnormality other than moderately severe iron deposits. At autopsy we did not find a thrombosis of the superior vena cava or any of its large tributaries. The right cephalic vein contained a recent jelly-like, dark-red clot, which was not attached to the intima and which extended distally from its termination in the axillary vein for about 5 cm. That seems to explain the distention of the veins in the right arm but not those in the head and neck. There was a thrombus in the right auricular appendage, but I doubt that it was large enough to have caused obstruction at the orifice of the vena cava. Consequently we are left without an explanation for the apparent upper mediastinal syndrome.

DR. JONES: Occasionally in any case of cirrhosis, particularly with a great deal of fluid, and if the patient is horizontal and the head not elevated, the

face is puffy and there is marked edema, which disappears when the patient is elevated for twelve hours. This patient also had ascites and peripheral edema.

CASE 32262

PRESENTATION OF CASE

A sixty-year-old nurse entered the hospital because of abdominal pain and jaundice.

Ten months before admission the patient experienced an episode of moderate right-upper-quadrant pain and jaundice lasting several days. The icterus quickly faded, but the patient never felt so actively interested in her work or environment after the episode as she had before it and often had intermittent pain and indigestion. During the next ten months she lost about 65 pounds. Three weeks before admission there was a gradual onset of pain in the right upper quadrant of the abdomen and the lower anterior portion of the right chest, associated with severe nausea and vomiting. The pain was aggravated by coughing and respiration. She was seen by a physician, who told her she had gall-bladder disease. A week before admission her appetite failed. On the morning of entry her sister called attention to the yellow color of the scleras. The stools had been yellowish during this illness.

The patient had had diabetes for five years, during which she was on a diabetic diet and took 20 units of protamine insulin daily. She had had a blood pressure of 195 systolic, 90 diastolic for several years, with at least one episode of auricular fibrillation.

On physical examination there was evidence of considerable weight loss. The skin was yellow and dry. There were rales at the bases of both lungs. The diaphragm was high and its excursions diminished on both sides. There was a Grade II apical systolic murmur. The abdomen was distended and tender, particularly in the upper quadrants. A very tender mass filled the right upper quadrant, extending to below the umbilicus. There was also a mass in the left upper quadrant. Peristalsis was diminished. The uterus felt hard and enlarged. No other pelvic mass was palpable.

The temperature was 102.2°F, the pulse 120, and the respirations 27. The blood pressure was 130 systolic, 85 diastolic.

There were 12.5 gm of hemoglobin, and the white-cell count was 6340. The urine had a specific gravity of 1.015. The protein content was + and the sugar reaction green. A foam test revealed bile. The bilirubin was 13 mg per 100 cc direct, 14 mg indirect. The serum amylase on two successive days was 7 units per 100 cc. The fasting blood sugar was 334 mg per 100 cc, the carbon dioxide content 32.2 milliequiv per liter, the nonprotein nitrogen 41 mg and the serum protein 7.8 gm per 100 cc and the chloride 94 milliequiv per liter. The prothrombin time was 43 seconds (normal, 19 seconds).

The chest film was normal, but a flat film of the abdomen showed several moderately distended loops of small bowel. There were unidentifiable collections of gas high in the right upper quadrant and midabdomen, and a mass seemed to be pressing on the lesser curve of the stomach. The liver was large and apparently continuous with the mass compressing the stomach. There was a tendency toward left-axis deviation in the electrocardiogram. The PR interval was 0.13 second. ST₁ was depressed, ST₂ inverted, T₁ diphasic, T₂ slightly inverted, TCF₁ upright, TCF₂ low upright, and TCF₃ slightly inverted.

In the hospital the temperature fell to 98.6°F within twenty-four hours and remained normal or subnormal thereafter. Abdominal distention and tenderness persisted. Peristalsis was seldom audible. A peritoneoscopy was performed on the seventh hospital day. Widespread adhesions fixed the small bowel so that it did not move out of the pelvis in the extreme Trendelenburg position. The right lobe of the liver and the gall bladder were covered by an apparently inflammatory mass including the colon and the small bowel. In the left upper quadrant on the anterior peritoneal surface there were several 2-mm and larger yellow nodules thought to resemble fibrin. The visualized portion of the left lobe of the liver was normal. There were no metastatic implants anywhere. On the day after the operation there was an episode of sudden sharp pain in the right side of the chest. There were dullness and diminished breath sounds at the right lung base. The pulse and respiration rose moderately, and the skin was sweating and cyanotic. Both calves were tender. In the x-ray examination the right leaf of the diaphragm was elevated. The diaphragmatic shadow could not be made out. The right pleural sinus contained fluid, and there was some reaction in the lung above. In addition there was an air-containing cavity just below the right leaf of the diaphragm, apparently above the liver, with a fluid level 5 cm in length. The serum bilirubin had risen to 19 mg per 100 cc direct, 3.1 mg indirect. The fasting blood sugar and prothrombin time had returned to 101 mg per 100 cc and 23 seconds respectively. The chest pain disappeared on the tenth hospital day. On the twelfth hospital day the patient had sudden dyspnea and collapse without pain. The skin was clammy and cyanotic, and the pulse and blood pressure were not obtainable. The percussion note was markedly impaired, and breath sounds depressed over the entire right lower lobe. Loud rhonchi were heard throughout the rest of the lung fields. The neck veins were moderately engorged. The patient died that evening.

DIFFERENTIAL DIAGNOSIS

DR ARTHUR W ALLEN Before Dr Lingley shows us the x-ray films, I should like to be told the number of hours the patient lived after her second episode.

AN INTERVIEW About four hours

DR. JAMES R. LINGLEY These are the first chest films, showing normal lung fields on both sides and only slight elevation of the right diaphragm and no gas beneath it. The plain film of the abdomen, taken at the same time, shows above the dilated loops of the small bowel, gas in the stomach with a pressure defect on the lesser curvature, which I presume is due to the mass referred to. In addition to the gas in the small bowel and stomach there is a gas-filled cavity beneath the lower border of the liver. That collection of gas is definitely outside the duodenum, and I think that it is too high for the hepatic flexure of the colon. These are the later films of the chest taken eight days after the first examination. They show a marked change. The diaphragm on the right is now elevated, and there is this large air-containing cavity immediately beneath the diaphragm. There is probably some collapse of the lower lobe and a little fluid in the costophrenic angle. The same thing is seen in the lateral view. Here is the film taken of the patient lying on her left side and showing a shift of the fluid level to the left flank. In going over these films I thought also that there was some air in the soft tissues of the abdominal wall on each side. That air is outside the abdominal cavity.

DR. ALLEN We have no film of the chest after her second episode, on the day of death?

DR. LINGLEY No.

DR. ALLEN Are you able to see the hard mass in the pelvis in the first film?

DR. LINGLEY There are some areas in the pelvis that suggest calcification in a fibroid.

DR. ALLEN I suppose that this case is being presented not so much for a differential diagnosis of the primary disease as for a discussion of the events regarding the sudden episodes of discomfort and final death. Without any question, the history is consistent with gallstones, and the physician who made that diagnosis was probably right. The weight loss of 65 pounds from the time of the first episode of pain and admission to the hospital is interesting but may be based entirely on dietary restrictions, perhaps self-imposed because of indigestion and pain with a normal diet.

The three weeks' duration of the illness that brought the patient to the hospital is consistent with the period that an inflammatory process in the gall bladder takes to erode the hollow viscus and sometimes to produce a fistulous tract that may allow a gallstone to be discharged into the gastrointestinal tract and to produce gallstone ileus. Associated with that degree of inflammatory reaction is a pericholecystic inflammatory process, which might involve hepatic flexure and some of the small intestines, as the peritoneoscopist observed.

The probable reason that peritoneoscopy rather than exploration was decided on was the fact that

the patient was in a fairly serious condition, the diagnosis was not well established and she had had the acute inflammatory process for three weeks at the time of entry. We have here a finding by the peritoneoscopist of some interesting yellow nodules scattered about, particularly in the left upper quadrant. He thought that these nodules resembled fibrin, and that might be what they were. One wonders whether these may have represented fat necrosis, which is associated with pancreatitis. The serum amylase, which was normal on two successive days at entry three weeks after the onset of an episode of this sort, is consistent with pancreatitis, and in some of the necrotic types of pancreatitis there is a normal serum amylase, so that pancreatitis cannot be ruled out on the basis of these normal determinations.

It is amazing that the diabetes responded so well, in spite of the patient's precarious condition, and that the fasting blood sugar returned to normal so promptly. This is also a good illustration of how rapidly vitamin K can reduce a high prothrombin level to a comparatively normal reading. The mass that was felt was probably more or less over the right upper quadrant. This red herring of a mass that projects into the lesser curvature of the stomach bothers me somewhat but might be consistent with a pancreatic collection in the lesser peritoneal sac, which is not an unusual association of pancreatitis. The air outside the gastrointestinal tract is consistent with a perforation between the gall bladder and the intestinal tract and fits quite well into the picture of an acute or subacute cholecystitis that had produced perforation with a secondary peritonitis. The air seen in the abdomen following the peritoneoscopy is not very impressive, since during peritoneoscopy a great deal of air is pumped into the peritoneal cavity to separate the viscera from the abdominal wall, this does not mean that there was a free perforation into the peritoneal cavity.

The episode of sudden pain and dyspnea on the day after the peritoneoscopy is consistent with an embolic phenomenon. This woman had been ill and in bed for four weeks by the time peritoneoscopy was performed and this so-called "operative procedure" was not necessarily to blame for the embolus. It is quite likely that there was a thrombosis of the leg veins, which was not taken too seriously because the patient had so many other things the matter with her. The record does not state that following this first episode anything was done to interrupt the superficial femoral veins to prevent further emboli. I suppose the fact that it was not recorded means that this was not done. There are no clear signs of infarct that I can make out in these films, because the area that is probably involved, that is, the right lower lobe, is obscured by the high diaphragm and the surrounding reaction in the lung. I do not suppose that Dr. Lingley would be willing

to say that this is typical of infarct from the roentgenologic point of view

DR LINGLEY It looks like collapse, and that degree of collapse is consistent with an infarct

DR ALLEN So often following these episodes of infarction, the roentgenologist is the man who can say without any equivocation that the lesion is an infarct. Of course the common source of emboli is the deep veins of the leg. We have interrupted the veins on approximately 1300 patients in this hospital to prevent emboli and have markedly decreased the number of patients who have had prolonged convalescences. If left alone these early bland thromboses progress to phlegmasia alba dolens in a high percentage of cases in this community. If the vein is opened, the clots aspirated and the veins interrupted, the convalescence is greatly shortened. The patient may have inflammatory processes in the veins afterward, but these are never so severe as when they are not operated on. Also, the hazard is eliminated in nearly all cases of fatal emboli. We do have a small percentage of patients that have infarcts after this procedure, and those are best treated by the anticoagulant drugs and not by further surgery.

In this case, there is a description of an episode that occurred on the twelfth hospital day, five days after peritoneoscopy and four days after the first episode of pain in the chest. This is a fairly good description of another embolism. There are certain facts about it. The fact that she lived four hours after the episode is somewhat unusual, although possible. One would have to seek for some other explanation for sudden dyspnea and collapse, even without pain. With a drop in blood pressure vasomotor collapse does occur rather suddenly and is associated with other conditions, such as peritonitis, ileus, high intestinal obstruction and perforation of the viscus, but as a rule none of these are associated with sudden dyspnea. I do not know whether the sudden dyspnea can be explained on the basis of the heart disease, but my belief is that she had a second embolus, which was probably the final cause of death.

This was a patient with gallstones, diabetes, subacute cholecystitis, perforation of the gall bladder with pericholecystic abscess, localized peritonitis (not too localized, I might add) and pancreatitis. The probabilities of subdiaphragmatic abscess are great, not on the basis of this fluid level but on the basis that fluid would have been present above the liver and beneath the diaphragm with any such inflammatory process in this region, since fluid goes there with any opportunity, probably brought about by the forces of respiration. The patient was found to have some biliary cirrhosis, which was due to the jaundice. Obviously she had heart disease, and finally she had pulmonary emboli.

DR TRACY B. MALLORY This is a very long and complicated story. Are there any other suggestions?

I wonder if any of the surgical house officers can tell us what was thought on the wards.

DR T. H. GREEN, JR. We thought, as Dr. Allen did, that the patient probably had gall-bladder disease and gallstones, that the gall bladder perforated three weeks before entry and that she developed a subdiaphragmatic abscess that eventually penetrated through into the peritoneal cavity. At the last episode there was some question whether it might have been primary heart failure rather than a pulmonary embolus.

DR MALLORY Dr. Stanbury, have you any comment?

DR JOHN STANBURY I saw the patient briefly one night, following her last episode and I thought that she had a pulmonary infarct. I was unaware of what was going on in the abdomen.

CLINICAL DIAGNOSES

Jaundice
Cholecystitis, with cholelithiasis
Perforation of gall bladder
Peritonitis
Subdiaphragmatic abscess
Pulmonary infarcts
Diabetes mellitus

DR ALLEN'S DIAGNOSES

Diabetes
Subacute cholecystitis, with perforation and pericholecystic abscess
Cholelithiasis
Pancreatitis
Subdiaphragmatic abscess?
Pulmonary embolism
Biliary cirrhosis
Jaundice

ANATOMICAL DIAGNOSES

Actinomycotic abscesses of peritoneum and liver, with perforation of right diaphragm
Cholelithiasis and choledocholithiasis
Chronic cholecystitis
Double renal pelvis and ureters
Adrenal hyperplasia, unilateral
Neurofibromas of stomach
Leiomyomas of uterus
Diverticulosis of sigmoid
Healed pulmonary tuberculosis, apical.

PATHOLOGICAL DISCUSSION

DR MALLORY Dr. Allen made about 10 clinical diagnoses, we wound up with a list of 20 anatomical diagnoses. The underlying and most long-standing disease of significance in this patient, I am sure, was gallstones. We found a large stone in the cystic duct, another large one in the common duct, and many smaller ones in the dilated intrahepatic bile passages. The gall bladder was shrunken and shriveled, but was not perforated. We also found a

series of abscesses, one of which was in the pelvis in the general region where the peritoneoscopist had noticed adhesions of the small bowel. Another was beneath the right lobe of the diaphragm, and a third around the spleen beneath the left lobe of the diaphragm. The abscess on the right had perforated through the diaphragm and into the lung. There was also a large abscess within the liver. The peritoneal cavity was free from generalized peritonitis, but there were a number of small yellow spots that had been noted by the peritoneoscopist and described as flecks of fibrin. On incision they were found to contain fluid. On careful examination of that fluid and also of the fluid in the many abscesses, multiple sulfur granules were grossly evident—in other words, actinomycosis. There were no pulmonary emboli, and we have no anatomic explanation of the two episodes of collapse. They may have been associated with sudden extensions

of the infection, such as rupture of the liver abscess into the subdiaphragmatic space and extension through the diaphragm. Among many other anatomic landmarks, this patient had double pelves and ureters in both kidneys, a rather large adenomatous hyperplasia of one adrenal gland, fibroids of the uterus, multiple small neurofibromas of the stomach, some healed pulmonary tuberculosis and generalized diverticulosis of the sigmoid colon.

DR. ALLEN: What was the mass displacing the stomach? Was that an abscess?

DR. MALLORY: That was an abscess, mostly intra-hepatic, not perihepatic.

DR. ALLEN: I recall one patient who had a perforation of the diaphragm following a subdiaphragmatic abscess associated with perforated duodenal ulcer and who went into collapse and died in a manner not unlike this one in about the same number of hours.

THE STAFF OF LIFE

THE United States, according to the June *News Letter* of the Department of Agriculture, is failing to meet its commitments in the export of foods to famine-stricken countries. We failed to meet our goal for both grain and fats and oils during the first quarter of the year and that for grain in April, and the 80 per cent flour-extraction program will save only 15 to 20 million bushels of wheat instead of the 25 million expected. The 30-cent bonus per bushel offered for wheat delivered before May 25 has, however, encouraged farmers to make their stocks available, and wheat has begun to move. Still, to accomplish our aims, the production of flour for domes-

tic use must be cut to 75 per cent of the May and June distribution of last year. Distillers have already been limited to three days' operation a month, and the use of grain in feeding livestock has been drastically cut. For the first time in our history, bread has literally assumed its allegorical importance and has become the staff of life.

Whether productive countries and countries whose economic affairs are conducted on a reasonably progressive plane should attempt the obviously impossible task of feeding those whose population increases are far beyond their capacities to support is a debatable matter. The question of tiding our usually self-supporting neighbors over a period of famine caused by such unnatural circumstances as a world war is something else, we are bound to a special type of obligation. And yet it seems to be a fact that, despite all publicity up to the present time, the people of this country are confused regarding their obligations, are uninformed on the sacrifices necessary to discharge them and have found, unfortunately, no reason for believing that their guides in these important matters are themselves particularly well informed.

During the war, when general food rationing was in effect, many of us frequently knew about where we stood on the problem of balancing our diets, we were bound to a common cause and knew what to expect in the performance of our tasks. Now, in the peace that literally passeth all understanding, we are beset by more difficulties than we encountered during the war, except that of the war itself.

Good leadership, in an enlightened country, should be a leadership that further enlightens those who are willing and need to be led. We are disturbed, not because we want more than we are getting, but because we want to know the reasons why certain things are lacking, and we want those reasons to be good. We want to know why meat is scarce, and if it is because 90 per cent is going into the black market, we want to have something done about it.

During the past years when butter became difficult to obtain because of our large armed forces, we used oleomargarine and liked it. Now that we can get neither butter nor oleomargarine, we are troubled because we are afraid that bread is being withdrawn so that we shall not miss the butter that

we cannot get to put on it. We are willing to play along with the Magi, but we should like to know that they know the answers, and that the answers do not change too often.

THE CHANGING POTENCY OF COMMERCIAL PENICILLIN

MANY physicians who have been using penicillin in the treatment of serious infections have become aware of the increasing doses required to accomplish the therapeutic results that they have become accustomed to expect. This has been compensated for, in part, by the greater availability of the product and by an increase in its purity, the latter having made possible the injection of large numbers of units in small volumes, with a decrease in the amount of irritation experienced from the injections. The decline in the effectiveness of commercial penicillin has been statistically quantitated so far as the treatment of syphilis is concerned, and it has been shown that the results of penicillin treatment of early syphilis have been distinctly less satisfactory since May, 1944, than prior to that date.¹ The reason for this change has been shown unmistakably to be an alteration in the character of the commercial preparations of penicillin.² Recent products have also been found to be less effective in the treatment of experimental pneumococcal and streptococcal infections.³

It is known that commercial penicillin contains at least four molecular species identified as F, G, K, and X, which differ from each other only in the nature of the side group attached to a common nuclear structure.⁴ These forms of penicillin vary significantly in their antibacterial activity in vitro. Until recently therapeutic activity has been found in general to parallel in-vitro activity. Eagle and Musselman³ discovered, however, that the activity of penicillin K in experimental infections of animals did not parallel the activity of this species of penicillin in vitro. The basis for this discrepancy was the rapid drop in blood levels and the small urinary recoveries after a given dose of penicillin K, as compared with that of penicillin G, at any time after an injection of a specified amount of various forms of penicillin, the levels of penicillin K were much lower than those observed with the other

penicillins, and penicillin K persisted at any given level for much shorter periods. In both rabbits and man the recovery of penicillin K in the urine averaged 30 to 35 per cent. This compares with an average recovery for penicillins F, G and X of 74 per cent in rabbits and 91 per cent in man.

In pneumococcal infections of mice an impure preparation of penicillin K was one-sixth as active as penicillin G (the form that formerly predominated in commercial penicillins) and one-eighth as active as penicillin X. In the treatment of experimental streptococcal infections in mice a pure preparation of penicillin K was one-eleventh as active as penicillin G and one-thirtieth as active as penicillin X. In experimental syphilis in rabbits penicillin K was found to be about one-tenth as effective as penicillin G. These findings suggest that penicillin K is inactivated in the body to a greater extent and more rapidly than are the other forms of penicillin and thus gives a lower therapeutic activity than would be anticipated from its bactericidal action in vitro.

Unfortunately, preparations of penicillin being supplied currently by the majority of the large producers have shown an increasing proportion of penicillin K. Since the number of units represents only the results of titrations in vitro against a single strain of staphylococcus, it is not possible to predict either the proportion of penicillin K or the amount of therapeutic activity that is present in any of these preparations. It seems clear that the amounts of penicillin K in commercial penicillin should be minimized, and it also seems desirable to standardize impure mixtures of penicillin for therapeutic use by some method other than the bactericidal activity in vitro. Until such a method is devised, it is essential to use considerably larger doses of penicillin in the therapy of infections than were formerly considered effective.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

SANDERS — Loren A. Sanders, M.D., of Concord, died April 24. He was in his seventy-second year.

Dr. Sanders received his degree from the New York University College of Medicine in 1899. He was medical referee for Merrimack County and attending surgeon at the New Hampshire Memorial Hospital. He was a fellow of the American College of Surgeons.

His widow survives.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

LIST OF MASSACHUSETTS LABORATORIES HOLDING CERTIFICATES OF APPROVAL

The Department of Public Health has just published its first list of the laboratories in the Commonwealth currently holding certificates of approval, indicating the tests for which each laboratory is approved. Copies have been mailed to all hospital superintendents and chiefs of staff, as well as to the laboratory directors and head technicians of the approved laboratories themselves.

The approval of bacteriologic and serologic laboratories stems from Section 184A of Chapter 111, which was passed in 1939, stating that the Department may at the request of a laboratory issue a certificate of approval for the performance of designated bacteriologic and serologic tests that the Department finds the laboratory capable of performing satisfactorily. Application is voluntary, but laboratories are urged to seek approval for all tests that they routinely perform, not for those done elsewhere.

The approval of a laboratory is determined essentially by the qualifications of its personnel, the suitability of its quarters and equipment, the use of accepted methods, the satisfactory performance of its work and the maintenance of adequate laboratory records. Accuracy of tests is ascertained by ability to maintain close agreement with other laboratories on specimens sent out periodically to approved laboratories by the State Bacteriological and Wassermann laboratories. This is the most important single method for evaluation of a laboratory. From time to time visits are made by a member of the Department to reappraise the laboratory and to make suggestions when desired. A certificate of approval is granted for one year, and renewal is dependent on a continued satisfactory standard.

Chapter 155 of the Acts of 1946 extends the laboratory-approval program to include ordinary blood grouping and Rh blood testing, as well as cross matching of donors and recipients for blood transfusions. In addition, it authorizes the issuance of

certificates of approval for laboratory tests on milk, foods, eating utensils, water and sewage. A list of laboratories approved for these additional tests will be available later.

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	CLINIC CONSULTANT
Haverhill	July 3	William T. Green
Gardner	July 9	John W. O'Meara
(Worcester Sub-clinic)		
Brockton	July 11	George W. Van Gorder
Pittsfield	July 15	Frank A. Slowick
Salem	July 15	Paul W. Hugenberger
Worcester	July 19	John W. O'Meara
Fall River	July 22	David S. Grace
Hyannis	July 23	Paul L. Norton

Physicians referring new patients to clinic should get in touch with the District Health Officer to make appointments.

MISCELLANY

CONSULTATION SERVICE FOR DIAGNOSIS AND TREATMENT OF MALIGNANT TUMORS OF IN- FANCY AND CHILDHOOD

Announcement is made of the establishment of a consultation service to provide assistance in the diagnosis and treatment of tumors of infancy and childhood. This is a further step in the organization of the Children's Cancer Center, a unit of the Medical Center for Children in Boston.

This is not a tumor registry. It is designed, rather, to give without charge immediate diagnostic assistance and advice concerning therapy and prognosis to any doctor who will send the necessary clinical data, microscopic sections and x-ray films. Replies will be given by air mail or, when necessary, by telephone or telegraph. The project, which is supported in part by a grant-in-aid from the National Advisory Cancer Council, will be paralleled by a research program concerning the biology of tumors of early life, together with a consideration of the clinical, pathological and epidemiologic aspects of the problem.

The consultation service will be rendered by a group of three pathologists, Dr. S. Burt Wolbach, Dr. Charles F. Branch and Dr. Sidney Farber, and one roentgenologist, Dr. Edward D. B. Neuhauser, with the co-operation, when indicated, of the entire staff of the Children's Hospital, through the chiefs of the clinical services. Doctors representing all the clinical and laboratory specialties concerned with the infant or child will be available for consultation.

Communications should be sent to Dr. Sidney Farber, Children's Hospital, 300 Longwood Avenue, Boston 15, Massachusetts. The service will begin to function on August first.

CORRESPONDENCE

AMERICAN COMMITTEE FOR YUGOSLAV RELIEF

To the Editor: We medical men know that the work of saving human lives knows no boundaries. The horror of war is over, but the battle for survival is still going on in Yugoslavia. It must be said that disease and death conquer even where the Nazis failed.

During the war, Yugoslavia lost nearly 2,000,000 — 15 per cent of the total population. We make a plea for the living, many of whom are also doomed to die unless you help them. We speak for the 1,487,000 children in desperate need of medical care. We speak for 150,000 known victims of tuberculosis. We speak for 1,000,000 persons infected with malaria. We appeal for their very lives.

Statistics all too frequently dull the imagination, yet we cannot present the medical case of Yugoslavia without them. Please bear in mind that figures denote people and people are suffering. In Macedonia half the population has malaria. In Yugoslavia as a whole, 1 out of 25 has tuberculosis and the death rate from tuberculosis is ten times higher than that in the United States. In prewar Yugoslavia the infant mortality rate was the highest in Europe, with 155 dead for every 1000 living births, as compared with 56 in the United States. Now the infant mortality rate has risen to 170, while in Greater New York it has decreased to 35, in Sweden to 30 and in England to 38.

As against this background of widespread disease and soaring death rates, consider the medical facilities now available to the Yugoslavs. In all of Yugoslavia there are but 12,000 hospital beds. For the 150,000 people with active tuberculosis who require hospitalization, there are only 1500 beds. In mountainous Yugoslavia with its shattered communications there is but 1 doctor to every 5000 people, and in isolated communities it is nearer 1 doctor to every 10,000. Greater New York has 1 physician to 450 persons. Tuberculosis-ridden Yugoslavia has but 2 chest surgeons. These are the figures.

Yugoslavia needs — desperately needs — hospitals, clinics, research laboratories and facilities for training doctors and nurses. The American Committee for Yugoslav Relief, 235 East 11th Street, New York City, is conducting a campaign for \$5,000,000 to provide some part of these medical necessities. We feel sure that the health program of the Committee will meet with warm response. Our land is rich, the will of the people to help, unprecedented, and its generosity, unsurpassed.

BOOK REVIEWS

The History of Surgical Anesthesia. By Thomas E. Keys, M.A. With an introductory essay by Chauncey D. Leake, and a concluding chapter, "The Future of Anesthesia," by Noel A. Gillespie. 8°, cloth, 191 pp., with 43 illustrations. New York: Schuman's, 1945. \$6.00.

This authentic and official history of anesthesia represents a synthesis of five essays and a chronology of anesthesia previously published by the author, well known as reference librarian for the Mayo Clinic. The introductory essay by Professor Leake, of the University of Texas, who developed the use of divinyl oxide, discusses the nature of pain and anesthesia and the discovery of modern anesthetic agents. The body of the text by Major Keys presents a complete history of the development of anesthesia, followed by a chronology of events relating to anesthesiology and allied subjects, with a bibliography of over three hundred references arranged both by subject and by author. Dr. Gillespie's concluding chapter forecasts the further development of the professional anesthetist as a specialist in medicine. An appendix by Dr. John F. Fulton of Yale University, contains his bibliographic study of the Morton and Warren letheon tracts. This authoritative and scholarly work of reference is admirably illustrated by an engraved frontispiece and by forty-five well selected text figures.

Radiologic Examination of the Small Intestine. By Ross Golden, M.D. 4°, cloth, 239 pp., with 75 illustrations. Philadelphia: J. B. Lippincott Company, 1945. \$6.00.

This is an excellent monograph by a highly qualified author on a much neglected portion of the human anatomy. It is the ideal prescription for the manuscripts desired by all medical-book publishers, and it is truly fulfilled in this 200-page book, profusely and well illustrated. It matters little that the so-called "deficiency states," mesenteric lesions, hypoproteinemia and other conditions all present a similar x-ray pattern. The chief value of this book is that it focuses

attention on disorders of motor function in the small bowel and details methods of study and analysis that may result in definite clinical dividends, as well as the accumulation of factual physiologic data.

There are excellent chapters on the anatomy and physiology of the small bowel, on the use of the Miller-Abbott tube and on all the various pathologic processes that may involve this clinical terra incognita.

This monograph is a great credit to the author and should be a source of pride to the publishers, as it is well and accurately put together. Of interest and value chiefly to radiologists, it should be owned and carefully studied by all physicians who try to diagnose or treat gastrointestinal disease.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

The Fundamentals of Electrocardiographic Interpretation. By J. Bailey Carter, M.D., assistant (Rush) professor, Department of Medicine, University of Illinois College of Medicine and member of attending staff, Cook County and Augustana hospitals, Chicago. With a foreword by Horatio B. Williams, M.D., Dalton Professor of Physiology, College of Physicians and Surgeons, Columbia University, New York. Second edition. 8°, cloth, 406 pp., with 307 illustrations. Springfield, Illinois: Charles C. Thomas, 1945. \$6.00.

This second edition of a manual first published in 1937 has been thoroughly revised and brought up to date. The book is not a report of research, and debatable questions have been avoided. The manual is designed to aid the beginner in acquiring a practical working knowledge of the subject. Much of the material concerning coronary disease is new or has been rewritten. Many new illustrations have been added, and the extensive bibliographies appended to each chapter have been brought up to date.

Common Ailments of Man. Edited by Morris Fishbein, M.D. 8°, cloth, 177 pp., illustrated. Garden City: Garden City Publishing Company, Incorporated, 1945. \$1.00.

This popular manual has been designed to further the layman's knowledge of the ills that are likely to beset him. The various articles on common ailments by recognized medical specialists have been reprinted from *Hysgia*.

Penicillin and Other Antibiotic Agents. By Wallace E. Herrell, M.D., M.S., assistant professor of medicine, Mayo Foundation, University of Minnesota, and consultant in medicine, Mayo Clinic, Rochester, Minnesota. 8°, cloth, 348 pp., with 45 illustrations and 45 tables. Philadelphia: W. B. Saunders Company, 1945. \$5.00.

In this monograph Dr. Herrell has tried to bring together the fundamental, experimental and clinical studies that have been carried on with penicillin and other antibiotic agents. The book is divided into four parts. The first has to do with the history, preparation and chemistry of penicillin. The second and third, comprising the major portion of the text, concerns the clinical use of penicillin. The fourth discusses other antibiotic agents, including tyrothricin, streptothricin, streptomycin and other miscellaneous agents.

Physical Diagnosis. By Ralph H. Major, M.D., professor of medicine, University of Kansas. Third edition revised. 8°, cloth, 444 pp., with 458 illustrations. Philadelphia: W. B. Saunders Company, 1945. \$5.00.

This third edition of a standard text has been revised in the light of recent advances since the publication of the second edition in 1940.

Principles of Psychology for the Basic Course in Nursing
By Rev J Edward Rauth, O S B, Ph D, and Sister M Maurice Sheehy, R S M, R N, Ph D, assistant professor of nursing education, Catholic University of America 12°, cloth, 200 pp, with 18 illustrations and 8 tables Milwaukee The Bruce Publishing Company, 1945 \$2.00

This small manual is based on the authors' experience in teaching psychology in schools of nursing. It is designed as a teaching manual, and the applications of psychological principles of various nursing situations have been indicated in the text and a few case histories have been included. This text is not a book for self-study but is intended to be used as a basis for discussion with the teacher.

Bronchial Asthma By Leon Unger, M.D., assistant professor, Department of Medicine, Northwestern University Medical School, Chicago. With an introduction by Morris Fishbein, M.D., editor, *Journal of the American Medical Association* 8°, cloth, 724 pp, with 126 figures Springfield, Illinois Charles C Thomas, 1945 \$9.00

This work on bronchial asthma has been written from the viewpoint of allergy, and the author has endeavored to present a comprehensive treatise on his subject. Extended discussion is given to etiology, including constitutional and exciting factors. The exciting factors are divided into inhalants (allergens), ingestants (foods and drugs) and miscellaneous (silk, parasites, physical agents and bacteria). The author believes that the most important causes of asthma are the inhalants or allergens, and these substances are described in considerable detail. Following are extensive chapters on diagnosis, symptomatology, pathology and treatment (specific and nonspecific), including the sources of allergens, elimination diets, patent medicines used in asthma, and physical exercises for asthmatics. The laboratory section describes the preparation of extracts. There are chapters on other allergic diseases related to asthma and on the military aspects of the disease. The beginning chapters consider the technical terms used and their interpretation, as well as the history of bronchial asthma from ancient times to the present. Selected references are appended to each chapter and the printing is well done, with a good type on good paper. Dr Morris Fishbein in his introduction characterizes the work as the most complete consideration of the subject thus far available in any single book.

NOTICES

FELLOWSHIPS FOR THE STUDY OF RHEUMATIC FEVER

The American Council on Rheumatic Fever of the American Heart Association announces that applications for American Legion fellowships for the study of rheumatic fever will be accepted from recognized institutions concerned with the study of rheumatic fever and rheumatic heart disease. Two fellowships are available, each is for a period of three years and carries a stipend of \$3500, \$4000 and \$5000 for the first, second and third years respectively.

Each application should supply information concerning the institution, the projected study and the individual proposed for the fellowship. Applications will be received until August 1, 1946, and will become effective September 1, 1946.

These fellowships have been made available by a grant from the American Legion and the Women's Auxiliary of the American Legion as part of their program of fostering research in rheumatic fever and rheumatic heart disease.

INDUSTRIAL HEALTH CONGRESS

The seventh Annual Congress on Industrial Health will be held in Boston September 30 through October 3 at the Copley-Plaza Hotel, under the sponsorship of the Council on Industrial Health of the American Medical Association.

The program, as in the past, will include speakers of national note and is expected to attract hundreds of medical men, nurses, hygienists and, in addition, legislators, industrialists and others interested in the field of health in industry.

At a later date further announcements relative to the exact program will be made in the *Journal*. Because of the importance of the meeting, those expecting to attend are urged to make their hotel and transportation plans as early as possible.

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Tuesday, July 9, at 11:00 a.m. in the classroom of the Nurses' Residence. Dr Edwin B. Astwood will speak on the subject "Thiouracil in the Treatment of Hyperthyroidism." Dr Merry Pittman will be chairman.

ANNOUNCEMENTS

Dr Franklin G. Balch, Jr., has returned from naval duty and will resume the practice of surgery at 330 Dartmouth Street, Boston.

Dr Francis F. Cary announces the opening of an office for the practice of internal medicine in the Professional Building, 58 Federal Street, Greenfield.

Dr James Harrison announces his return from military service and the reopening of his office for the practice of medicine at 69 Bridge Street, Dedham.

Dr A. Macaluso, having been released from active service in the U. S. Naval Reserve, announces his return to practice with an office at 484 Commonwealth Avenue, Boston.
